The **font** IDL attribute, on setting, must be parsed as a CSS <'font'> value (but without supporting property-independent style sheet syntax like 'inherit'), and the resulting font must be assigned to the context, with the 'line-height' component forced to 'normal', with the 'font-size' component converted to CSS pixels, and with system fonts being computed to explicit values. If the new value is syntactically incorrect (including using property-independent style sheet syntax like 'inherit' or 'initial'), then it must be ignored, without assigning a new font value. [CSS][p1411]

Font family names must be interpreted in the context of the font style source object[p680] when the font is to be used; any fonts embedded using `@font-face` or loaded using `FontFace`[p66] objects that are visible to the font style source object[p680] must therefore be available once they are loaded. (Each font style source object[p680] has a font source, which determines what fonts are available.) If a font is used before it is fully loaded, or if the font style source object[p680] does not have that font in scope at the time the font is to be used, then it must be treated as if it was an unknown font, falling back to another as described by the relevant CSS specifications. [CSSFONTS][p1411] [CSSFONTLOAD][p1411]

On getting, the `font`[p680] attribute must return the serialized form of the current font of the context (with no 'line-height' component). [CSSOM][p1412]

Example

For example, after the following statement:

```
context.font = 'italic 400 12px/2 Unknown Font, sans-serif';
```

...the expression `context.font` would evaluate to the string "`italic 12px "Unknown Font", sans-serif`". The "400" font-weight doesn't appear because that is the default value. The line-height doesn't appear because it is forced to "normal", the default value.

When the object implementing the `CanvasTextDrawingStyles`[p669] interface is created, the font of the context must be set to 10px sans-serif. When the 'font-size' component is set to lengths using percentages, 'em' or 'ex' units, or the 'larger' or 'smaller' keywords, these must be interpreted relative to the computed value of the 'font-size' property of the font style source object[p680] at the time that the attribute is set, if it is an element. When the 'font-weight' component is set to the relative values 'bolder' and 'lighter', these must be interpreted relative to the computed value of the 'font-weight' property of the font style source object[p680] at the time that the attribute is set, if it is an element. If the computed values are undefined for a particular case (e.g. because the font style source object[p680] is not an element or is not being rendered[p1325]), then the relative keywords must be interpreted relative to the normal-weight 10px sans-serif default.

The **`textAlign`** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the `CanvasTextDrawingStyles`[p669] interface is created, the `textAlign`[p681] attribute must initially have the value `start`[p682].

The **`textBaseline`** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the `CanvasTextDrawingStyles`[p669] interface is created, the `textBaseline`[p681] attribute must initially have the value `alphabetic`[p683].

The **`direction`** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the `CanvasTextDrawingStyles`[p669] interface is created, the `direction`[p681] attribute must initially have the value "`inherit`[p683]".

Objects that implement the `CanvasTextDrawingStyles`[p669] interface have attributes that control the spacing between letters and words. Such objects have associated **letter spacing** and **word spacing** values, which are CSS <length> values. Initially, both must be the result of parsing "`0px`" as a CSS <length>.

The **`letterSpacing`**[p681] getter steps are to return the serialized form of this's letter spacing[p681].

The `letterSpacing`[p681] setter steps are:

1. Let *parsed* be the result of parsing the given value as a CSS <length>.
2. If *parsed* is failure, then return.
3. Set this's letter spacing[p681] to *parsed*.

The **`wordSpacing`**[p681] getter steps are to return the serialized form of this's word spacing[p681].

The `wordSpacing`[p681] setter steps are:

1. Let *parsed* be the result of parsing the given value as a CSS <length>.
2. If *parsed* is failure, then return.
3. Set this's word spacing[p681] to *parsed*.

The **`fontKerning`** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new

value. When the object implementing the CanvasTextDrawingStyles[p669] interface is created, the fontKerning[p681] attribute must initially have the value "auto[p683]".

The **fontStretch** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles[p669] interface is created, the fontStretch[p682] attribute must initially have the value "normal[p683]".

The **fontVariantCaps** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles[p669] interface is created, the fontVariantCaps[p682] attribute must initially have the value "normal[p684]".

The **textRendering** IDL attribute, on getting, must return the current value. On setting, the current value must be changed to the new value. When the object implementing the CanvasTextDrawingStyles[p669] interface is created, the textRendering[p682] attribute must initially have the value "auto[p684]".

The textAlign[p681] attribute's allowed keywords are as follows:

start
: Align to the start edge of the text (left side in left-to-right text, right side in right-to-left text).

end
: Align to the end edge of the text (right side in left-to-right text, left side in right-to-left text).

left
: Align to the left.

right
: Align to the right.

center
: Align to the center.

The textBaseline[p681] attribute's allowed keywords correspond to alignment points in the font:

The keywords map to these alignment points as follows:

top
: The top of the em square

hanging
: The hanging baseline

middle
: The middle of the em square

alphabetic

The alphabetic baseline

ideographic

The ideographic-under baseline

bottom

The bottom of the em square

The `direction`[p681] attribute's allowed keywords are as follows:

ltr

Treat input to the text preparation algorithm[p684] as left-to-right text.

rtl

Treat input to the text preparation algorithm[p684] as right-to-left text.

inherit

Default to the directionality of the `canvas`[p661] element or `Document`[p127] as appropriate.

The `fontKerning`[p681] attribute's allowed keywords are as follows:

auto

Kerning is applied at the discretion of the user agent.

normal

Kerning is applied.

none

Kerning is not applied.

The `fontStretch`[p682] attribute's allowed keywords are as follows:

ultra-condensed

Same as CSS 'font-stretch' 'ultra-condensed' setting.

extra-condensed

Same as CSS 'font-stretch' 'extra-condensed' setting.

condensed

Same as CSS 'font-stretch' 'condensed' setting.

semi-condensed

Same as CSS 'font-stretch' 'semi-condensed' setting.

normal

The default setting, where width of the glyphs is at 100%.

semi-expanded

Same as CSS 'font-stretch' 'semi-expanded' setting.

expanded

Same as CSS 'font-stretch' 'expanded' setting.

extra-expanded

Same as CSS 'font-stretch' 'extra-expanded' setting.

ultra-expanded

Same as CSS 'font-stretch' 'ultra-expanded' setting.

The `fontVariantCaps`[p682] attribute's allowed keywords are as follows:

normal

None of the features listed below are enabled.

small-caps

Same as CSS 'font-variant-caps' 'small-caps' setting.

all-small-caps

Same as CSS 'font-variant-caps' 'all-small-caps' setting.

petite-caps

Same as CSS 'font-variant-caps' 'petite-caps' setting.

all-petite-caps

Same as CSS 'font-variant-caps' 'all-petite-caps' setting.

unicase

Same as CSS 'font-variant-caps' 'unicase' setting.

titling-caps

Same as CSS 'font-variant-caps' 'titling-caps' setting.

The `textRendering`[p682] attribute's allowed keywords are as follows:

auto

Same as 'auto' in SVG text-rendering property.

optimizeSpeed

Same as 'optimizeSpeed' in SVG text-rendering property.

optimizeLegibility

Same as 'optimizeLegibility' in SVG text-rendering property.

geometricPrecision

Same as 'geometricPrecision' in SVG text-rendering property.

The **text preparation algorithm** is as follows. It takes as input a string *text*, a `CanvasTextDrawingStyles`[p669] object *target*, and an optional length *maxWidth*. It returns an array of glyph shapes, each positioned on a common coordinate space, a *physical alignment* whose value is one of *left*, *right*, and *center*, and an inline box. (Most callers of this algorithm ignore the *physical alignment* and the inline box.)

1. If *maxWidth* was provided but is less than or equal to zero or equal to NaN, then return an empty array.
2. Replace all ASCII whitespace in *text* with U+0020 SPACE characters.
3. Let *font* be the current font of *target*, as given by that object's `font`[p680] attribute.
4. Apply the appropriate step from the following list to determine the value of *direction*:

   ↪ **If the *target* object's `direction`[p681] attribute has the value "`ltr`[p683]"**

   Let *direction* be 'ltr[p157]'.

   ↪ **If the *target* object's `direction`[p681] attribute has the value "`rtl`[p683]"**

   Let *direction* be 'rtl[p157]'.

   ↪ **If the *target* object's font style source object[p680] is an element**

   Let *direction* be the directionality[p157] of the *target* object's font style source object[p680].

   ↪ **If the *target* object's font style source object[p680] is a `Document`[p127] with a non-null document element**

   Let *direction* be the directionality[p157] of the *target* object's font style source object[p680]'s document element.

   ↪ **Otherwise**

   Let *direction* be 'ltr[p157]'.

5. Form a hypothetical infinitely-wide CSS line box containing a single inline box containing the text *text*, with its CSS properties set as follows:

Property	Source
'direction'	*direction*
'font'	*font*
'font-kerning'	*target*'s fontKerning[p681]
'font-stretch'	*target*'s fontStretch[p682]
'font-variant-caps'	*target*'s fontVariantCaps[p682]
'letter-spacing'	*target*'s letter spacing[p681]
SVG text-rendering	*target*'s textRendering[p682]
'white-space'	'pre'
'word-spacing'	*target*'s word spacing[p681]

and with all other properties set to their initial values.

6. If *maxWidth* was provided and the hypothetical width of the inline box in the hypothetical line box is greater than *maxWidth* CSS pixels, then change *font* to have a more condensed font (if one is available or if a reasonably readable one can be synthesized by applying a horizontal scale factor to the font) or a smaller font, and return to the previous step.

7. The *anchor point* is a point on the inline box, and the *physical alignment* is one of the values *left*, *right*, and *center*. These variables are determined by the textAlign[p681] and textBaseline[p681] values as follows:

   Horizontal position:

   If textAlign[p681] is left[p682]

   If textAlign[p681] is start[p682] and *direction* is 'ltr'

   If textAlign[p681] is end[p682] and *direction* is 'rtl'

   Let the *anchor point*'s horizontal position be the left edge of the inline box, and let *physical alignment* be *left*.

   If textAlign[p681] is right[p682]

   If textAlign[p681] is end[p682] and *direction* is 'ltr'

   If textAlign[p681] is start[p682] and *direction* is 'rtl'

   Let the *anchor point*'s horizontal position be the right edge of the inline box, and let *physical alignment* be *right*.

   If textAlign[p681] is center[p682]

   Let the *anchor point*'s horizontal position be half way between the left and right edges of the inline box, and let *physical alignment* be *center*.

   Vertical position:

   If textBaseline[p681] is top[p682]

   Let the *anchor point*'s vertical position be the top of the em box of the first available font of the inline box.

   If textBaseline[p681] is hanging[p682]

   Let the *anchor point*'s vertical position be the hanging baseline of the first available font of the inline box.

   If textBaseline[p681] is middle[p682]

   Let the *anchor point*'s vertical position be half way between the bottom and the top of the em box of the first available font of the inline box.

   If textBaseline[p681] is alphabetic[p683]

   Let the *anchor point*'s vertical position be the alphabetic baseline of the first available font of the inline box.

   If textBaseline[p681] is ideographic[p683]

   Let the *anchor point*'s vertical position be the ideographic-under baseline of the first available font of the inline box.

   If textBaseline[p681] is bottom[p683]

   Let the *anchor point*'s vertical position be the bottom of the em box of the first available font of the inline box.

8. Let *result* be an array constructed by iterating over each glyph in the inline box from left to right (if any), adding to the array, for each glyph, the shape of the glyph as it is in the inline box, positioned on a coordinate space using CSS pixels with its origin is at the *anchor point*.

9. Return *result*, *physical alignment*, and the inline box.

4.12.5.1.5 Building paths §[p686]

Objects that implement the CanvasPath[p669] interface have a path[p686]. A **path** has a list of zero or more subpaths. Each subpath consists of a list of one or more points, connected by straight or curved **line segments**, and a flag indicating whether the subpath is closed or not. A closed subpath is one where the last point of the subpath is connected to the first point of the subpath by a straight line. Subpaths with only one point are ignored when painting the path.

Paths[p686] have a **need new subpath** flag. When this flag is set, certain APIs create a new subpath rather than extending the previous one. When a path[p686] is created, its need new subpath[p686] flag must be set.

When an object implementing the CanvasPath[p669] interface is created, its path[p686] must be initialized to zero subpaths.

For web developers (non-normative)

***context*.moveTo[p688](*x*, *y*)**
***path*.moveTo[p688](*x*, *y*)**

Creates a new subpath with the given point.

***context*.closePath[p689]()**
***path*.closePath[p689]()**

Marks the current subpath as closed, and starts a new subpath with a point the same as the start and end of the newly closed subpath.

***context*.lineTo[p689](*x*, *y*)**
***path*.lineTo[p689](*x*, *y*)**

Adds the given point to the current subpath, connected to the previous one by a straight line.

***context*.quadraticCurveTo[p689](*cpx*, *cpy*, *x*, *y*)**
***path*.quadraticCurveTo[p689](*cpx*, *cpy*, *x*, *y*)**

Adds the given point to the current subpath, connected to the previous one by a quadratic Bézier curve with the given control point.

***context*.bezierCurveTo[p689](*cp1x*, *cp1y*, *cp2x*, *cp2y*, *x*, *y*)**
***path*.bezierCurveTo[p689](*cp1x*, *cp1y*, *cp2x*, *cp2y*, *x*, *y*)**

Adds the given point to the current subpath, connected to the previous one by a cubic Bézier curve with the given control points.

***context*.arcTo[p689](*x1*, *y1*, *x2*, *y2*, *radius*)**
***path*.arcTo[p689](*x1*, *y1*, *x2*, *y2*, *radius*)**

Adds an arc with the given control points and radius to the current subpath, connected to the previous point by a straight line.

Throws an "IndexSizeError" DOMException if the given radius is negative.

***context*.arc**[p690]**(*x*, *y*, *radius*, *startAngle*, *endAngle* [, *counterclockwise*])**

***path*.arc**[p690]**(*x*, *y*, *radius*, *startAngle*, *endAngle* [, *counterclockwise*])**

Adds points to the subpath such that the arc described by the circumference of the circle described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an `"IndexSizeError"` `DOMException` if the given radius is negative.

***context*.ellipse**[p690]**(*x*, *y*, *radiusX*, *radiusY*, *rotation*, *startAngle*, *endAngle* [, *counterclockwise*])**
***path*.ellipse**[p690]**(*x*, *y*, *radiusX*, *radiusY*, *rotation*, *startAngle*, *endAngle* [, *counterclockwise*])**

Adds points to the subpath such that the arc described by the circumference of the ellipse described by the arguments, starting at the given start angle and ending at the given end angle, going in the given direction (defaulting to clockwise), is added to the path, connected to the previous point by a straight line.

Throws an "IndexSizeError" DOMException if the given radius is negative.

***context*.rect**[p690]**(*x*, *y*, *w*, *h*)**
***path*.rect**[p690]**(*x*, *y*, *w*, *h*)**

Adds a new closed subpath to the path, representing the given rectangle.

***context*.roundRect**[p691]**(*x*, *y*, *w*, *h*, *radii*)**
***path*.roundRect**[p691]**(*x*, *y*, *w*, *h*, *radii*)**

Adds a new closed subpath to the path representing the given rounded rectangle. *radii* is either a list of radii or a single radius representing the corners of the rectangle in pixels. If a list is provided, the number and order of these radii function in the same way as the CSS 'border-radius' property. A single radius behaves the same way as a list with a single element.

If *w* and *h* are both greater than or equal to 0, or if both are smaller than 0, then the path is drawn clockwise. Otherwise, it is drawn counterclockwise.

When *w* is negative, the rounded rectangle is flipped horizontally, which means that the radius values that normally apply to the left corners are used on the right and vice versa. Similarly, when *h* is negative, the rounded rect is flipped vertically.

When a value *r* in *radii* is a number, the corresponding corner(s) are drawn as circular arcs of radius *r*.

When a value *r* in *radii* is an object with `{ x, y }` properties, the corresponding corner(s) are drawn as elliptical arcs whose *x* and *y* radii are equal to *r.x* and *r.y*, respectively.

When the sum of the *radii* of two corners of the same edge is greater than the length of the edge, all the *radii* of the rounded rectangle are scaled by a factor of length / (*r1* + *r2*). If multiple edges have this property, the scale factor of the edge with the smallest scale factor is used. This is consistent with CSS behavior.

Throws a RangeError if *radii* is a list whose size is not one, two, three, or four.

Throws a RangeError if a value in *radii* is a negative number, or is an `{ x, y }` object whose `x` or `y` properties are negative numbers.

The following methods allow authors to manipulate the paths[p686] of objects implementing the CanvasPath[p669] interface.

For objects implementing the CanvasDrawPath[p668] and CanvasTransform[p667] interfaces, the points passed to the methods, and the resulting lines added to current default path[p703] by these methods, must be transformed according to the current transformation matrix[p693] before being added to the path.

The **moveTo(*x*, *y*)** method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.

2. Create a new subpath with the specified point as its first (and only) point.

When the user agent is to **ensure there is a subpath** for a coordinate (*x*, *y*) on a path[p686], the user agent must check to see if the path[p686] has its need new subpath[p686] flag set. If it does, then the user agent must create a new subpath with the point (*x*, *y*) as its first (and only) point, as if the `moveTo()`[p688] method had been called, and must then unset the path[p686]'s need new subpath[p686] flag.

The **`closePath()`** method, when invoked, must do nothing if the object's path has no subpaths. Otherwise, it must mark the last subpath as closed, create a new subpath whose first point is the same as the previous subpath's first point, and finally add this new subpath to the path.

Note

If the last subpath had more than one point in its list of points, then this is equivalent to adding a straight line connecting the last point back to the first point of the last subpath, thus "closing" the subpath.

New points and the lines connecting them are added to subpaths using the methods described below. In all cases, the methods only modify the last subpath in the object's path.

The **`lineTo(x, y)`** method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. If the object's path has no subpaths, then ensure there is a subpath[p689] for (*x*, *y*).
3. Otherwise, connect the last point in the subpath to the given point (*x*, *y*) using a straight line, and then add the given point (*x*, *y*) to the subpath.

The **`quadraticCurveTo(cpx, cpy, x, y)`** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Ensure there is a subpath[p689] for (*cpx*, *cpy*)
3. Connect the last point in the subpath to the given point (*x*, *y*) using a quadratic Bézier curve with control point (*cpx*, *cpy*). [BEZIER][p1410]
4. Add the given point (*x*, *y*) to the subpath.

The **`bezierCurveTo(cp1x, cp1y, cp2x, cp2y, x, y)`** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Ensure there is a subpath[p689] for (*cp1x*, *cp1y*).
3. Connect the last point in the subpath to the given point (*x*, *y*) using a cubic Bézier curve with control points (*cp1x*, *cp1y*) and (*cp2x*, *cp2y*). [BEZIER][p1410]
4. Add the point (*x*, *y*) to the subpath.

The **`arcTo(x1, y1, x2, y2, radius)`** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Ensure there is a subpath[p689] for (*x1*, *y1*).
3. If *radius* is negative, then throw an `"IndexSizeError"` `DOMException`.
4. Let the point (*x0*, *y0*) be the last point in the subpath, transformed by the inverse of the current transformation matrix[p693] (so that it is in the same coordinate system as the points passed to the method).
5. If the point (*x0*, *y0*) is equal to the point (*x1*, *y1*), or if the point (*x1*, *y1*) is equal to the point (*x2*, *y2*), or if *radius* is zero, then add the point (*x1*, *y1*) to the subpath, and connect that point to the previous point (*x0*, *y0*) by a straight line.
6. Otherwise, if the points (*x0*, *y0*), (*x1*, *y1*), and (*x2*, *y2*) all lie on a single straight line, then add the point (*x1*, *y1*) to the subpath, and connect that point to the previous point (*x0*, *y0*) by a straight line.

7. Otherwise, let *The Arc* be the shortest arc given by circumference of the circle that has radius *radius*, and that has one point tangent to the half-infinite line that crosses the point (*x0*, *y0*) and ends at the point (*x1*, *y1*), and that has a different point tangent to the half-infinite line that ends at the point (*x1*, *y1*) and crosses the point (*x2*, *y2*). The points at which this circle touches these two lines are called the start and end tangent points respectively. Connect the point (*x0*, *y0*) to the start tangent point by a straight line, adding the start tangent point to the subpath, and then connect the start tangent point to the end tangent point by *The Arc*, adding the end tangent point to the subpath.

The **`arc(x, y, radius, startAngle, endAngle, counterclockwise)`** method, when invoked, must run the ellipse method steps[p690] with this, *x*, *y*, *radius*, *radius*, 0, *startAngle*, *endAngle*, and *counterclockwise*.

Note

This makes it equivalent to `ellipse()`[p690] *except that both radii are equal and* rotation *is 0.*

The **`ellipse(x, y, radiusX, radiusY, rotation, startAngle, endAngle, counterclockwise)`** method, when invoked, must run the ellipse method steps[p690] with this, *x*, *y*, *radiusX*, *radiusY*, *rotation*, *startAngle*, *endAngle*, and *counterclockwise*.

The **determine the point on an ellipse steps**, given *ellipse*, and *angle*, are:

1. Let *eccentricCircle* be the circle that shares its origin with *ellipse*, with a radius equal to the semi-major axis of *ellipse*.
2. Let *outerPoint* be the point on *eccentricCircle*'s circumference at *angle* measured in radians clockwise from *ellipse*'s semi-major axis.
3. Let *chord* be the line perpendicular to *ellipse*'s major axis between this axis and *outerPoint*.
4. Return the point on *chord* that crosses *ellipse*'s circumference.

The **ellipse method steps**, given *canvasPath*, *x*, *y*, *radiusX*, *radiusY*, *rotation*, *startAngle*, *endAngle*, and *counterclockwise*, are:

1. If any of the arguments are infinite or NaN, then return.
2. If either *radiusX* or *radiusY* are negative, then throw an `"IndexSizeError"` `DOMException`.
3. If *canvasPath*'s path has any subpaths, then add a straight line from the last point in the subpath to the start point of the arc.
4. Add the start and end points of the arc to the subpath, and connect them with an arc. The arc and its start and end points are defined as follows:

   Consider an ellipse that has its origin at (*x*, *y*), that has a major-axis radius *radiusX* and a minor-axis radius *radiusY*, and that is rotated about its origin such that its semi-major axis is inclined *rotation* radians clockwise from the x-axis.

   If *counterclockwise* is false and *endAngle* − *startAngle* is equal to or greater than 2π, or, if *counterclockwise* is *true* and *startAngle* − *endAngle* is equal to or greater than 2π, then the arc is the whole circumference of this ellipse, and both the start point and the end point are the result of running the determine the point on an ellipse steps[p690] given this ellipse and *startAngle*.

   Otherwise, the start point is the result of running the determine the point on an ellipse steps[p690] given this ellipse and *startAngle*, the end point is the result of running the determine the point on an ellipse steps[p690] given this ellipse and *endAngle*, and the arc is the path along the circumference of this ellipse from the start point to the end point, going counterclockwise if *counterclockwise* is true, and clockwise otherwise. Since the points are on the ellipse, as opposed to being simply angles from zero, the arc can never cover an angle greater than 2π radians.

   Note

   Even if the arc covers the entire circumference of the ellipse and there are no other points in the subpath, the path is not closed unless the `closePath()`[p689] *method is appropriately invoked.*

The **`rect(x, y, w, h)`** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Create a new subpath containing just the four points (*x*, *y*), (*x*+*w*, *y*), (*x*+*w*, *y*+*h*), (*x*, *y*+*h*), in that order, with those four points connected by straight lines.

3. Mark the subpath as closed.
4. Create a new subpath with the point (*x*, *y*) as the only point in the subpath.

The **`roundRect(x, y, w, h, radii)`** method steps are:

1. If any of *x*, *y*, *w*, or *h* are infinite or NaN, then return.
2. If *radii* is an `unrestricted double` or `DOMPointInit`, then set *radii* to « *radii* ».
3. If *radii* is not a list of size one, two, three, or four, then throw a `RangeError`.
4. Let *normalizedRadii* be an empty list.
5. For each *radius* of *radii*:
    1. If *radius* is a `DOMPointInit`:
        1. If *radius*["x"] or *radius*["y"] is infinite or NaN, then return.
        2. If *radius*["x"] or *radius*["y"] is negative, then throw a `RangeError`.
        3. Otherwise, append *radius* to *normalizedRadii*.
    2. If *radius* is a `unrestricted double`:
        1. If *radius* is infinite or NaN, then return.
        2. If *radius* is negative, then throw a `RangeError`.
        3. Otherwise append «["x" → *radius*, "y" → *radius*]» to *normalizedRadii*.
6. Let *upperLeft*, *upperRight*, *lowerRight*, and *lowerLeft* be null.
7. If *normalizedRadii*'s size is 4, then set *upperLeft* to *normalizedRadii*[0], set *upperRight* to *normalizedRadii*[1], set *lowerRight* to *normalizedRadii*[2], and set *lowerLeft* to *normalizedRadii*[3].
8. If *normalizedRadii*'s size is 3, then set *upperLeft* to *normalizedRadii*[0], set *upperRight* and *lowerLeft* to *normalizedRadii*[1], and set *lowerRight* to *normalizedRadii*[2].
9. If *normalizedRadii*'s size is 2, then set *upperLeft* and *lowerRight* to *normalizedRadii*[0] and set *upperRight* and *lowerLeft* to *normalizedRadii*[1].
10. If *normalizedRadii*'s size is 1, then set *upperLeft*, *upperRight*, *lowerRight*, and *lowerLeft* to *normalizedRadii*[0].
11. Corner curves must not overlap. Scale all radii to prevent this:
    1. Let *top* be *upperLeft*["x"] + *upperRight*["x"].
    2. Let *right* be *upperRight*["y"] + *lowerRight*["y"].
    3. Let *bottom* be *lowerRight*["x"] + *lowerLeft*["x"].
    4. Let *left* be *upperLeft*["y"] + *lowerLeft*["y"].
    5. Let *scale* be the minimum value of the ratios *w* / *top*, *h* / *right*, *w* / *bottom*, *h* / *left*.
    6. If *scale* is less than 1, then set the x and y members of *upperLeft*, *upperRight*, *lowerLeft*, and *lowerRight* to their current values multiplied by *scale*.
12. Create a new subpath:
    1. Move to the point (*x* + *upperLeft*["x"], *y*).
    2. Draw a straight line to the point (*x* + *w* − *upperRight*["x"], *y*).
    3. Draw an arc to the point (*x* + *w*, *y* + *upperRight*["y"]).
    4. Draw a straight line to the point (*x* + *w*, *y* + *h* − *lowerRight*["y"]).
    5. Draw an arc to the point (*x* + *w* − *lowerRight*["x"], *y* + *h*).
    6. Draw a straight line to the point (*x* + *lowerLeft*["x"], *y* + *h*).

7. Draw an arc to the point (x, $y + h - lowerLeft$["y[p66]"]).
8. Draw a straight line to the point (x, $y + upperLeft$["y[p66]"]).
9. Draw an arc to the point ($x + upperLeft$["x[p66]"], y).

13. Mark the subpath as closed.
14. Create a new subpath with the point (x, y) as the only point in the subpath.

Note

This is designed to behave similarly to the CSS 'border-radius' property.

✔ MDN

4.12.5.1.6 `Path2D`[p670] *objects* §[p692]

`Path2D`[p670] objects can be used to declare paths that are then later used on objects implementing the `CanvasDrawPath`[p668] interface. In addition to many of the APIs described in earlier sections, `Path2D`[p670] objects have methods to combine paths, and to add text to paths.

For web developers (non-normative)

***path* = new `Path2D`[p692]()**

Creates a new empty `Path2D`[p670] object.

***path* = new `Path2D`[p692](*path*)**

When *path* is a `Path2D`[p670] object, returns a copy.

When *path* is a string, creates the path described by the argument, interpreted as SVG path data. [SVG][p1417]

***path*.`addPath`[p692](*path* [, *transform*])**

Adds to the path the path given by the argument.

The **`Path2D(path)`** constructor, when invoked, must run these steps:

1. Let *output* be a new `Path2D`[p670] object.
2. If *path* is not given, then return *output*.
3. If *path* is a `Path2D`[p670] object, then add all subpaths of *path* to *output* and return *output*. (In other words, it returns a copy of the argument.)
4. Let *svgPath* be the result of parsing and interpreting *path* according to *SVG 2*'s rules for path data. [SVG][p1417]

   Note

   The resulting path could be empty. SVG defines error handling rules for parsing and applying path data.

5. Let (x, y) be the last point in *svgPath*.
6. Add all the subpaths, if any, from *svgPath* to *output*.
7. Create a new subpath in *output* with (x, y) as the only point in the subpath.
8. Return *output*.

The **`addPath(path, transform)`** method, when invoked on a `Path2D`[p670] object *a*, must run these steps:

1. If the `Path2D`[p670] object *path* has no subpaths, then return.
2. Let *matrix* be the result of creating a `DOMMatrix` from the 2D dictionary *transform*.
3. If one or more of *matrix*'s m11 element, m12 element, m21 element, m22 element, m41 element, or m42 element are infinite or NaN, then return.
4. Create a copy of all the subpaths in *path*. Let this copy be known as *c*.
5. Transform all the coordinates and lines in *c* by the transform matrix *matrix*.

6. Let (x, y) be the last point in the last subpath of c.

7. Add all the subpaths in c to a.

8. Create a new subpath in a with (x, y) as the only point in the subpath.

4.12.5.1.7 Transformations §p693

Objects that implement the CanvasTransform[p667] interface have a **current transformation matrix**, as well as methods (described in this section) to manipulate it. When an object implementing the CanvasTransform[p667] interface is created, its transformation matrix must be initialized to the identity matrix.

The current transformation matrix[p693] is applied to coordinates when creating the current default path[p703], and when painting text, shapes, and Path2D[p670] objects, on objects implementing the CanvasTransform[p667] interface.

The transformations must be performed in reverse order.

Note

For instance, if a scale transformation that doubles the width is applied to the canvas, followed by a rotation transformation that rotates drawing operations by a quarter turn, and a rectangle twice as wide as it is tall is then drawn on the canvas, the actual result will be a square.

For web developers (non-normative)

***context*.scale[p693](*x*, *y*)**

Changes the current transformation matrix[p693] to apply a scaling transformation with the given characteristics.

***context*.rotate[p693](*angle*)**

Changes the current transformation matrix[p693] to apply a rotation transformation with the given characteristics. The angle is in radians.

***context*.translate[p694](*x*, *y*)**

Changes the current transformation matrix[p693] to apply a translation transformation with the given characteristics.

***context*.transform[p694](*a*, *b*, *c*, *d*, *e*, *f*)**

Changes the current transformation matrix[p693] to apply the matrix given by the arguments as described below.

***matrix* = *context*.getTransform[p694]()**

Returns a copy of the current transformation matrix[p693], as a newly created DOMMatrix object.

***context*.setTransform[p694](*a*, *b*, *c*, *d*, *e*, *f*)**

Changes the current transformation matrix[p693] *to* the matrix given by the arguments as described below.

***context*.setTransform[p694](*transform*)**

Changes the current transformation matrix[p693] *to* the matrix represented by the passed DOMMatrix2DInit dictionary.

***context*.resetTransform[p694]()**

Changes the current transformation matrix[p693] to the identity matrix.

The **scale(*x*, *y*)** method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.

2. Add the scaling transformation described by the arguments to the current transformation matrix[p693]. The x argument represents the scale factor in the horizontal direction and the y argument represents the scale factor in the vertical direction. The factors are multiples.

The **rotate(*angle*)** method, when invoked, must run these steps:

1. If *angle* is infinite or NaN, then return.

2. Add the rotation transformation described by the argument to the current transformation matrix[p693]. The *angle* argument represents a clockwise rotation angle expressed in radians.

The **translate(*x*, *y*)** method, when invoked, must run these steps:

1. If either of the arguments are infinite or NaN, then return.
2. Add the translation transformation described by the arguments to the current transformation matrix[p693]. The *x* argument represents the translation distance in the horizontal direction and the *y* argument represents the translation distance in the vertical direction. The arguments are in coordinate space units.

The **transform(*a*, *b*, *c*, *d*, *e*, *f*)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Replace the current transformation matrix[p693] with the result of multiplying the current transformation matrix with the matrix described by:

$$\begin{matrix} a & c & e \\ b & d & f \\ 0 & 0 & 1 \end{matrix}$$

Note

The arguments a, b, c, d, e, *and* f *are sometimes called* m11, m12, m21, m22, dx, *and* dy *or* m11, m21, m12, m22, dx, *and* dy. *Care ought to be taken in particular with the order of the second and third arguments (*b *and* c*) as their order varies from API to API and APIs sometimes use the notation* m12/m21 *and sometimes* m21/m12 *for those positions.*

The **getTransform()** method, when invoked, must return a newly created `DOMMatrix` representing a copy of the current transformation matrix[p693] matrix of the context.

Note

This returned object is not live, so updating it will not affect the current transformation matrix[p693], and updating the current transformation matrix[p693] will not affect an already returned `DOMMatrix`.

The **setTransform(*a*, *b*, *c*, *d*, *e*, *f*)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Reset the current transformation matrix[p693] to the identity matrix.
3. Invoke the `transform`[p694]`(a, b, c, d, e, f)` method with the same arguments.

The **setTransform(*transform*)** method, when invoked, must run these steps:

1. Let *matrix* be the result of creating a `DOMMatrix` from the 2D dictionary *transform*.
2. If one or more of *matrix*'s m11 element, m12 element, m21 element, m22 element, m41 element, or m42 element are infinite or NaN, then return.
3. Reset the current transformation matrix[p693] to *matrix*.

The **resetTransform()** method, when invoked, must reset the current transformation matrix[p693] to the identity matrix.

Note

Given a matrix of the form created by the `transform()`[p694] *and* `setTransform()`[p694] *methods, i.e.,*

$$\begin{matrix} a & c & e \\ b & d & f \\ 0 & 0 & 1 \end{matrix}$$

the resulting transformed coordinates after transform matrix multiplication will be

$$x_{new} = a\,x + c\,y + e$$
$$y_{new} = b\,x + d\,y + f$$

4.12.5.1.8 Image sources for 2D rendering contexts §[p695]

Some methods on the CanvasDrawImage[p668] and CanvasFillStrokeStyles[p667] interfaces take the union type CanvasImageSource[p666] as an argument.

This union type allows objects implementing any of the following interfaces to be used as image sources:

- HTMLOrSVGImageElement[p666] (img[p338] or SVG image elements)
- HTMLVideoElement[p399] (video[p398] elements)
- HTMLCanvasElement[p661] (canvas[p661] elements)
- ImageBitmap[p1120]
- VideoFrame

Note

Although not formally specified as such, SVG image elements are expected to be implemented nearly identical to img[p338] elements. That is, SVG image elements share the fundamental concepts and features of img[p338] elements.

Note

The ImageBitmap[p1120] interface can be created from a number of other image-representing types, including ImageData[p670].

To **check the usability of the *image* argument**, where *image* is a CanvasImageSource[p666] object, run these steps:

1. Switch on *image*:

   ↪ **HTMLOrSVGImageElement[p666]**

   If *image*'s current request[p356]'s state[p356] is broken[p356], then throw an "InvalidStateError" DOMException.

   If *image* is not fully decodable[p356], then return *bad*.

   If *image* has a natural width or natural height (or both) equal to zero, then return *bad*.

   ↪ **HTMLVideoElement[p399]**

   If *image*'s readyState[p427] attribute is either HAVE_NOTHING[p425] or HAVE_METADATA[p425], then return *bad*.

   ↪ **HTMLCanvasElement[p661]**

   ↪ **OffscreenCanvas[p725]**

   If *image* has either a horizontal dimension or a vertical dimension equal to zero, then throw an "InvalidStateError" DOMException.

   ↪ **ImageBitmap[p1120]**

   ↪ **VideoFrame**

   If *image*'s [[Detached]][p116] internal slot value is set to true, then throw an "InvalidStateError" DOMException.

2. Return *good*.

When a CanvasImageSource[p666] object represents an HTMLOrSVGImageElement[p666], the element's image must be used as the source image.

Specifically, when a CanvasImageSource[p666] object represents an animated image in an HTMLOrSVGImageElement[p666], the user agent must use the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation, when rendering the image for CanvasRenderingContext2D[p666] APIs.

When a CanvasImageSource[p666] object represents an HTMLVideoElement[p399], then the frame at the current playback position[p423] when the method with the argument is invoked must be used as the source image when rendering the image for CanvasRenderingContext2D[p666] APIs, and the source image's dimensions must be the natural width[p401] and natural height[p401] of the media resource[p407] (i.e., after any aspect-ratio correction has been applied).

When a CanvasImageSource[p666] object represents an HTMLCanvasElement[p661], the element's bitmap must be used as the source image.

When a CanvasImageSource[p666] object represents an element that is being rendered[p1325] and that element has been resized, the original image data of the source image must be used, not the image as it is rendered (e.g. width[p468] and height[p468] attributes on the source element have no effect on how the object is interpreted when rendering the image for CanvasRenderingContext2D[p666] APIs).

When a CanvasImageSource[p666] object represents an ImageBitmap[p1120], the object's bitmap image data must be used as the source image.

When a CanvasImageSource[p666] object represents a VideoFrame, the object's pixel data must be used as the source image, and the source image's dimensions must be the object's [[display width]] and [[display height]].

An object *image* **is not origin-clean** if, switching on *image*'s type:

↪ **HTMLOrSVGImageElement**[p666]

image's current request[p356]'s image data[p356] is CORS-cross-origin[p95].

↪ **HTMLVideoElement**[p399]

image's media data[p407] is CORS-cross-origin[p95].

↪ **HTMLCanvasElement**[p661]

↪ **ImageBitmap**[p1120]

image's bitmap's origin-clean[p663] flag is false.

4.12.5.1.9 Fill and stroke styles §[p696]

For web developers (non-normative)

***context*.fillStyle**[p696] **[= *value*]**

Returns the current style used for filling shapes.

Can be set, to change the fill style[p696].

The style can be either a string containing a CSS color, or a CanvasGradient[p670] or CanvasPattern[p670] object. Invalid values are ignored.

***context*.strokeStyle**[p697] **[= *value*]**

Returns the current style used for stroking shapes.

Can be set, to change the stroke style.[p696]

The style can be either a string containing a CSS color, or a CanvasGradient[p670] or CanvasPattern[p670] object. Invalid values are ignored.

Objects that implement the CanvasFillStrokeStyles[p667] interface have attributes and methods (defined in this section) that control how shapes are treated by the object.

Such objects have associated **fill style** and **stroke style** values, which are either CSS colors, CanvasPattern[p670]s, or CanvasGradient[p670]s. Initially, both must be the result of parsing[p61] the string "#000000".

When the value is a CSS color, it must not be affected by the transformation matrix when used to draw on bitmaps.

Note

When set to a CanvasPattern[p670] or CanvasGradient[p670] object, changes made to the object after the assignment do affect subsequent stroking or filling of shapes.

The **fillStyle** getter steps are:

1. If this's fill style[p696] is a CSS color, then return the serialization[p697] of that color.
2. Return this's fill style[p696].

The fillStyle[p696] setter steps are:

1. If the given value is a string, then:

    1. Let *parsedValue* be the result of parsing[p61] the given value with this's canvas[p673] attribute's value.
    2. If *parsedValue* is failure, then return.
    3. Set this's fill style[p696] to *parsedValue*.
    4. Return.
2. If the given value is a CanvasPattern[p670] object that is marked as not origin-clean[p699], then set this's origin-clean[p663] flag to false.
3. Set this's fill style[p696] to the given value.

The **strokeStyle** getter steps are:

1. If this's stroke style[p696] is a CSS color, then return the serialization[p697] of that color.
2. Return this's stroke style[p696].

The strokeStyle[p697] setter steps are:

1. If the given value is a string, then:
    1. Let *parsedValue* be the result of parsing[p61] the given value with this's canvas[p673] attribute's value.
    2. If *parsedValue* is failure, then return.
    3. Set this's stroke style[p696] to *parsedValue*.
    4. Return.
2. If the given value is a CanvasPattern[p670] object that is marked as not origin-clean[p699], then set this's origin-clean[p663] flag to false.
3. Set this's stroke style[p696] to the given value.

The **serialization of a color** for a color value is a string, computed as follows: if it has alpha equal to 1.0, then the string is a lowercase six-digit hex value, prefixed with a "#" character (U+0023 NUMBER SIGN), with the first two digits representing the red component, the next two digits representing the green component, and the last two digits representing the blue component, the digits being ASCII lower hex digits. Otherwise, the color value has alpha less than 1.0, and the string is the color value in the CSS `rgba()` functional-notation format: the literal string "`rgba`" (U+0072 U+0067 U+0062 U+0061) followed by a U+0028 LEFT PARENTHESIS, a base-ten integer in the range 0-255 representing the red component (using ASCII digits in the shortest form possible), a literal U+002C COMMA and U+0020 SPACE, an integer for the green component, a comma and a space, an integer for the blue component, another comma and space, a U+0030 DIGIT ZERO, if the alpha value is greater than zero then a U+002E FULL STOP (representing the decimal point), if the alpha value is greater than zero then one or more ASCII digits representing the fractional part of the alpha, and finally a U+0029 RIGHT PARENTHESIS. User agents must express the fractional part of the alpha value, if any, with the level of precision necessary for the alpha value, when reparsed, to be interpreted as the same alpha value.

There are three types of gradients, linear gradients, radial gradients, and conic gradients, represented by objects implementing the opaque CanvasGradient[p670] interface.

Once a gradient has been created (see below), stops are placed along it to define how the colors are distributed along the gradient. The color of the gradient at each stop is the color specified for that stop. Between each such stop, the colors and the alpha component must be linearly interpolated over the RGBA space without premultiplying the alpha value to find the color to use at that offset. Before the first stop, the color must be the color of the first stop. After the last stop, the color must be the color of the last stop. When there are no stops, the gradient is transparent black.

For web developers (non-normative)

***gradient*.addColorStop[p698](*offset*, *color*)**

Adds a color stop with the given color to the gradient at the given offset. 0.0 is the offset at one end of the gradient, 1.0 is the offset at the other end.

Throws an "IndexSizeError" DOMException if the offset is out of range. Throws a "SyntaxError" DOMException if the color cannot be parsed.

***gradient* = *context*.createLinearGradient[p698](*x0*, *y0*, *x1*, *y1*)**

Returns a CanvasGradient[p670] object that represents a linear gradient that paints along the line given by the coordinates represented by the arguments.

***gradient* = *context*.createRadialGradient[p698](*x0*, *y0*, *r0*, *x1*, *y1*, *r1*)**

Returns a CanvasGradient[p670] object that represents a radial gradient that paints along the cone given by the circles represented by the arguments.

If either of the radii are negative, throws an "IndexSizeError" DOMException exception.

***gradient* = *context*.createConicGradient[p699](*startAngle*, *x*, *y*)**

Returns a CanvasGradient[p670] object that represents a conic gradient that paints clockwise along the rotation around the center represented by the arguments.

The **addColorStop(*offset*, *color*)** method on the CanvasGradient[p670], when invoked, must run these steps:

1. If the *offset* is less than 0 or greater than 1, then throw an "IndexSizeError" DOMException.
2. Let *parsed color* be the result of parsing[p61] *color*.

   Note

   No element is passed to the parser because CanvasGradient[p670] objects are canvas[p661]-neutral — a CanvasGradient[p670] object created by one canvas[p661] can be used by another, and there is therefore no way to know which is the "element in question" at the time that the color is specified.

3. If *parsed color* is failure, throw a "SyntaxError" DOMException.
4. Place a new stop on the gradient, at offset *offset* relative to the whole gradient, and with the color *parsed color*.

   If multiple stops are added at the same offset on a gradient, then they must be placed in the order added, with the first one closest to the start of the gradient, and each subsequent one infinitesimally further along towards the end point (in effect causing all but the first and last stop added at each point to be ignored).

The **createLinearGradient(*x0*, *y0*, *x1*, *y1*)** method takes four arguments that represent the start point (*x0*, *y0*) and end point (*x1*, *y1*) of the gradient. The method, when invoked, must return a linear CanvasGradient[p670] initialized with the specified line.

Linear gradients must be rendered such that all points on a line perpendicular to the line that crosses the start and end points have the color at the point where those two lines cross (with the colors coming from the interpolation and extrapolation[p697] described above). The points in the linear gradient must be transformed as described by the current transformation matrix[p693] when rendering.

If $x0 = x1$ and $y0 = y1$, then the linear gradient must paint nothing.

The **createRadialGradient(*x0*, *y0*, *r0*, *x1*, *y1*, *r1*)** method takes six arguments, the first three representing the start circle with origin (*x0*, *y0*) and radius *r0*, and the last three representing the end circle with origin (*x1*, *y1*) and radius *r1*. The values are in coordinate space units. If either of *r0* or *r1* are negative, then an "IndexSizeError" DOMException must be thrown. Otherwise, the method, when invoked, must return a radial CanvasGradient[p670] initialized with the two specified circles.

Radial gradients must be rendered by following these steps:

1. If $x_0 = x_1$ and $y_0 = y_1$ and $r_0 = r_1$, then the radial gradient must paint nothing. Return.
2. Let $x(\omega) = (x_1 - x_0)\omega + x_0$

   Let $y(\omega) = (y_1 - y_0)\omega + y_0$

   Let $r(\omega) = (r_1 - r_0)\omega + r_0$

   Let the color at ω be the color at that position on the gradient (with the colors coming from the interpolation and extrapolation[p697] described above).
3. For all values of ω where $r(\omega) > 0$, starting with the value of ω nearest to positive infinity and ending with the value of ω nearest to negative infinity, draw the circumference of the circle with radius $r(\omega)$ at position $(x(\omega), y(\omega))$, with the color at ω, but only painting on the parts of the bitmap that have not yet been painted on by earlier circles in this step for this rendering of the gradient.

Note

This effectively creates a cone, touched by the two circles defined in the creation of the gradient, with the part of the cone before the start circle (0.0) using the color of the first offset, the part of the cone after the end circle (1.0) using the color of the last offset, and areas outside the cone untouched by the gradient (transparent black).

The resulting radial gradient must then be transformed as described by the current transformation matrix[p693] when rendering.

The **`createConicGradient(startAngle, x, y)`** method takes three arguments, the first argument, *startAngle*, represents the angle in radians at which the gradient begins, and the last two arguments, (*x*, *y*), represent the center of the gradient in CSS pixels. The method, when invoked, must return a conic `CanvasGradient`[p670] initialized with the specified center and angle.

It follows the same rendering rule as CSS 'conic-gradient' and it is equivalent to CSS 'conic-gradient(from *adjustedStartAngle*rad at *x*px *y*px, *angularColorStopList*)'. Here:

- *adjustedStartAngle* is given by *startAngle* + π/2;
- *angularColorStopList* is given by the color stops that have been added to the `CanvasGradient`[p670] using `addColorStop()`[p698], with the color stop offsets interpreted as percentages.

Gradients must be painted only where the relevant stroking or filling effects requires that they be drawn.

Patterns are represented by objects implementing the opaque `CanvasPattern`[p670] interface.

For web developers (non-normative)

pattern = context.**`createPattern`**[p699]**(*image, repetition*)**

Returns a `CanvasPattern`[p670] object that uses the given image and repeats in the direction(s) given by the *repetition* argument.

The allowed values for *repetition* are `repeat` (both directions), `repeat-x` (horizontal only), `repeat-y` (vertical only), and `no-repeat` (neither). If the *repetition* argument is empty, the value `repeat` is used.

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an `"InvalidStateError"` `DOMException`.

pattern.**`setTransform`**[p699]**(*transform*)**

Sets the transformation matrix that will be used when rendering the pattern during a fill or stroke painting operation.

The **`createPattern(image, repetition)`** method, when invoked, must run these steps:

1. Let *usability* be the result of checking the usability of[p695] *image*.
2. If *usability* is *bad*, then return null.
3. Assert: *usability* is *good*.
4. If *repetition* is the empty string, then set it to "`repeat`".
5. If *repetition* is not identical to one of "`repeat`", "`repeat-x`", "`repeat-y`", or "`no-repeat`", then throw a `"SyntaxError"` `DOMException`.
6. Let *pattern* be a new `CanvasPattern`[p670] object with the image *image* and the repetition behavior given by *repetition*.
7. If *image* is not origin-clean[p696], then mark *pattern* as **not origin-clean**.
8. Return *pattern*.

Modifying the *image* used when creating a `CanvasPattern`[p670] object after calling the `createPattern()`[p699] method must not affect the pattern(s) rendered by the `CanvasPattern`[p670] object.

Patterns have a transformation matrix, which controls how the pattern is used when it is painted. Initially, a pattern's transformation matrix must be the identity matrix.

The **`setTransform(transform)`** method, when invoked, must run these steps:

1. Let *matrix* be the result of creating a `DOMMatrix` from the 2D dictionary *transform*.
2. If one or more of *matrix*'s m11 element, m12 element, m21 element, m22 element, m41 element, or m42 element are

infinite or NaN, then return.

3. Reset the pattern's transformation matrix to *matrix*.

When a pattern is to be rendered within an area, the user agent must run the following steps to determine what is rendered:

1. Create an infinite transparent black bitmap.
2. Place a copy of the image on the bitmap, anchored such that its top left corner is at the origin of the coordinate space, with one coordinate space unit per CSS pixel of the image, then place repeated copies of this image horizontally to the left and right, if the repetition behavior is "`repeat-x`", or vertically up and down, if the repetition behavior is "`repeat-y`", or in all four directions all over the bitmap, if the repetition behavior is "`repeat`".

   If the original image data is a bitmap image, then the value painted at a point in the area of the repetitions is computed by filtering the original image data. When scaling up, if the `imageSmoothingEnabled`[p715] attribute is set to false, then the image must be rendered using nearest-neighbor interpolation. Otherwise, the user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). User agents which support multiple filtering algorithms may use the value of the `imageSmoothingQuality`[p715] attribute to guide the choice of filtering algorithm. When such a filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from wrapping the pixel's coordinates to the original image's dimensions. (That is, the filter uses 'repeat' behavior, regardless of the value of the pattern's repetition behavior.)
3. Transform the resulting bitmap according to the pattern's transformation matrix.
4. Transform the resulting bitmap again, this time according to the current transformation matrix[p693].
5. Replace any part of the image outside the area in which the pattern is to be rendered with transparent black.
6. The resulting bitmap is what is to be rendered, with the same origin and same scale.

If a radial gradient or repeated pattern is used when the transformation matrix is singular, then the resulting style must be transparent black (otherwise the gradient or pattern would be collapsed to a point or line, leaving the other pixels undefined). Linear gradients and solid colors always define all points even with singular transformation matrices.

4.12.5.1.10 Drawing rectangles to the bitmap §[p700]

Objects that implement the `CanvasRect`[p667] interface provide the following methods for immediately drawing rectangles to the bitmap. The methods each take four arguments; the first two give the *x* and *y* coordinates of the top left of the rectangle, and the second two give the width *w* and height *h* of the rectangle, respectively.

The current transformation matrix[p693] must be applied to the following four coordinates, which form the path that must then be closed to get the specified rectangle: (*x*, *y*), (*x*+*w*, *y*), (*x*+*w*, *y*+*h*), (*x*, *y*+*h*).

Shapes are painted without affecting the current default path[p703], and are subject to the clipping region[p704], and, with the exception of `clearRect()`[p700], also shadow effects[p716], global alpha[p715], and the current compositing and blending operator[p715].

For web developers (non-normative)

***context*.clearRect**[p700]**(*x*, *y*, *w*, *h*)**

Clears all pixels on the bitmap in the given rectangle to transparent black.

***context*.fillRect**[p701]**(*x*, *y*, *w*, *h*)**

Paints the given rectangle onto the bitmap, using the current fill style.

***context*.strokeRect**[p701]**(*x*, *y*, *w*, *h*)**

Paints the box that outlines the given rectangle onto the bitmap, using the current stroke style.

The **`clearRect(x, y, w, h)`** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Let *pixels* be the set of pixels in the specified rectangle that also intersect the current clipping region[p704].
3. Clear the pixels in *pixels* to a transparent black, erasing any previous image.

Note

If either height or width are zero, this method has no effect, since the set of pixels would be empty.

The **fillRect(*x*, *y*, *w*, *h*)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. If either *w* or *h* are zero, then return.
3. Paint the specified rectangular area using this's fill style[p696].

The **strokeRect(*x*, *y*, *w*, *h*)** method, when invoked, must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Take the result of tracing the path[p676] described below, using the CanvasPathDrawingStyles[p669] interface's line styles, and fill it with this's stroke style[p696].

If both *w* and *h* are zero, the path has a single subpath with just one point (*x*, *y*), and no lines, and this method thus has no effect (the trace a path[p676] algorithm returns an empty path in that case).

If just one of either *w* or *h* is zero, then the path has a single subpath consisting of two points, with coordinates (*x*, *y*) and (*x*+*w*, *y*+*h*), in that order, connected by a single straight line.

Otherwise, the path has a single subpath consisting of four points, with coordinates (*x*, *y*), (*x*+*w*, *y*), (*x*+*w*, *y*+*h*), and (*x*, *y*+*h*), connected to each other in that order by straight lines.

MDN

4.12.5.1.11 Drawing text to the bitmap §[p701]

For web developers (non-normative)

***context*.fillText[p701](*text*, *x*, *y* [, *maxWidth*])**

***context*.strokeText[p701](*text*, *x*, *y* [, *maxWidth*])**

Fills or strokes (respectively) the given text at the given position. If a maximum width is provided, the text will be scaled to fit that width if necessary.

***metrics* = *context*.measureText[p702](*text*)**

Returns a TextMetrics[p670] object with the metrics of the given text in the current font.

***metrics*.width[p702]**

***metrics*.actualBoundingBoxLeft[p702]**

***metrics*.actualBoundingBoxRight[p702]**

***metrics*.fontBoundingBoxAscent[p702]**

***metrics*.fontBoundingBoxDescent[p702]**

***metrics*.actualBoundingBoxAscent[p702]**

***metrics*.actualBoundingBoxDescent[p702]**

***metrics*.emHeightAscent[p703]**

***metrics*.emHeightDescent[p703]**

***metrics*.hangingBaseline[p703]**

***metrics*.alphabeticBaseline[p703]**

***metrics*.ideographicBaseline[p703]**

Returns the measurement described below.

Objects that implement the CanvasText[p668] interface provide the following methods for rendering text.

The **fillText(*text*, *x*, *y*, *maxWidth*)** and **strokeText(*text*, *x*, *y*, *maxWidth*)** methods render the given *text* at the given (*x*, *y*) coordinates ensuring that the text isn't wider than *maxWidth* if specified, using the current font[p680], textAlign[p681], and textBaseline[p681] values. Specifically, when the methods are invoked, the user agent must run these steps:

1. If any of the arguments are infinite or NaN, then return.

2. Run the text preparation algorithm[p684], passing it *text*, the object implementing the `CanvasText`[p668] interface, and, if the *maxWidth* argument was provided, that argument. Let *glyphs* be the result.

3. Move all the shapes in *glyphs* to the right by *x* CSS pixels and down by *y* CSS pixels.

4. Paint the shapes given in *glyphs*, as transformed by the current transformation matrix[p693], with each CSS pixel in the coordinate space of *glyphs* mapped to one coordinate space unit.

   For `fillText()`[p701], this's fill style[p696] must be applied to the shapes and this's stroke style[p696] must be ignored. For `strokeText()`[p701], the reverse holds: this's stroke style[p696] must be applied to the result of tracing[p676] the shapes using the object implementing the `CanvasText`[p668] interface for the line styles, and this's fill style[p696] must be ignored.

   These shapes are painted without affecting the current path, and are subject to shadow effects[p716], global alpha[p715], the clipping region[p704], and the current compositing and blending operator[p715].

The **`measureText(text)`** method steps are to run the text preparation algorithm[p684], passing it *text* and the object implementing the `CanvasText`[p668] interface, and then using the returned inline box must return a new `TextMetrics`[p670] object with members behaving as described in the following list: [CSS][p1411]

`width` attribute

The width of that inline box, in CSS pixels. (The text's advance width.)

`actualBoundingBoxLeft` attribute

The distance parallel to the baseline from the alignment point given by the `textAlign`[p681] attribute to the left side of the bounding rectangle of the given text, in CSS pixels; positive numbers indicating a distance going left from the given alignment point.

Note

The sum of this value and the next (`actualBoundingBoxRight`[p702]) can be wider than the width of the inline box (`width`[p702]), in particular with slanted fonts where characters overhang their advance width.

`actualBoundingBoxRight` attribute

The distance parallel to the baseline from the alignment point given by the `textAlign`[p681] attribute to the right side of the bounding rectangle of the given text, in CSS pixels; positive numbers indicating a distance going right from the given alignment point.

`fontBoundingBoxAscent` attribute

The distance from the horizontal line indicated by the `textBaseline`[p681] attribute to the ascent metric of the first available font, in CSS pixels; positive numbers indicating a distance going up from the given baseline.

Note

This value and the next are useful when rendering a background that have to have a consistent height even if the exact text being rendered changes. The `actualBoundingBoxAscent`[p702] attribute (and its corresponding attribute for the descent) are useful when drawing a bounding box around specific text.

`fontBoundingBoxDescent` attribute

The distance from the horizontal line indicated by the `textBaseline`[p681] attribute to the descent metric of the first available font, in CSS pixels; positive numbers indicating a distance going down from the given baseline.

`actualBoundingBoxAscent` attribute

The distance from the horizontal line indicated by the `textBaseline`[p681] attribute to the top of the bounding rectangle of the given text, in CSS pixels; positive numbers indicating a distance going up from the given baseline.

Note

This number can vary greatly based on the input text, even if the first font specified covers all the characters in the input. For example, the `actualBoundingBoxAscent`[p702] of a lowercase "o" from an alphabetic baseline would be less than that of an uppercase "F". The value can easily be negative; for example, the distance from the top of the em box (`textBaseline`[p681] value "`top`[p682]") to the top of the bounding rectangle when the given text is just a single comma "," would likely (unless the font is quite unusual) be negative.

`actualBoundingBoxDescent` attribute

The distance from the horizontal line indicated by the `textBaseline`[p681] attribute to the bottom of the bounding rectangle of the given text, in CSS pixels; positive numbers indicating a distance going down from the given baseline.

emHeightAscent attribute

The distance from the horizontal line indicated by the textBaseline[p681] attribute to the highest top of the em squares in the inline box, in CSS pixels; positive numbers indicating that the given baseline is below the top of that em square (so this value will usually be positive). Zero if the given baseline is the top of that em square; half the font size if the given baseline is the middle of that em square.

emHeightDescent attribute

The distance from the horizontal line indicated by the textBaseline[p681] attribute to the lowest bottom of the em squares in the inline box, in CSS pixels; positive numbers indicating that the given baseline is above the bottom of that em square. (Zero if the given baseline is the bottom of that em square.)

hangingBaseline attribute

The distance from the horizontal line indicated by the textBaseline[p681] attribute to the hanging baseline of the inline box, in CSS pixels; positive numbers indicating that the given baseline is below the hanging baseline. (Zero if the given baseline is the hanging baseline.)

alphabeticBaseline attribute

The distance from the horizontal line indicated by the textBaseline[p681] attribute to the alphabetic baseline of the inline box, in CSS pixels; positive numbers indicating that the given baseline is below the alphabetic baseline. (Zero if the given baseline is the alphabetic baseline.)

ideographicBaseline attribute

The distance from the horizontal line indicated by the textBaseline[p681] attribute to the ideographic-under baseline of the inline box, in CSS pixels; positive numbers indicating that the given baseline is below the ideographic-under baseline. (Zero if the given baseline is the ideographic-under baseline.)

Note

Glyphs rendered using fillText()[p701] and strokeText()[p701] can spill out of the box given by the font size (the em square size) and the width returned by measureText()[p702] (the text width). Authors are encouraged to use the bounding box values described above if this is an issue.

Note

A future version of the 2D context API might provide a way to render fragments of documents, rendered using CSS, straight to the canvas. This would be provided in preference to a dedicated way of doing multiline layout.

4.12.5.1.12 Drawing paths to the canvas §[p703]

Objects that implement the CanvasDrawPath[p668] interface have a **current default path**. There is only one current default path[p703], it is not part of the drawing state[p674]. The current default path[p703] is a path[p686], as described above.

For web developers (non-normative)

***context*.beginPath[p704]()**

Resets the current default path[p703].

***context*.fill[p704]([*fillRule*])**

***context*.fill[p704](*path* [, *fillRule*])**

Fills the subpaths of the current default path[p703] or the given path with the current fill style, obeying the given fill rule.

***context*.stroke[p704]()**

***context*.stroke[p704](*path*)**

Strokes the subpaths of the current default path[p703] or the given path with the current stroke style.

***context*.clip[p704]([*fillRule*])**

***context*.clip[p704](*path* [, *fillRule*])**

Further constrains the clipping region to the current default path[p703] or the given path, using the given fill rule to determine what points are in the path.

***context*.isPointInPath[p705](*x*, *y* [, *fillRule*])**

***context*.isPointInPath[p705](*path*, *x*, *y* [, *fillRule*])**

Returns true if the given point is in the current default path[p703] or the given path, using the given fill rule to determine what points are in the path.

***context*.isPointInStroke[p705](*x*, *y*)**

***context*.isPointInStroke[p705](*path*, *x*, *y*)**

Returns true if the given point would be in the region covered by the stroke of the current default path[p703] or the given path, given the current stroke style.

The **beginPath()** method steps are to empty the list of subpaths in this's current default path[p703] so that it once again has zero subpaths.

Where the following method definitions use the term **intended path** for a Path2D[p670]-or-null *path*, it means *path* itself if it is a Path2D[p670] object, or the current default path[p703] otherwise.

When the intended path[p704] is a Path2D[p670] object, the coordinates and lines of its subpaths must be transformed according to the current transformation matrix[p693] on the object implementing the CanvasTransform[p667] interface when used by these methods (without affecting the Path2D[p670] object itself). When the intended path is the current default path[p703], it is not affected by the transform. (This is because transformations already affect the current default path[p703] when it is constructed, so applying it when it is painted as well would result in a double transformation.)

The **fill(*fillRule*)** method steps are to run the fill steps[p704] given this, null, and *fillRule*.

The **fill(*path*, *fillRule*)** method steps are to run the fill steps[p704] given this, *path*, and *fillRule*.

The **fill steps**, given a CanvasDrawPath[p668] *context*, a Path2D[p670]-or-null *path*, and a fill rule[p673] *fillRule*, are to fill all the subpaths of the intended path[p704] for *path*, using *context*'s fill style[p696], and using the fill rule[p673] indicated by *fillRule*. Open subpaths must be implicitly closed when being filled (without affecting the actual subpaths).

The **stroke()** method steps are to run the stroke steps[p704] given this and null.

The **stroke(*path*)** method steps are to run the stroke steps[p704] given this and *path*.

The **stroke steps**, given a CanvasDrawPath[p668] *context* and a Path2D[p670]-or-null *path*, are to trace[p676] the intended path[p704] for *path*, using *context*'s line styles as set by its CanvasPathDrawingStyles[p669] mixin, and then fill the resulting path using *context*'s stroke style[p696], using the nonzero winding rule[p673].

Note

As a result of how the algorithm to trace a path[p676] is defined, overlapping parts of the paths in one stroke operation are treated as if their union was what was painted.

Note

The stroke style is affected by the transformation during painting, even if the current default path[p703] is used.

Paths, when filled or stroked, must be painted without affecting the current default path[p703] or any Path2D[p670] objects, and must be subject to shadow effects[p716], global alpha[p715], the clipping region[p704], and the current compositing and blending operator[p715]. (The effect of transformations is described above and varies based on which path is being used.)

The **clip(*fillRule*)** method steps are to run the clip steps[p704] given this, null, and *fillRule*.

The **clip(*path*, *fillRule*)** method steps are to run the clip steps[p704] given this, *path*, and *fillRule*.

The **clip steps**, given a CanvasDrawPath[p668] *context*, a Path2D[p670]-or-null *path*, and a fill rule[p673] *fillRule*, are to create a new **clipping region** by calculating the intersection of *context*'s current clipping region and the area described by the intended path[p704] for *path*, using the fill rule[p673] indicated by *fillRule*. Open subpaths must be implicitly closed when computing the clipping region, without affecting the actual subpaths. The new clipping region replaces the current clipping region.

When the context is initialized, its current clipping region must be set to the largest infinite surface (i.e. by default, no clipping occurs).

The **isPointInPath(*x*, *y*, *fillRule*)** method steps are to return the result of the is point in path steps[p705] given this, null, *x*, *y*, and *fillRule*.

The **isPointInPath(*path*, *x*, *y*, *fillRule*)** method steps are to return the result of the is point in path steps[p705] given this, null, *x*, *y*, and *fillRule*.

The **is point in path steps**, given a CanvasDrawPath[p668] *context*, a Path2D[p670]-or-null *path*, two numbers *x* and *y*, and a fill rule[p673] *fillRule*, are:

1. If *x* or *y* are infinite or NaN, then return false.
2. If the point given by the *x* and *y* coordinates, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the intended path[p704] for *path* as determined by the fill rule[p673] indicated by *fillRule*, then return true. Open subpaths must be implicitly closed when computing the area inside the path, without affecting the actual subpaths. Points on the path itself must be considered to be inside the path.
3. Return false.

The **isPointInStroke(*x*, *y*)** method steps are to return the result of the is point in stroke steps[p705] given this, null, *x*, and *y*.

The **isPointInStroke(*path*, *x*, *y*)** method steps are to return the result of the is point in stroke steps[p705] given this, *path*, *x*, and *y*.

The **is point in stroke steps**, given a CanvasDrawPath[p668] *context*, a Path2D[p670]-or-null *path*, and two numbers *x* and *y*, are:

1. If *x* or *y* are infinite or NaN, then return false.
2. If the point given by the *x* and *y* coordinates, when treated as coordinates in the canvas coordinate space unaffected by the current transformation, is inside the path that results from tracing[p676] the intended path[p704] for *path*, using the nonzero winding rule[p673], and using *context*'s line styles as set by its CanvasPathDrawingStyles[p669] mixin, then return true. Points on the resulting path must be considered to be inside the path.
3. Return false.

Example

This canvas[p661] element has a couple of checkboxes. The path-related commands are highlighted:

```
<canvas height=400 width=750>
 <label><input type=checkbox id=showA> Show As</label>
 <label><input type=checkbox id=showB> Show Bs</label>
 <!-- ... -->
</canvas>
<script>
 function drawCheckbox(context, element, x, y, paint) {
   context.save();
   context.font = '10px sans-serif';
   context.textAlign = 'left';
   context.textBaseline = 'middle';
   var metrics = context.measureText(element.labels[0].textContent);
   if (paint) {
     context.beginPath();
     context.strokeStyle = 'black';
     context.rect(x-5, y-5, 10, 10);
     context.stroke();
     if (element.checked) {
       context.fillStyle = 'black';
       context.fill();
     }
     context.fillText(element.labels[0].textContent, x+5, y);
   }
   context.beginPath();
   context.rect(x-7, y-7, 12 + metrics.width+2, 14);
```

```
    context.drawFocusIfNeeded(element);
    context.restore();
  }
  function drawBase() { /* ... */ }
  function drawAs() { /* ... */ }
  function drawBs() { /* ... */ }
  function redraw() {
    var canvas = document.getElementsByTagName('canvas')[0];
    var context = canvas.getContext('2d');
    context.clearRect(0, 0, canvas.width, canvas.height);
    drawCheckbox(context, document.getElementById('showA'), 20, 40, true);
    drawCheckbox(context, document.getElementById('showB'), 20, 60, true);
    drawBase();
    if (document.getElementById('showA').checked)
      drawAs();
    if (document.getElementById('showB').checked)
      drawBs();
  }
  function processClick(event) {
    var canvas = document.getElementsByTagName('canvas')[0];
    var context = canvas.getContext('2d');
    var x = event.clientX;
    var y = event.clientY;
    var node = event.target;
    while (node) {
      x -= node.offsetLeft - node.scrollLeft;
      y -= node.offsetTop - node.scrollTop;
      node = node.offsetParent;
    }
    drawCheckbox(context, document.getElementById('showA'), 20, 40, false);
    if (context.isPointInPath(x, y))
      document.getElementById('showA').checked = !(document.getElementById('showA').checked);
    drawCheckbox(context, document.getElementById('showB'), 20, 60, false);
    if (context.isPointInPath(x, y))
      document.getElementById('showB').checked = !(document.getElementById('showB').checked);
    redraw();
  }
  document.getElementsByTagName('canvas')[0].addEventListener('focus', redraw, true);
  document.getElementsByTagName('canvas')[0].addEventListener('blur', redraw, true);
  document.getElementsByTagName('canvas')[0].addEventListener('change', redraw, true);
  document.getElementsByTagName('canvas')[0].addEventListener('click', processClick, false);
  redraw();
</script>
```

4.12.5.1.13 Drawing focus rings and scrolling paths into view §[p706]

For web developers (non-normative)

***context*.drawFocusIfNeeded[p707](*element*)**

***context*.drawFocusIfNeeded[p707](*path*, *element*)**

If the given element is focused[p817], draws a focus ring around the current default path[p703] or the given path, following the platform conventions for focus rings.

***context*.scrollPathIntoView[p707]()**

***context*.scrollPathIntoView[p707](*path*)**

Scrolls the current default path[p703] or the given path into view. This is especially useful on devices with small screens, where the whole canvas might not be visible at once.

Objects that implement the CanvasUserInterface[p668] interface provide the following methods to control drawing focus rings and scrolling paths into view.

The **drawFocusIfNeeded(*element*)** method, when invoked, must run these steps:

1. If *element* is not focused[p817] or is not a descendant of the element with whose context the method is associated, then return.
2. Draw a focus ring of the appropriate style along the intended path, following platform conventions.

   Note

   Some platforms only draw focus rings around elements that have been focused from the keyboard, and not those focused from the mouse. Other platforms simply don't draw focus rings around some elements at all unless relevant accessibility features are enabled. This API is intended to follow these conventions. User agents that implement distinctions based on the manner in which the element was focused are encouraged to classify focus driven by the focus()[p828] method based on the kind of user interaction event from which the call was triggered (if any).

   The focus ring should not be subject to the shadow effects[p716], the global alpha[p715], the current compositing and blending operator[p715], the fill style[p696], the stroke style[p696], or any of the members in the CanvasPathDrawingStyles[p669], CanvasTextDrawingStyles[p669] interfaces, but *should* be subject to the clipping region[p704]. (The effect of transformations is described above and varies based on which path is being used.)
3. Inform the user[p707] that the focus is at the location given by the intended path. User agents may wait until the next time the event loop[p1071] reaches its update the rendering[p1074] step to optionally inform the user.

User agents should not implicitly close open subpaths in the intended path when drawing the focus ring.

Note

This might be a moot point, however. For example, if the focus ring is drawn as an axis-aligned bounding rectangle around the points in the intended path, then whether the subpaths are closed or not has no effect. This specification intentionally does not specify precisely how focus rings are to be drawn: user agents are expected to honor their platform's native conventions.

The **scrollPathIntoView()** method, when invoked, must run these steps:

1. Let *specifiedRectangle* be the rectangle of the bounding box of the intended path.
2. Let *notionalChild* be a hypothetical element that is a rendered child of the canvas[p661] element whose dimensions are those of *specifiedRectangle*.
3. Scroll *notionalChild* into view with *behavior* set to "auto", *block* set to "start", and *inline* set to "nearest".
4. Optionally, inform the user[p707] that the caret or selection (or both) cover *specifiedRectangle* of the canvas. The user agent may wait until the next time the event loop[p1071] reaches its update the rendering[p1074] step to optionally inform the user.

"Inform the user", as used in this section, does not imply any persistent state change. It could mean, for instance, calling a system accessibility API to notify assistive technologies such as magnification tools so that the user's magnifier moves to the given area of the canvas. However, it does not associate the path with the element, or provide a region for tactile feedback, etc.

4.12.5.1.14 Drawing images §[p707]

Objects that implement the CanvasDrawImage[p668] interface have the **drawImage()** method to draw images.

This method can be invoked with three different sets of arguments:

- `drawImage(image, dx, dy)`
- `drawImage(image, dx, dy, dw, dh)`
- `drawImage(image, sx, sy, sw, sh, dx, dy, dw, dh)`

For web developers (non-normative)

***context*.drawImage[p707](*image*, *dx*, *dy*)**
***context*.drawImage[p707](*image*, *dx*, *dy*, *dw*, *dh*)**
***context*.drawImage[p707](*image*, *sx*, *sy*, *sw*, *sh*, *dx*, *dy*, *dw*, *dh*)**

Draws the given image onto the canvas. The arguments are interpreted as follows:

If the image isn't yet fully decoded, then nothing is drawn. If the image is a canvas with no data, throws an "InvalidStateError" DOMException.

When the drawImage()[p707] method is invoked, the user agent must run these steps:

1. If any of the arguments are infinite or NaN, then return.
2. Let *usability* be the result of checking the usability of *image*[p695].
3. If *usability* is *bad*, then return (without drawing anything).
4. Establish the source and destination rectangles as follows:

   If not specified, the *dw* and *dh* arguments must default to the values of *sw* and *sh*, interpreted such that one CSS pixel in the image is treated as one unit in the output bitmap[p671]'s coordinate space. If the *sx*, *sy*, *sw*, and *sh* arguments are omitted, then they must default to 0, 0, the image's natural width in image pixels, and the image's natural height in image pixels, respectively. If the image has no natural dimensions, then the *concrete object size* must be used instead, as determined using the CSS "Concrete Object Size Resolution" algorithm, with the *specified size* having neither a definite width nor height, nor any additional constraints, the object's natural properties being those of the *image* argument, and the default object size being the size of the output bitmap[p671]. [CSSIMAGES][p1411]

   The source rectangle is the rectangle whose corners are the four points (*sx*, *sy*), (*sx*+*sw*, *sy*), (*sx*+*sw*, *sy*+*sh*), (*sx*, *sy*+*sh*).

   The destination rectangle is the rectangle whose corners are the four points (*dx*, *dy*), (*dx*+*dw*, *dy*), (*dx*+*dw*, *dy*+*dh*), (*dx*, *dy*+*dh*).

   When the source rectangle is outside the source image, the source rectangle must be clipped to the source image and the destination rectangle must be clipped in the same proportion.

   Note

   When the destination rectangle is outside the destination image (the output bitmap[p671]), the pixels that land outside the output bitmap[p671] are discarded, as if the destination was an infinite canvas whose rendering was clipped to the dimensions of the output bitmap[p671].

5. If one of the *sw* or *sh* arguments is zero, then return. Nothing is painted.

6. Paint the region of the *image* argument specified by the source rectangle on the region of the rendering context's output bitmap[p671] specified by the destination rectangle, after applying the current transformation matrix[p693] to the destination rectangle.

   The image data must be processed in the original direction, even if the dimensions given are negative.

   When scaling up, if the `imageSmoothingEnabled`[p715] attribute is set to true, the user agent should attempt to apply a smoothing algorithm to the image data when it is scaled. User agents which support multiple filtering algorithms may use the value of the `imageSmoothingQuality`[p715] attribute to guide the choice of filtering algorithm when the `imageSmoothingEnabled`[p715] attribute is set to true. Otherwise, the image must be rendered using nearest-neighbor interpolation.

   Note

   This specification does not define the precise algorithm to use when scaling an image down, or when scaling an image up when the `imageSmoothingEnabled`[p715] attribute is set to true.

   Note

   When a `canvas`[p661] element is drawn onto itself, the drawing model[p718] requires the source to be copied before the image is drawn, so it is possible to copy parts of a `canvas`[p661] element onto overlapping parts of itself.

   If the original image data is a bitmap image, then the value painted at a point in the destination rectangle is computed by filtering the original image data. The user agent may use any filtering algorithm (for example bilinear interpolation or nearest-neighbor). When the filtering algorithm requires a pixel value from outside the original image data, it must instead use the value from the nearest edge pixel. (That is, the filter uses 'clamp-to-edge' behavior.) When the filtering algorithm requires a pixel value from outside the source rectangle but inside the original image data, then the value from the original image data must be used.

   Note

   Thus, scaling an image in parts or in whole will have the same effect. This does mean that when sprites coming from a single sprite sheet are to be scaled, adjacent images in the sprite sheet can interfere. This can be avoided by ensuring each sprite in the sheet is surrounded by a border of transparent black, or by copying sprites to be scaled into temporary `canvas`[p661] elements and drawing the scaled sprites from there.

   Images are painted without affecting the current path, and are subject to shadow effects[p716], global alpha[p715], the clipping region[p704], and the current compositing and blending operator[p715].

7. If *image* is not origin-clean[p696], then set the `CanvasRenderingContext2D`[p666]'s origin-clean[p663] flag to false.

4.12.5.1.15 Pixel manipulation §[p709]

For web developers (non-normative)

***imagedata* = new ImageData[p710](*sw*, *sh* [, *settings*])**

Returns an `ImageData`[p670] object with the given dimensions and the color space indicated by *settings*. All the pixels in the returned object are transparent black.

Throws an `"IndexSizeError"` `DOMException` if either of the width or height arguments are zero.

***imagedata* = new ImageData[p710](*data*, *sw* [, *sh* [, *settings*]])**

Returns an `ImageData`[p670] object using the data provided in the `Uint8ClampedArray` argument, interpreted using the given dimensions and the color space indicated by *settings*.

As each pixel in the data is represented by four numbers, the length of the data needs to be a multiple of four times the given width. If the height is provided as well, then the length needs to be exactly the width times the height times 4.

Throws an `"IndexSizeError"` `DOMException` if the given data and dimensions can't be interpreted consistently, or if either dimension is zero.

***imagedata* = *context*.createImageData[p711](*imagedata*)**

Returns an `ImageData`[p670] object with the same dimensions and color space as the argument. All the pixels in the returned object are transparent black.

***imagedata* = *context*.createImageData[p710](*sw*, *sh* [, *settings*])**

Returns an ImageData[p670] object with the given dimensions. The color space of the returned object is the color space[p672] of *context* unless overridden by *settings*. All the pixels in the returned object are transparent black.

Throws an "IndexSizeError" DOMException if either of the width or height arguments are zero.

***imagedata* = *context*.getImageData[p711](*sx*, *sy*, *sw*, *sh* [, *settings*])**

Returns an ImageData[p670] object containing the image data for the given rectangle of the bitmap. The color space of the returned object is the color space[p672] of *context* unless overridden by *settings*.

Throws an "IndexSizeError" DOMException if the either of the width or height arguments are zero.

***imagedata*.width[p711]**

***imagedata*.height[p711]**

Returns the actual dimensions of the data in the ImageData[p670] object, in pixels.

***imagedata*.data[p711]**

Returns the one-dimensional array containing the data in RGBA order, as integers in the range 0 to 255.

***imagedata*.colorSpace[p711]**

Returns the color space of the pixels.

***context*.putImageData[p712](*imagedata*, *dx*, *dy* [, *dirtyX*, *dirtyY*, *dirtyWidth*, *dirtyHeight*])**

Paints the data from the given ImageData[p670] object onto the bitmap. If a dirty rectangle is provided, only the pixels from that rectangle are painted.

The globalAlpha[p715] and globalCompositeOperation[p715] properties, as well as the shadow attributes[p716], are ignored for the purposes of this method call; pixels in the canvas are replaced wholesale, with no composition, alpha blending, no shadows, etc.

Throws an "InvalidStateError" DOMException if the *imagedata* object's data[p711] attribute value's [[ViewedArrayBuffer]] internal slot is detached.

Objects that implement the CanvasImageData[p668] interface provide the following methods for reading and writing pixel data to the bitmap.

The **new ImageData(*sw*, *sh*, *settings*)** constructor steps are:

1. If one or both of *sw* and *sh* are zero, then throw an "IndexSizeError" DOMException.
2. Initialize[p711] this given *sw*, *sh*, and *settings*[p711] set to *settings*.
3. Initialize the image data of this to transparent black.

The **new ImageData(*data*, *sw*, *sh*, *settings*)** constructor steps are:

1. Let *length* be the number of bytes in *data*.
2. If *length* is not a nonzero integral multiple of four, then throw an "InvalidStateError" DOMException.
3. Let *length* be *length* divided by four.
4. If *length* is not an integral multiple of *sw*, then throw an "IndexSizeError" DOMException.

   Note

   At this step, the length is guaranteed to be greater than zero (otherwise the second step above would have aborted the steps), so if sw *is zero, this step will throw the exception and return.*

5. Let *height* be *length* divided by *sw*.
6. If *sh* was given and its value is not equal to *height*, then throw an "IndexSizeError" DOMException.
7. Initialize[p711] this given *sw*, *sh*, *settings*[p711] set to *settings*, and *source*[p711] set to *data*.

   Note

   This step does not set this's data to a copy of data*. It sets it to the actual* Uint8ClampedArray *object passed as* data*.*

The **createImageData(*sw*, *sh*, *settings*)** method steps are:

1. If one or both of *sw* and *sh* are zero, then throw an "IndexSizeError" DOMException.
2. Let *newImageData* be a new ImageData[p670] object.
3. Initialize[p711] *newImageData* given the absolute magnitude of *sw*, the absolute magnitude of *sh*, *settings*[p711] set to *settings*, and *defaultColorSpace*[p711] set to this's color space[p672].
4. Initialize the image data of *newImageData* to transparent black.
5. Return *newImageData*.

The **createImageData(*imagedata*)** method steps are:

1. Let *newImageData* be a new ImageData[p670] object.
2. Initialize[p711] *newImageData* given the value of *imagedata*'s width[p711] attribute, the value of *imagedata*'s height[p711] attribute, and *defaultColorSpace*[p711] set to the value of *imagedata*'s colorSpace[p711] attribute.
3. Initialize the image data of *newImageData* to transparent black.
4. Return *newImageData*.

The **getImageData(*sx, sy, sw, sh, settings*)** method steps are:

1. If either the *sw* or *sh* arguments are zero, then throw an "IndexSizeError" DOMException.
2. If the CanvasRenderingContext2D[p666]'s origin-clean[p663] flag is set to false, then throw a "SecurityError" DOMException.
3. Let *imageData* be a new ImageData[p670] object.
4. Initialize[p711] *imageData* given *sw*, *sh*, *settings*[p711] set to *settings*, and *defaultColorSpace*[p711] set to this's color space[p672].
5. Let the source rectangle be the rectangle whose corners are the four points (*sx*, *sy*), (*sx*+*sw*, *sy*), (*sx*+*sw*, *sy*+*sh*), (*sx*, *sy*+*sh*).
6. Set the pixel values of *imageData* to be the pixels of this's output bitmap[p671] in the area specified by the source rectangle in the bitmap's coordinate space units, converted from this's color space[p672] to *imageData*'s colorSpace[p711] using 'relative-colorimetric' rendering intent.
7. Set the pixels values of *imageData* for areas of the source rectangle that are outside of the output bitmap[p671] to transparent black.
8. Return *imageData*.

To **initialize an ImageData object** *imageData*, given a positive integer number of rows *rows*, a positive integer number of pixels per row *pixelsPerRow*, an optional ImageDataSettings[p670] ***settings***, an optional Uint8ClampedArray ***source***, and an optional PredefinedColorSpace[p666] ***defaultColorSpace***:

1. If *source* was given, then initialize the **data** attribute of *imageData* to *source*.
2. Otherwise (*source* was not given), initialize the data[p711] attribute of *imageData* to a new Uint8ClampedArray object. The Uint8ClampedArray object must use a new Canvas Pixel ArrayBuffer[p712] for its storage, and must have a zero start offset and a length equal to the length of its storage, in bytes. The Canvas Pixel ArrayBuffer[p712] must have the correct size to store *rows* × *pixelsPerRow* pixels.

   If the Canvas Pixel ArrayBuffer[p712] cannot be allocated, then rethrow the RangeError thrown by JavaScript, and return.
3. Initialize the **width** attribute of *imageData* to *pixelsPerRow*.
4. Initialize the **height** attribute of *imageData* to *rows*.
5. If *settings* was given and *settings*["colorSpace[p711]"] exists, then initialize the **colorSpace** attribute of *imageData* to *settings*["**colorSpace**"].
6. Otherwise, if *defaultColorSpace* was given, then initialize the colorSpace[p711] attribute of *imageData* to *defaultColorSpace*.
7. Otherwise, initialize the colorSpace[p711] attribute of *imageData* to "srgb[p673]".

ImageData[p670] objects are serializable objects[p114]. Their serialization steps[p114], given *value* and *serialized*, are:

1. Set *serialized*.[[Data]] to the sub-serialization[p119] of the value of *value*'s `data`[p711] attribute.
2. Set *serialized*.[[Width]] to the value of *value*'s `width`[p711] attribute.
3. Set *serialized*.[[Height]] to the value of *value*'s `height`[p711] attribute.
4. Set *serialized*.[[ColorSpace]] to the value of *value*'s `colorSpace`[p711] attribute.

Their deserialization steps[p114], given *serialized*, *value*, and *targetRealm*, are:

1. Initialize *value*'s `data`[p711] attribute to the sub-deserialization[p123] of *serialized*.[[Data]].
2. Initialize *value*'s `width`[p711] attribute to *serialized*.[[Width]].
3. Initialize *value*'s `height`[p711] attribute to *serialized*.[[Height]].
4. Initialize *value*'s `colorSpace`[p711] attribute to *serialized*.[[ColorSpace]].

A **Canvas Pixel `ArrayBuffer`** is an `ArrayBuffer` whose data is represented in left-to-right order, row by row top to bottom, starting with the top left, with each pixel's red, green, blue, and alpha components being given in that order for each pixel. Each component of each pixel represented in this array must be in the range 0..255, representing the 8 bit value for that component. The components must be assigned consecutive indices starting with 0 for the top left pixel's red component.

The **`putImageData()`** method writes data from `ImageData`[p670] structures back to the rendering context's output bitmap[p671]. Its arguments are: *imagedata*, *dx*, *dy*, *dirtyX*, *dirtyY*, *dirtyWidth*, and *dirtyHeight*.

When the last four arguments to this method are omitted, they must be assumed to have the values 0, 0, the `width`[p711] member of the *imagedata* structure, and the `height`[p711] member of the *imagedata* structure, respectively.

The method, when invoked, must act as follows:

1. Let *buffer* be *imagedata*'s `data`[p711] attribute value's [[ViewedArrayBuffer]] internal slot.
2. If IsDetachedBuffer(*buffer*) is true, then throw an `"InvalidStateError" DOMException`.
3. If *dirtyWidth* is negative, then let *dirtyX* be *dirtyX*+*dirtyWidth*, and let *dirtyWidth* be equal to the absolute magnitude of *dirtyWidth*.

   If *dirtyHeight* is negative, then let *dirtyY* be *dirtyY*+*dirtyHeight*, and let *dirtyHeight* be equal to the absolute magnitude of *dirtyHeight*.
4. If *dirtyX* is negative, then let *dirtyWidth* be *dirtyWidth*+*dirtyX*, and let *dirtyX* be zero.

   If *dirtyY* is negative, then let *dirtyHeight* be *dirtyHeight*+*dirtyY*, and let *dirtyY* be zero.
5. If *dirtyX*+*dirtyWidth* is greater than the `width`[p711] attribute of the *imagedata* argument, then let *dirtyWidth* be the value of that `width`[p711] attribute, minus the value of *dirtyX*.

   If *dirtyY*+*dirtyHeight* is greater than the `height`[p711] attribute of the *imagedata* argument, then let *dirtyHeight* be the value of that `height`[p711] attribute, minus the value of *dirtyY*.
6. If, after those changes, either *dirtyWidth* or *dirtyHeight* are negative or zero, then return without affecting any bitmaps.
7. For all integer values of *x* and *y* where *dirtyX* ≤ *x* < *dirtyX*+*dirtyWidth* and *dirtyY* ≤ *y* < *dirtyY*+*dirtyHeight*, copy the four channels of the pixel with coordinate (*x*, *y*) in the *imagedata* data structure's Canvas Pixel `ArrayBuffer`[p712] to the pixel with coordinate (*dx*+*x*, *dy*+*y*) in the rendering context's output bitmap[p671].

Note

Due to the lossy nature of converting between color spaces and converting to and from premultiplied alpha[p732] color values, pixels that have just been set using `putImageData()`[p712], and are not completely opaque, might be returned to an equivalent `getImageData()`[p711] as different values.

The current path, transformation matrix[p693], shadow attributes[p716], global alpha[p715], the clipping region[p704], and current compositing and blending operator[p715] must not affect the methods described in this section.

Example

In the following example, the script generates an ImageData[p670] object so that it can draw onto it.

```
// canvas is a reference to a <canvas> element
var context = canvas.getContext('2d');

// create a blank slate
var data = context.createImageData(canvas.width, canvas.height);

// create some plasma
FillPlasma(data, 'green'); // green plasma

// add a cloud to the plasma
AddCloud(data, data.width/2, data.height/2); // put a cloud in the middle

// paint the plasma+cloud on the canvas
context.putImageData(data, 0, 0);

// support methods
function FillPlasma(data, color) { ... }
function AddCloud(data, x, y) { ... }
```

Example

Here is an example of using getImageData()[p711] and putImageData()[p712] to implement an edge detection filter.

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <title>Edge detection demo</title>
  <script>
   var image = new Image();
   function init() {
     image.onload = demo;
     image.src = "image.jpeg";
   }
   function demo() {
     var canvas = document.getElementsByTagName('canvas')[0];
     var context = canvas.getContext('2d');

     // draw the image onto the canvas
     context.drawImage(image, 0, 0);

     // get the image data to manipulate
     var input = context.getImageData(0, 0, canvas.width, canvas.height);

     // get an empty slate to put the data into
     var output = context.createImageData(canvas.width, canvas.height);

     // alias some variables for convenience
     // In this case input.width and input.height
     // match canvas.width and canvas.height
     // but we'll use the former to keep the code generic.
     var w = input.width, h = input.height;
     var inputData = input.data;
     var outputData = output.data;

     // edge detection
     for (var y = 1; y < h-1; y += 1) {
       for (var x = 1; x < w-1; x += 1) {
         for (var c = 0; c < 3; c += 1) {
           var i = (y*w + x)*4 + c;
```

```
            outputData[i] = 127 + -inputData[i - w*4 - 4] -   inputData[i - w*4] - inputData[i -
w*4 + 4] +
                                  -inputData[i - 4]       + 8*inputData[i]       - inputData[i + 4]
+
                                  -inputData[i + w*4 - 4] -   inputData[i + w*4] - inputData[i +
w*4 + 4];
          }
          outputData[(y*w + x)*4 + 3] = 255; // alpha
        }
      }

      // put the image data back after manipulation
      context.putImageData(output, 0, 0);
    }
  </script>
 </head>
 <body onload="init()">
  <canvas></canvas>
 </body>
</html>
```

Example

Here is an example of color space conversion applied when drawing a solid color and reading the result back using and getImageData() p711.

```
<!DOCTYPE HTML>
<html lang="en">
<title>Color space image data demo</title>

<canvas></canvas>

<script>
const canvas = document.querySelector('canvas');
const context = canvas.getContext('2d', {colorSpace:'display-p3'});

// Draw a red rectangle. Note that the hex color notation
// specifies sRGB colors.
context.fillStyle = "#FF0000";
context.fillRect(0, 0, 64, 64);

// Get the image data.
const pixels = context.getImageData(0, 0, 1, 1);

// This will print 'display-p3', reflecting the default behavior
// of returning image data in the canvas's color space.
console.log(pixels.colorSpace);

// This will print the values 234, 51, and 35, reflecting the
// red fill color, converted to 'display-p3'.
console.log(pixels.data[0]);
console.log(pixels.data[1]);
console.log(pixels.data[2]);
</script>
```

4.12.5.1.16 Compositing §[p715]

For web developers (non-normative)

***context*.globalAlpha**[p715] **[= *value*]**

Returns the current global alpha[p715] value applied to rendering operations.

Can be set, to change the global alpha[p715] value. Values outside of the range 0.0 .. 1.0 are ignored.

***context*.globalCompositeOperation**[p715] **[= *value*]**

Returns the current compositing and blending operator[p715], from the values defined in *Compositing and Blending*. [COMPOSITE][p1410]

Can be set, to change the current compositing and blending operator[p715]. Unknown values are ignored.

Objects that implement the `CanvasCompositing`[p667] interface have a global alpha[p715] value and a current compositing and blending operator[p715] value that both affect all the drawing operations on this object.

The **global alpha** value gives an alpha value that is applied to shapes and images before they are composited onto the output bitmap[p671]. The value ranges from 0.0 (fully transparent) to 1.0 (no additional transparency). It must initially have the value 1.0.

The **`globalAlpha`** getter steps are to return this's global alpha[p715].

The `globalAlpha`[p715] setter steps are:

1. If the given value is either infinite, NaN, or not in the range 0.0 to 1.0, then return.
2. Otherwise, set this's global alpha[p715] to the given value.

The **current compositing and blending operator** value controls how shapes and images are drawn onto the output bitmap[p671], once they have had the global alpha[p715] and the current transformation matrix[p693] applied. Initially, it must be set to "`source-over`".

The **`globalCompositeOperation`** getter steps are to return this's current compositing and blending operator[p715].

The `globalCompositeOperation`[p715] setter steps are:

1. If the given value is not identical to any of the values that the <blend-mode> or the <composite-mode> properties are defined to take, then return. [COMPOSITE][p1410]
2. Otherwise, set this's current compositing and blending operator[p715] to the given value.

4.12.5.1.17 Image smoothing §[p715]

For web developers (non-normative)

***context*.imageSmoothingEnabled**[p715] **[= *value*]**

Returns whether pattern fills and the `drawImage()`[p707] method will attempt to smooth images if their pixels don't line up exactly with the display, when scaling images up.

Can be set, to change whether images are smoothed (true) or not (false).

***context*.imageSmoothingQuality**[p715] **[= *value*]**

Returns the current image-smoothing-quality preference.

Can be set, to change the preferred quality of image smoothing. The possible values are "`low`[p673]", "`medium`[p673]" and "`high`[p673]". Unknown values are ignored.

Objects that implement the `CanvasImageSmoothing`[p667] interface have attributes that control how image smoothing is performed.

The **`imageSmoothingEnabled`** attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the `CanvasImageSmoothing`[p667] interface is created, the attribute must be set to true.

The **`imageSmoothingQuality`** attribute, on getting, must return the last value it was set to. On setting, it must be set to the new value. When the object implementing the `CanvasImageSmoothing`[p667] interface is created, the attribute must be set to "`low`[p673]".

4.12.5.1.18 Shadows §[p716]

All drawing operations on an object which implements the CanvasShadowStyles[p667] interface are affected by the four global shadow attributes.

For web developers (non-normative)

***context*.shadowColor[p716] [= *value*]**

Returns the current shadow color.

Can be set, to change the shadow color. Values that cannot be parsed as CSS colors are ignored.

***context*.shadowOffsetX[p716] [= *value*]**

***context*.shadowOffsetY[p716] [= *value*]**

Returns the current shadow offset.

Can be set, to change the shadow offset. Values that are not finite numbers are ignored.

***context*.shadowBlur[p716] [= *value*]**

Returns the current level of blur applied to shadows.

Can be set, to change the blur level. Values that are not finite numbers greater than or equal to zero are ignored.

The **shadowColor** attribute sets the color of the shadow.

When the context is created, the shadowColor[p716] attribute initially must be transparent black.

On getting, the serialization of the color[p697] must be returned.

On setting, the new value must be parsed[p61] with this canvas[p661] element and the color assigned. If parsing the value results in failure then it must be ignored, and the attribute must retain its previous value. [CSSCOLOR][p1411]

The **shadowOffsetX** and **shadowOffsetY** attributes specify the distance that the shadow will be offset in the positive horizontal and positive vertical distance respectively. Their values are in coordinate space units. They are not affected by the current transformation matrix.

When the context is created, the shadow offset attributes must initially have the value 0.

On getting, they must return their current value. On setting, the attribute being set must be set to the new value, except if the value is infinite or NaN, in which case the new value must be ignored.

The **shadowBlur** attribute specifies the level of the blurring effect. (The units do not map to coordinate space units, and are not affected by the current transformation matrix.)

When the context is created, the shadowBlur[p716] attribute must initially have the value 0.

On getting, the attribute must return its current value. On setting the attribute must be set to the new value, except if the value is negative, infinite or NaN, in which case the new value must be ignored.

Shadows are only drawn if the opacity component of the alpha component of the color of shadowColor[p716] is nonzero and either the shadowBlur[p716] is nonzero, or the shadowOffsetX[p716] is nonzero, or the shadowOffsetY[p716] is nonzero.

When shadows are drawn[p716], they must be rendered as follows:

1. Let *A* be an infinite transparent black bitmap on which the source image for which a shadow is being created has been rendered.
2. Let *B* be an infinite transparent black bitmap, with a coordinate space and an origin identical to *A*.
3. Copy the alpha channel of *A* to *B*, offset by shadowOffsetX[p716] in the positive *x* direction, and shadowOffsetY[p716] in the positive *y* direction.
4. If shadowBlur[p716] is greater than 0:
    1. Let σ be half the value of shadowBlur[p716].
    2. Perform a 2D Gaussian Blur on *B*, using σ as the standard deviation.

    User agents may limit values of σ to an implementation-specific maximum value to avoid exceeding hardware limitations

during the Gaussian blur operation.

5. Set the red, green, and blue components of every pixel in *B* to the red, green, and blue components (respectively) of the color of shadowColor[p716].

6. Multiply the alpha component of every pixel in *B* by the alpha component of the color of shadowColor[p716].

7. The shadow is in the bitmap *B*, and is rendered as part of the drawing model[p718] described below.

If the current compositing and blending operator[p715] is "copy", then shadows effectively won't render (since the shape will overwrite the shadow).

4.12.5.1.19 Filters §[p717]

All drawing operations on an object which implements the CanvasFilters[p667] interface are affected by the global **filter** attribute.

For web developers (non-normative)

***context*.filter[p717] [= *value*]**

Returns the current filter.

Can be set, to change the filter. Values can either be the string "none" or a string parseable as a <filter-value-list>. Other values are ignored.

Such objects have an associated **current filter**, which is a string. Initially the current filter[p717] is set to the string "none". Whenever the value of the current filter[p717] is the string "none" filters will be disabled for the context.

The filter[p717] getter steps are to return this's current filter[p717].

The filter[p717] setter steps are:

1. If the given value is "none", then set this's current filter[p717] to "none" and return.

2. Let *parsedValue* be the result of parsing the given values as a <filter-value-list>. If any property-independent style sheet syntax like 'inherit' or 'initial' is present, then this parsing must return failure.

3. If *parsedValue* is failure, then return.

4. Set this's current filter[p717] to the given value.

Note

Though context.filter[p717] = "none" *will disable filters for the context,* context.filter[p717] = "", context.filter[p717] = null, *and* context.filter[p717] = undefined *are all treated as unparseable inputs and the value of the current filter[p717] is left unchanged.*

Coordinates used in the value of the current filter[p717] are interpreted such that one pixel is equivalent to one SVG user space unit and to one canvas coordinate space unit. Filter coordinates are not affected by the current transformation matrix[p693]. The current transformation matrix affects only the input to the filter. Filters are applied in the output bitmap[p671]'s coordinate space.

When the value of the current filter[p717] is a string parsable as a <filter-value-list> which defines lengths using percentages or using 'em' or 'ex' units, these must be interpreted relative to the computed value of the 'font-size' property of the font style source object[p680] at the time that the attribute is set. If the computed values are undefined for a particular case (e.g. because the font style source object[p680] is not an element or is not being rendered[p1325]), then the relative keywords must be interpreted relative to the default value of the font[p680] attribute. The 'larger' and 'smaller' keywords are not supported.

If the value of the current filter[p717] is a string parseable as a <filter-value-list> with a reference to an SVG filter in the same document, and this SVG filter changes, then the changed filter is used for the next draw operation.

If the value of the current filter[p717] is a string parseable as a <filter-value-list> with a reference to an SVG filter in an external resource document and that document is not loaded when a drawing operation is invoked, then the drawing operation must proceed with no filtering.

4.12.5.1.20 Working with externally-defined SVG filters §[p718]

This section is non-normative.

Since drawing is performed using filter value "none" until an externally-defined filter has finished loading, authors might wish to determine whether such a filter has finished loading before proceeding with a drawing operation. One way to accomplish this is to load the externally-defined filter elsewhere within the same page in some element that sends a `load` event (for example, an SVG `use` element), and wait for the `load` event to be dispatched.

4.12.5.1.21 Drawing model §[p718]

When a shape or image is painted, user agents must follow these steps, in the order given (or act as if they do):

1. Render the shape or image onto an infinite transparent black bitmap, creating image *A*, as described in the previous sections. For shapes, the current fill, stroke, and line styles must be honored, and the stroke must itself also be subjected to the current transformation matrix.

2. When the current filter[p717] is set to a value other than "none" and all the externally-defined filters it references, if any, are in documents that are currently loaded, then use image *A* as the input to the current filter[p717], creating image *B*. If the current filter[p717] is a string parseable as a <filter-value-list>, then draw using the current filter[p717] in the same manner as SVG.

   Otherwise, let *B* be an alias for *A*.

3. When shadows are drawn[p716], render the shadow from image *B*, using the current shadow styles, creating image *C*.

4. When shadows are drawn[p716], multiply the alpha component of every pixel in *C* by `global_alpha`[p715].

5. When shadows are drawn[p716], composite *C* within the clipping region[p704] over the current output bitmap[p671] using the current compositing and blending operator[p715].

6. Multiply the alpha component of every pixel in *B* by `global_alpha`[p715].

7. Composite *B* within the clipping region[p704] over the current output bitmap[p671] using the current compositing and blending operator[p715].

When compositing onto the output bitmap[p671], pixels that would fall outside of the output bitmap[p671] must be discarded.

4.12.5.1.22 Best practices §[p718]

When a canvas is interactive, authors should include focusable[p817] elements in the element's fallback content corresponding to each focusable[p817] part of the canvas, as in the example above[p705].

When rendering focus rings, to ensure that focus rings have the appearance of native focus rings, authors should use the `drawFocusIfNeeded()`[p707] method, passing it the element for which a ring is being drawn. This method only draws the focus ring if the element is focused[p817], so that it can simply be called whenever drawing the element, without checking whether the element is focused or not first.

In addition to drawing focus rings, authors should use the `scrollPathIntoView()`[p707] method when an element in the canvas is focused, to make sure it is visible on the screen (if applicable).

Authors should avoid implementing text editing controls using the `canvas`[p661] element. Doing so has a large number of disadvantages:

- Mouse placement of the caret has to be reimplemented.
- Keyboard movement of the caret has to be reimplemented (possibly across lines, for multiline text input).
- Scrolling of the text control has to be implemented (horizontally for long lines, vertically for multiline input).
- Native features such as copy-and-paste have to be reimplemented.
- Native features such as spell-checking have to be reimplemented.
- Native features such as drag-and-drop have to be reimplemented.

- Native features such as page-wide text search have to be reimplemented.
- Native features specific to the user, for example custom text services, have to be reimplemented. This is close to impossible since each user might have different services installed, and there is an unbounded set of possible such services.
- Bidirectional text editing has to be reimplemented.
- For multiline text editing, line wrapping has to be implemented for all relevant languages.
- Text selection has to be reimplemented.
- Dragging of bidirectional text selections has to be reimplemented.
- Platform-native keyboard shortcuts have to be reimplemented.
- Platform-native input method editors (IMEs) have to be reimplemented.
- Undo and redo functionality has to be reimplemented.
- Accessibility features such as magnification following the caret or selection have to be reimplemented.

This is a huge amount of work, and authors are most strongly encouraged to avoid doing any of it by instead using the `input` [p512] element, the `textarea` [p570] element, or the `contenteditable` [p833] attribute.

4.12.5.1.23 Examples §[p71] 9

This section is non-normative.

Example

Here is an example of a script that uses canvas to draw pretty glowing lines.

```
<canvas width="800" height="450"></canvas>
<script>

 var context = document.getElementsByTagName('canvas')[0].getContext('2d');

 var lastX = context.canvas.width * Math.random();
 var lastY = context.canvas.height * Math.random();
 var hue = 0;
 function line() {
   context.save();
   context.translate(context.canvas.width/2, context.canvas.height/2);
   context.scale(0.9, 0.9);
   context.translate(-context.canvas.width/2, -context.canvas.height/2);
   context.beginPath();
   context.lineWidth = 5 + Math.random() * 10;
   context.moveTo(lastX, lastY);
   lastX = context.canvas.width * Math.random();
   lastY = context.canvas.height * Math.random();
   context.bezierCurveTo(context.canvas.width * Math.random(),
                         context.canvas.height * Math.random(),
                         context.canvas.width * Math.random(),
                         context.canvas.height * Math.random(),
                         lastX, lastY);

   hue = hue + 10 * Math.random();
   context.strokeStyle = 'hsl(' + hue + ', 50%, 50%)';
   context.shadowColor = 'white';
   context.shadowBlur = 10;
   context.stroke();
   context.restore();
 }
 setInterval(line, 50);
```

```
 function blank() {
   context.fillStyle = 'rgba(0,0,0,0.1)';
   context.fillRect(0, 0, context.canvas.width, context.canvas.height);
 }
 setInterval(blank, 40);

</script>
```

Example

The 2D rendering context for canvas[p661] is often used for sprite-based games. The following example demonstrates this:

Here is the source for this example:

```
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Blue Robot Demo</title>
<style>
  html { overflow: hidden; min-height: 200px; min-width: 380px; }
  body { height: 200px; position: relative; margin: 8px; }
  .buttons { position: absolute; bottom: 0px; left: 0px; margin: 4px; }
</style>
<canvas width="380" height="200"></canvas>
<script>
 var Landscape = function (context, width, height) {
   this.offset = 0;
   this.width = width;
   this.advance = function (dx) {
     this.offset += dx;
   };
   this.horizon = height * 0.7;
   // This creates the sky gradient (from a darker blue to white at the bottom)
   this.sky = context.createLinearGradient(0, 0, 0, this.horizon);
   this.sky.addColorStop(0.0, 'rgb(55,121,179)');
   this.sky.addColorStop(0.7, 'rgb(121,194,245)');
   this.sky.addColorStop(1.0, 'rgb(164,200,214)');
   // this creates the grass gradient (from a darker green to a lighter green)
   this.earth = context.createLinearGradient(0, this.horizon, 0, height);
   this.earth.addColorStop(0.0, 'rgb(81,140,20)');
   this.earth.addColorStop(1.0, 'rgb(123,177,57)');
   this.paintBackground = function (context, width, height) {
     // first, paint the sky and grass rectangles
     context.fillStyle = this.sky;
```

```
      context.fillRect(0, 0, width, this.horizon);
      context.fillStyle = this.earth;
      context.fillRect(0, this.horizon, width, height-this.horizon);
      // then, draw the cloudy banner
      // we make it cloudy by having the draw text off the top of the
      // canvas, and just having the blurred shadow shown on the canvas
      context.save();
      context.translate(width-((this.offset+(this.width*3.2)) % (this.width*4.0))+0, 0);
      context.shadowColor = 'white';
      context.shadowOffsetY = 30+this.horizon/3; // offset down on canvas
      context.shadowBlur = '5';
      context.fillStyle = 'white';
      context.textAlign = 'left';
      context.textBaseline = 'top';
      context.font = '20px sans-serif';
      context.fillText('WHATWG ROCKS', 10, -30); // text up above canvas
      context.restore();
      // then, draw the background tree
      context.save();
      context.translate(width-((this.offset+(this.width*0.2)) % (this.width*1.5))+30, 0);
      context.beginPath();
      context.fillStyle = 'rgb(143,89,2)';
      context.lineStyle = 'rgb(10,10,10)';
      context.lineWidth = 2;
      context.rect(0, this.horizon+5, 10, -50); // trunk
      context.fill();
      context.stroke();
      context.beginPath();
      context.fillStyle = 'rgb(78,154,6)';
      context.arc(5, this.horizon-60, 30, 0, Math.PI*2); // leaves
      context.fill();
      context.stroke();
      context.restore();
    };
    this.paintForeground = function (context, width, height) {
      // draw the box that goes in front
      context.save();
      context.translate(width-((this.offset+(this.width*0.7)) % (this.width*1.1))+0, 0);
      context.beginPath();
      context.rect(0, this.horizon - 5, 25, 25);
      context.fillStyle = 'rgb(220,154,94)';
      context.lineStyle = 'rgb(10,10,10)';
      context.lineWidth = 2;
      context.fill();
      context.stroke();
      context.restore();
    };
  };
</script>
<script>
  var BlueRobot = function () {
    this.sprites = new Image();
    this.sprites.src = 'blue-robot.png'; // this sprite sheet has 8 cells
    this.targetMode = 'idle';
    this.walk = function () {
      this.targetMode = 'walk';
    };
    this.stop = function () {
      this.targetMode = 'idle';
    };
```

```
    this.frameIndex = {
      'idle': [0], // first cell is the idle frame
      'walk': [1,2,3,4,5,6], // the walking animation is cells 1-6
      'stop': [7], // last cell is the stopping animation
    };
    this.mode = 'idle';
    this.frame = 0; // index into frameIndex
    this.tick = function () {
      // this advances the frame and the robot
      // the return value is how many pixels the robot has moved
      this.frame += 1;
      if (this.frame >= this.frameIndex[this.mode].length) {
        // we've reached the end of this animation cycle
        this.frame = 0;
        if (this.mode != this.targetMode) {
          // switch to next cycle
          if (this.mode == 'walk') {
            // we need to stop walking before we decide what to do next
            this.mode = 'stop';
          } else if (this.mode == 'stop') {
            if (this.targetMode == 'walk')
              this.mode = 'walk';
            else
              this.mode = 'idle';
          } else if (this.mode == 'idle') {
            if (this.targetMode == 'walk')
              this.mode = 'walk';
          }
        }
      }
      if (this.mode == 'walk')
        return 8;
      return 0;
    },
    this.paint = function (context, x, y) {
      if (!this.sprites.complete) return;
      // draw the right frame out of the sprite sheet onto the canvas
      // we assume each frame is as high as the sprite sheet
      // the x,y coordinates give the position of the bottom center of the sprite
      context.drawImage(this.sprites,
                        this.frameIndex[this.mode][this.frame] * this.sprites.height, 0,
this.sprites.height, this.sprites.height,
                        x-this.sprites.height/2, y-this.sprites.height, this.sprites.height,
this.sprites.height);
    };
  };
</script>
<script>
  var canvas = document.getElementsByTagName('canvas')[0];
  var context = canvas.getContext('2d');
  var landscape = new Landscape(context, canvas.width, canvas.height);
  var blueRobot = new BlueRobot();
  // paint when the browser wants us to, using requestAnimationFrame()
  function paint() {
    context.clearRect(0, 0, canvas.width, canvas.height);
    landscape.paintBackground(context, canvas.width, canvas.height);
    blueRobot.paint(context, canvas.width/2, landscape.horizon*1.1);
    landscape.paintForeground(context, canvas.width, canvas.height);
    requestAnimationFrame(paint);
  }
```

```
 paint();
 // but tick every 100ms, so that we don't slow down when we don't paint
 setInterval(function () {
   var dx = blueRobot.tick();
   landscape.advance(dx);
 }, 100);
</script>

4.12.5.2 The ImageBitmap[p1120] rendering context §[p723]

4.12.5.2.1 Introduction §[p723]

ImageBitmapRenderingContext[p723] is a performance-oriented interface that provides a low overhead method for displaying the contents of ImageBitmap[p1120] objects. It uses transfer semantics to reduce overall memory consumption. It also streamlines performance by avoiding intermediate compositing, unlike the drawImage()[p707] method of CanvasRenderingContext2D[p666].

Using an img[p338] element as an intermediate for getting an image resource into a canvas, for example, would result in two copies of the decoded image existing in memory at the same time: the img[p338] element's copy, and the one in the canvas's backing store. This memory cost can be prohibitive when dealing with extremely large images. This can be avoided by using ImageBitmapRenderingContext[p723].

Example

Using ImageBitmapRenderingContext[p723], here is how to transcode an image to the JPEG format in a memory- and CPU-efficient way:

```
createImageBitmap(inputImageBlob).then(image => {
  const canvas = document.createElement('canvas');
  const context = canvas.getContext('bitmaprenderer');
  context.transferFromImageBitmap(image);

  canvas.toBlob(outputJPEGBlob => {
    // Do something with outputJPEGBlob.
  }, 'image/jpeg');
});
```

4.12.5.2.2 The ImageBitmapRenderingContext[p723] interface §[p723]

✔ MDN

IDL

```
[Exposed=(Window,Worker)]
interface ImageBitmapRenderingContext {
  readonly attribute (HTMLCanvasElement or OffscreenCanvas) canvas;
  undefined transferFromImageBitmap(ImageBitmap? bitmap);
};

dictionary ImageBitmapRenderingContextSettings {
```

```
  boolean alpha = true;
};
```

For web developers (non-normative)

***context* = *canvas*.getContext[p664]('bitmaprenderer' [, { [alpha[p725]: false] }])**

Returns an ImageBitmapRenderingContext[p723] object that is permanently bound to a particular canvas[p661] element.

If the alpha[p725] setting is provided and set to false, then the canvas is forced to always be opaque.

***context*.canvas[p724]**

Returns the canvas[p661] element that the context is bound to.

***context*.transferFromImageBitmap[p725](imageBitmap)**

Transfers the underlying bitmap data[p1121] from *imageBitmap* to *context*, and the bitmap becomes the contents of the canvas[p661] element to which *context* is bound.

***context*.transferFromImageBitmap[p725](null)**

Replaces contents of the canvas[p661] element to which *context* is bound with a transparent black bitmap whose size corresponds to the width[p662] and height[p662] content attributes of the canvas[p661] element.

The **canvas** attribute must return the value it was initialized to when the object was created.

An ImageBitmapRenderingContext[p723] object has an **output bitmap**, which is a reference to bitmap data[p1121].

An ImageBitmapRenderingContext[p723] object has a **bitmap mode**, which can be set to **valid** or **blank**. A value of valid[p724] indicates that the context's output bitmap[p724] refers to bitmap data[p1121] that was acquired via transferFromImageBitmap()[p725]. A value blank[p724] indicates that the context's output bitmap[p724] is a default transparent bitmap.

An ImageBitmapRenderingContext[p723] object also has an **alpha** flag, which can be set to true or false. When an ImageBitmapRenderingContext[p723] object has its alpha[p724] flag set to false, the contents of the canvas[p661] element to which the context is bound are obtained by compositing the context's output bitmap[p724] onto an opaque black bitmap of the same size using the source-over compositing operator. If the alpha[p724] flag is set to true, then the output bitmap[p724] is used as the contents of the canvas[p661] element to which the context is bound. [COMPOSITE][p1410]

Note

The step of compositing over an opaque black bitmap ought to be elided whenever equivalent results can be obtained more efficiently by other means.

When a user agent is required to **set an ImageBitmapRenderingContext's output bitmap**, with a *context* argument that is an ImageBitmapRenderingContext[p723] object and an optional argument *bitmap* that refers to bitmap data[p1121], it must run these steps:

1. If a *bitmap* argument was not provided, then:
    1. Set *context*'s bitmap mode[p724] to blank[p724].
    2. Let *canvas* be the canvas[p661] element to which *context* is bound.
    3. Set *context*'s output bitmap[p724] to be transparent black with a natural width equal to the numeric value[p662] of *canvas*'s width[p662] attribute and a natural height equal to the numeric value[p662] of *canvas*'s height[p662] attribute, those values being interpreted in CSS pixels.
    4. Set the output bitmap[p724]'s origin-clean[p663] flag to true.
2. If a *bitmap* argument was provided, then:
    1. Set *context*'s bitmap mode[p724] to valid[p724].
    2. Set *context*'s output bitmap[p724] to refer to the same underlying bitmap data as *bitmap*, without making a copy.

        Note

        The origin-clean[p663] flag of bitmap *is included in the bitmap data to be referenced by* context's *output bitmap[p724].*

The **ImageBitmapRenderingContext creation algorithm**, which is passed a *target* and *options*, consists of running these steps:

1. Let *settings* be the result of converting *options* to the dictionary type ImageBitmapRenderingContextSettings[p723]. (This can throw an exception.)
2. Let *context* be a new ImageBitmapRenderingContext[p723] object.
3. Initialize *context*'s canvas[p673] attribute to point to *target*.
4. Set *context*'s output bitmap[p724] to the same bitmap as *target*'s bitmap (so that they are shared).
5. Run the steps to set an ImageBitmapRenderingContext's output bitmap[p724] with *context*.
6. Initialize *context*'s alpha[p724] flag to true.
7. Process each of the members of *settings* as follows:

   alpha

   If false, then set *context*'s alpha[p724] flag to false.
8. Return *context*.

The **transferFromImageBitmap(*bitmap*)** method, when invoked, must run these steps:

1. Let *bitmapContext* be the ImageBitmapRenderingContext[p723] object on which the transferFromImageBitmap()[p725] method was called.
2. If *bitmap* is null, then run the steps to set an ImageBitmapRenderingContext's output bitmap[p724], with *bitmapContext* as the *context* argument and no *bitmap* argument, then return.
3. If the value of *bitmap*'s [[Detached]][p116] internal slot is set to true, then throw an "InvalidStateError" DOMException.
4. Run the steps to set an ImageBitmapRenderingContext's output bitmap[p724], with the *context* argument equal to *bitmapContext*, and the *bitmap* argument referring to *bitmap*'s underlying bitmap data[p1121].
5. Set the value of *bitmap*'s [[Detached]][p116] internal slot to true.
6. Unset *bitmap*'s bitmap data[p1121].

4.12.5.3 The OffscreenCanvas[p725] interface §[p725]

IDL

```
typedef (OffscreenCanvasRenderingContext2D or ImageBitmapRenderingContext or WebGLRenderingContext or
WebGL2RenderingContext or GPUCanvasContext) OffscreenRenderingContext;

dictionary ImageEncodeOptions {
  DOMString type = "image/png";
  unrestricted double quality;
};

enum OffscreenRenderingContextId { "2d", "bitmaprenderer", "webgl", "webgl2", "webgpu" };

[Exposed=(Window,Worker), Transferable]
interface OffscreenCanvas : EventTarget {
  constructor([EnforceRange] unsigned long long width, [EnforceRange] unsigned long long height);

  attribute [EnforceRange] unsigned long long width;
  attribute [EnforceRange] unsigned long long height;

  OffscreenRenderingContext? getContext(OffscreenRenderingContextId contextId, optional any options =
null);
  ImageBitmap transferToImageBitmap();
  Promise<Blob> convertToBlob(optional ImageEncodeOptions options = {});
```

```
  attribute EventHandler oncontextlost;
  attribute EventHandler oncontextrestored;
};
```

Note

OffscreenCanvas[p725] is an EventTarget, so both OffscreenCanvasRenderingContext2D[p729] and WebGL can fire events at it. OffscreenCanvasRenderingContext2D[p729] can fire contextlost[p1406] and contextrestored[p1406], and WebGL can fire `webglcontextlost` *and* `webglcontextrestored`*. [WEBGL][p1418]*

OffscreenCanvas[p725] objects are used to create rendering contexts, much like an HTMLCanvasElement[p661], but with no connection to the DOM. This makes it possible to use canvas rendering contexts in workers[p1150].

An OffscreenCanvas[p725] object may hold a weak reference to a **placeholder canvas element**, which is typically in the DOM, whose embedded content is provided by the OffscreenCanvas[p725] object. The bitmap of the OffscreenCanvas[p725] object is pushed to the placeholder canvas element[p726] by calling the **commit()** method of the OffscreenCanvas[p725] object's rendering context. All rendering context types that can be created by an OffscreenCanvas[p725] object must implement a commit()[p726] method. The exact behavior of the commit method (e.g. whether it copies or transfers bitmaps) may vary, as defined by the rendering contexts' respective specifications. Only the 2D context for offscreen canvases[p729] is defined in this specification.

For web developers (non-normative)

***offscreenCanvas* = new OffscreenCanvas[p726](*width*, *height*)**

Returns a new OffscreenCanvas[p725] object that is not linked to a placeholder canvas element[p726], and whose bitmap's size is determined by the *width* and *height* arguments.

***context* = *offscreenCanvas*.getContext[p727](*contextId* [, *options*])**

Returns an object that exposes an API for drawing on the OffscreenCanvas[p725] object. *contextId* specifies the desired API: "2d[p727]", "bitmaprenderer[p727]", "webgl[p727]", "webgl2[p727]", or "webgpu[p727]". *options* is handled by that API.

This specification defines the "2d[p664]" context below, which is similar but distinct from the "2d[p727]" context that is created from a canvas[p661] element. The WebGL specifications define the "webgl[p727]" and "webgl2[p727]" contexts. *WebGPU* defines the "webgpu[p727]" context. [WEBGL][p1418] [WEBGPU][p1418]

Returns null if the canvas has already been initialized with another context type (e.g., trying to get a "2d[p727]" context after getting a "webgl[p727]" context).

An OffscreenCanvas[p725] object has an internal **bitmap** that is initialized when the object is created. The width and height of the bitmap[p726] are equal to the values of the width[p728] and height[p728] attributes of the OffscreenCanvas[p725] object. Initially, all the bitmap's pixels are transparent black.

An OffscreenCanvas[p725] object can have a rendering context bound to it. Initially, it does not have a bound rendering context. To keep track of whether it has a rendering context or not, and what kind of rendering context it is, an OffscreenCanvas[p725] object also has a **context mode**, which is initially **none** but can be changed to either **2d**, **bitmaprenderer**, **webgl**, **webgl2**, **webgpu**, or **detached** by algorithms defined in this specification.

The constructor **OffscreenCanvas(*width*, *height*)**, when invoked, must create a new OffscreenCanvas[p725] object with its bitmap[p726] initialized to a rectangular array of transparent black pixels of the dimensions specified by *width* and *height*; and its width[p728] and height[p728] attributes initialized to *width* and *height* respectively.

OffscreenCanvas[p725] objects are transferable[p115]. Their transfer steps[p116], given *value* and *dataHolder*, are as follows:

1. If *value*'s context mode[p726] is not equal to none[p726], then throw an "InvalidStateError" DOMException.
2. Set *value*'s context mode[p726] to detached[p726].
3. Let *width* and *height* be the dimensions of *value*'s bitmap[p726].
4. Unset *value*'s bitmap[p726].
5. Set *dataHolder*.[[Width]] to *width* and *dataHolder*.[[Height]] to *height*.
6. Set *dataHolder*.[[PlaceholderCanvas]] to be a weak reference to *value*'s placeholder canvas element[p726], if *value* has one, or null if it does not.

Their transfer-receiving steps[p116], given *dataHolder* and *value*, are:

1. Initialize *value*'s bitmap[p726] to a rectangular array of transparent black pixels with width given by *dataHolder*.[[Width]] and height given by *dataHolder*.[[Height]].

2. If *dataHolder*.[[PlaceholderCanvas]] is not null, set *value*'s placeholder canvas element[p726] to *dataHolder*.[[PlaceholderCanvas]] (while maintaining the weak reference semantics).

The **`getContext(contextId, options)`** method of an `OffscreenCanvas`[p725] object, when invoked, must run these steps:

1. If *options* is not an object, then set *options* to null.

2. Set *options* to the result of converting *options* to a JavaScript value.

3. Run the steps in the cell of the following table whose column header matches this `OffscreenCanvas`[p725] object's context mode[p726] and whose row header matches *contextId*:

	none[p726]	**2d**[p726]	**bitmaprenderer**[p726]	**webgl**[p726] **or** **webgl2**[p726]	**webgpu**[p726]	**detached**[p726]
`"2d"`	1. Let *context* be the result of running the offscreen 2D context creation algorithm[p730] given this and *options*. 2. Set this's context mode[p726] to 2d[p726]. 3. Return *context*.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Return null.	Return null.	Throw an `"InvalidStateError" DOMException`.
`"bitmaprenderer"`	1. Let *context* be the result of running the `ImageBitmapRenderingContext` creation algorithm[p725] given this and *options*. 2. Set this's context mode[p726] to bitmaprenderer[p726]. 3. Return *context*.	Return null.	Return the same object as was returned the last time the method was invoked with this same first argument.	Return null.	Return null.	Throw an `"InvalidStateError" DOMException`.
`"webgl"` or `"webgl2"`	1. Let *context* be the result of following the instructions given in the WebGL specifications' *Context Creation* sections. [WEBGL][p1418] 2. If *context* is null, then return null; otherwise set this's context mode[p726] to webgl[p726] or webgl2[p726]. 3. Return *context*.	Return null.	Return null.	Return the same value as was returned the last time the method was invoked with this same first argument.	Return null.	Throw an `"InvalidStateError" DOMException`.
`"webgpu"`	1. Let *context* be the result of following the instructions given in *WebGPU*'s Canvas Rendering section. [WEBGPU][p1418] 2. If *context* is null, then return null; otherwise set this's context mode[p726] to webgpu[p726]. 3. Return *context*.	Return null.	Return null.	Return null.	Return the same value as was returned the last time the method was invoked with this same first argument.	Throw an `"InvalidStateError" DOMException`.

For web developers (non-normative)

***offscreenCanvas*.width**[p728] **[= *value*]**

***offscreenCanvas*.height**[p728] **[= *value*]**

These attributes return the dimensions of the OffscreenCanvas[p725] object's bitmap[p726].

They can be set, to replace the bitmap[p726] with a new, transparent black bitmap of the specified dimensions (effectively resizing it).

If either the **width** or **height** attributes of an OffscreenCanvas[p725] object are set (to a new value or to the same value as before) and the OffscreenCanvas[p725] object's context mode[p726] is 2d[p726], then reset the rendering context to its default state[p674] and resize the OffscreenCanvas[p725] object's bitmap[p726] to the new values of the width[p728] and height[p728] attributes.

The resizing behavior for "webgl[p727]" and "webgl2[p727]" contexts is defined in the WebGL specifications. [WEBGL][p1418]

The resizing behavior for "webgpu[p727]" context is defined in *WebGPU*. [WEBGPU][p1418]

Note

If an OffscreenCanvas[p725] object whose dimensions were changed has a placeholder canvas element[p726], then the placeholder canvas element[p726]'s natural size will only be updated via the commit()[p726] method of the OffscreenCanvas[p725] object's rendering context.

For web developers (non-normative)

***promise* = *offscreenCanvas*.convertToBlob**[p728]**([*options*])**

Returns a promise that will fulfill with a new Blob object representing a file containing the image in the OffscreenCanvas[p725] object.

The argument, if provided, is a dictionary that controls the encoding options of the image file to be created. The type[p728] field specifies the file format and has a default value of "image/png[p1408]"; that type is also used if the requested type isn't supported. If the image format supports variable quality (such as "image/jpeg[p1408]"), then the quality[p728] field is a number in the range 0.0 to 1.0 inclusive indicating the desired quality level for the resulting image.

***canvas*.transferToImageBitmap**[p728]**()**

Returns a newly created ImageBitmap[p1120] object with the image in the OffscreenCanvas[p725] object. The image in the OffscreenCanvas[p725] object is replaced with a new blank image.

The **convertToBlob(*options*)** method, when invoked, must run the following steps:

1. If the value of this OffscreenCanvas[p725] object's [[Detached]][p116] internal slot is set to true, then return a promise rejected with an "InvalidStateError" DOMException.
2. If this OffscreenCanvas[p725] object's context mode[p726] is 2d[p726] and the rendering context's bitmap[p729]'s origin-clean[p730] flag is set to false, then return a promise rejected with a "SecurityError" DOMException.
3. If this OffscreenCanvas[p725] object's bitmap[p726] has no pixels (i.e., either its horizontal dimension or its vertical dimension is zero) then return a promise rejected with an "IndexSizeError" DOMException.
4. Let *bitmap* be a copy of this OffscreenCanvas[p725] object's bitmap[p726].
5. Let *result* be a new promise object.
6. Run these steps in parallel[p43]:
    1. Let *file* be a serialization of *bitmap* as a file[p731], with *options*'s **type** and **quality** if present.
    2. Queue an element task[p1073] on the canvas blob serialization task source[p665] given the canvas[p661] element to run these steps:
        1. If *file* is null, then reject *result* with an "EncodingError" DOMException.
        2. Otherwise, resolve *result* with a new Blob object, created in the relevant realm[p1039] of this OffscreenCanvas[p725] object, representing *file*. [FILEAPI][p1413]
7. Return *result*.

The **transferToImageBitmap()** method, when invoked, must run the following steps:

1. If the value of this OffscreenCanvas[p725] object's [[Detached]][p116] internal slot is set to true, then throw an "InvalidStateError" DOMException.

2. If this OffscreenCanvas[p725] object's context mode[p726] is set to none[p726], then throw an "InvalidStateError" DOMException.

3. Let *image* be a newly created ImageBitmap[p1120] object that references the same underlying bitmap data as this OffscreenCanvas[p725] object's bitmap[p726].

4. Set this OffscreenCanvas[p725] object's bitmap[p726] to reference a newly created bitmap of the same dimensions and color space as the previous bitmap, and with its pixels initialized to transparent black, or opaque black if the rendering context's alpha[p730] flag is set to false.

   Note

   This means that if the rendering context of this OffscreenCanvas[p725] is a WebGLRenderingContext, the value of preserveDrawingBuffer will have no effect. [WEBGL][p1418]

5. Return *image*.

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported, as event handler IDL attributes[p1084], by all objects implementing the OffscreenCanvas[p725] interface:

Event handler[p1083]	Event handler event type[p1085]
oncontextlost	contextlost[p1406]
oncontextrestored	contextrestored[p1406]

MDN

4.12.5.3.1 The offscreen 2D rendering context §[p729]

IDL
```
[Exposed=(Window,Worker)]
interface OffscreenCanvasRenderingContext2D {
  undefined commit();
  readonly attribute OffscreenCanvas canvas;
};

OffscreenCanvasRenderingContext2D includes CanvasState;
OffscreenCanvasRenderingContext2D includes CanvasTransform;
OffscreenCanvasRenderingContext2D includes CanvasCompositing;
OffscreenCanvasRenderingContext2D includes CanvasImageSmoothing;
OffscreenCanvasRenderingContext2D includes CanvasFillStrokeStyles;
OffscreenCanvasRenderingContext2D includes CanvasShadowStyles;
OffscreenCanvasRenderingContext2D includes CanvasFilters;
OffscreenCanvasRenderingContext2D includes CanvasRect;
OffscreenCanvasRenderingContext2D includes CanvasDrawPath;
OffscreenCanvasRenderingContext2D includes CanvasText;
OffscreenCanvasRenderingContext2D includes CanvasDrawImage;
OffscreenCanvasRenderingContext2D includes CanvasImageData;
OffscreenCanvasRenderingContext2D includes CanvasPathDrawingStyles;
OffscreenCanvasRenderingContext2D includes CanvasTextDrawingStyles;
OffscreenCanvasRenderingContext2D includes CanvasPath;
```

The OffscreenCanvasRenderingContext2D[p729] object is a rendering context for drawing to the bitmap[p726] of an OffscreenCanvas[p725] object. It is similar to the CanvasRenderingContext2D[p666] object, with the following differences:

- there is no support for user interface[p668] features;
- its canvas[p731] attribute refers to an OffscreenCanvas[p725] object rather than a canvas[p661] element;
- it has a commit()[p730] method for pushing the rendered image to the context's OffscreenCanvas[p725] object's placeholder canvas element[p726].

An OffscreenCanvasRenderingContext2D[p729] object has a **bitmap** that is initialized when the object is created.

The bitmap[p729] has an **origin-clean** flag, which can be set to true or false. Initially, when one of these bitmaps is created, its origin-clean[p730] flag must be set to true.

An `OffscreenCanvasRenderingContext2D`[p729] object also has an **alpha** flag, which can be set to true or false. Initially, when the context is created, its alpha flag must be set to true. When an `OffscreenCanvasRenderingContext2D`[p729] object has its alpha[p730] flag set to false, then its alpha channel must be fixed to 1.0 (fully opaque) for all pixels, and attempts to change the alpha component of any pixel must be silently ignored.

An `OffscreenCanvasRenderingContext2D`[p729] object also has a **color space** setting of type `PredefinedColorSpace`[p666]. The color space for the context's bitmap[p729] is set to the context's color space[p730].

An `OffscreenCanvasRenderingContext2D`[p729] object has an **associated `OffscreenCanvas` object**, which is the `OffscreenCanvas`[p725] object from which the `OffscreenCanvasRenderingContext2D`[p729] object was created.

For web developers (non-normative)

***offscreenCanvasRenderingContext2D*.commit[p730]()**

Copies the rendering context's bitmap[p729] to the bitmap of the placeholder canvas element[p726] of the associated `OffscreenCanvas` object[p730]. The copy operation is synchronous. Calling this method is not needed for the transfer, since it happens automatically during the event loop[p1071] execution.

***offscreenCanvas* = *offscreenCanvasRenderingContext2D*.canvas[p731]**

Returns the associated `OffscreenCanvas` object[p730].

The **offscreen 2D context creation algorithm**, which is passed a *target* (an `OffscreenCanvas`[p725] object) and optionally some arguments, consists of running the following steps:

1. If the algorithm was passed some arguments, let *arg* be the first such argument. Otherwise, let *arg* be undefined.
2. Let *settings* be the result of converting *arg* to the dictionary type `CanvasRenderingContext2DSettings`[p666]. (This can throw an exception.).
3. Let *context* be a new `OffscreenCanvasRenderingContext2D`[p729] object.
4. Set *context*'s associated `OffscreenCanvas` object[p730] to *target*.
5. If *settings*["`alpha`[p672]"] is false, then set *context*'s alpha[p730] flag to false.
6. Set *context*'s color space[p730] to *settings*["`colorSpace`[p672]"].
7. Set *context*'s bitmap[p729] to a newly created bitmap with the dimensions specified by the `width`[p728] and `height`[p728] attributes of *target*, and set *target*'s bitmap to the same bitmap (so that they are shared).
8. If *context*'s alpha[p730] flag is set to true, initialize all the pixels of *context*'s bitmap[p729] to transparent black. Otherwise, initialize the pixels to opaque black.
9. Return *context*.

The **`commit()`** method, when invoked, must run the following steps: MDN

1. If this `OffscreenCanvasRenderingContext2D`[p729]'s associated `OffscreenCanvas` object[p730] does not have a placeholder canvas element[p726], then return.
2. Let *image* be a copy of this `OffscreenCanvasRenderingContext2D`[p729]'s bitmap[p729], including the value of its origin-clean[p730] flag.
3. Queue an element task[p1073] on the DOM manipulation task source[p1080] given the placeholder canvas element[p726] to set the placeholder canvas element[p726]'s output bitmap[p671] to be a reference to *image*.

Note

If image *has different dimensions than the bitmap previously referenced as the placeholder canvas element[p726]'s output bitmap[p671], then this task will result in a change in the placeholder canvas element[p726]'s natural size, which can affect document layout.*

Note

Implementations are encouraged to short-circuit the graphics update steps of the window event loop[p1071] for the purposes of updating the contents of a placeholder canvas element[p726] to the display. This could mean, for example, that the commit()[p730] method can copy the bitmap contents directly to a graphics buffer that is mapped to the physical display location of the placeholder canvas element[p726]. This or similar short-circuiting approaches can significantly reduce display latency, especially in cases where the commit()[p730] method is invoked from a worker event loop[p1071] and the window event loop[p1071] of the placeholder canvas element[p726] is busy. However, such shortcuts cannot have any script-observable side-effects. This means that the committed bitmap still needs to be sent to the placeholder canvas element[p726], in case the element is used as a CanvasImageSource[p666], as an ImageBitmapSource[p1120], or in case toDataURL()[p665] or toBlob()[p665] are called on it.

The **canvas** attribute, on getting, must return this OffscreenCanvasRenderingContext2D[p729]'s associated OffscreenCanvas object[p730].

4.12.5.4 Color spaces and color space conversion §[p731]

The canvas[p661] APIs provide mechanisms for specifying the color space of the canvas's backing store. The default backing store color space for all canvas APIs is 'srgb'.

Color space conversion must be applied to the canvas's backing store when rendering the canvas to the output device. This color space conversion must be identical to the color space conversion that would be applied to an img[p338] element with a color profile that specifies the same color space[p672] as the canvas's backing store.

When drawing content to a 2D context, all inputs must be converted to the context's color space[p672] before drawing. Interpolation of gradient color stops must be performed on color values after conversion to the context's color space[p672]. Alpha blending must be performed on values after conversion to the context's color space[p672].

Note

There do not exist any inputs to a 2D context for which the color space is undefined. The color space for CSS colors is defined in CSS Color. *The color space for images that specify no color profile information is assumed to be 'srgb', as specified in the Color Spaces of Untagged Colors section of* CSS Color. *[CSSCOLOR][p1411]*

4.12.5.5 Serializing bitmaps to a file §[p731]

When a user agent is to create **a serialization of the bitmap as a file**, given a *type* and an optional *quality*, it must create an image file in the format given by *type*. If an error occurs during the creation of the image file (e.g. an internal encoder error), then the result of the serialization is null. [PNG][p1415]

The image file's pixel data must be the bitmap's pixel data scaled to one image pixel per coordinate space unit, and if the file format used supports encoding resolution metadata, the resolution must be given as 96dpi (one image pixel per CSS pixel).

If *type* is supplied, then it must be interpreted as a MIME type giving the format to use. If the type has any parameters, then it must be treated as not supported.

Example

For example, the value "image/png[p1408]" would mean to generate a PNG image, the value "image/jpeg[p1408]" would mean to generate a JPEG image, and the value "image/svg+xml[p1409]" would mean to generate an SVG image (which would require that the user agent track how the bitmap was generated, an unlikely, though potentially awesome, feature).

User agents must support PNG ("image/png[p1408]"). User agents may support other types. If the user agent does not support the requested type, then it must create the file using the PNG format. [PNG][p1415]

User agents must convert the provided type to ASCII lowercase before establishing if they support that type.

For image types that do not support an alpha channel, the serialized image must be the bitmap image composited onto an opaque black background using the source-over compositing operator.

For image types that support color profiles, the serialized image must include a color profile indicating the color space of the underlying bitmap. For image types that do not support color profiles, the serialized image must be converted to the 'srgb' color space using 'relative-colorimetric' rendering intent.

Note

Thus, in the 2D context, calling the drawImage() method to render the output of the toDataURL() or toBlob() method to the canvas, given the appropriate dimensions, has no visible effect beyond, at most, clipping colors of the canvas to a more narrow gamut.

If *type* is an image format that supports variable quality (such as "image/jpeg"), *quality* is given, and *type* is not "image/png", then, if Type(*quality*) is Number, and *quality* is in the range 0.0 to 1.0 inclusive, the user agent must treat *quality* as the desired quality level. Otherwise, the user agent must use its default quality value, as if the *quality* argument had not been given.

Note

The use of type-testing here, instead of simply declaring quality *as a Web IDL* `double`*, is a historical artifact.*

Note

Different implementations can have slightly different interpretations of "quality". When the quality is not specified, an implementation-specific default is used that represents a reasonable compromise between compression ratio, image quality, and encoding time.

4.12.5.6 Security with canvas elements

This section is non-normative.

Information leakage can occur if scripts from one origin can access information (e.g. read pixels) from images from another origin (one that isn't the same).

To mitigate this, bitmaps used with canvas elements and ImageBitmap objects are defined to have a flag indicating whether they are origin-clean. All bitmaps start with their origin-clean set to true. The flag is set to false when cross-origin images are used.

The toDataURL(), toBlob(), and getImageData() methods check the flag and will throw a "SecurityError" DOMException rather than leak cross-origin data.

The value of the origin-clean flag is propagated from a source canvas element's bitmap to a new ImageBitmap object by createImageBitmap(). Conversely, a destination canvas element's bitmap will have its origin-clean flags set to false by drawImage if the source image is an ImageBitmap object whose bitmap has its origin-clean flag set to false.

The flag can be reset in certain situations; for example, when changing the value of the width or the height content attribute of the canvas element to which a CanvasRenderingContext2D is bound, the bitmap is cleared and its origin-clean flag is reset.

When using an ImageBitmapRenderingContext, the value of the origin-clean flag is propagated from ImageBitmap objects when they are transferred to the canvas via transferFromImageBitmap().

4.12.5.7 Premultiplied alpha and the 2D rendering context

Premultiplied alpha refers to one way of representing transparency in an image, the other being non-premultiplied alpha.

Under non-premultiplied alpha, the red, green, and blue channels of a pixel represent that pixel's color, and its alpha channel represents that pixel's opacity.

Under premultiplied alpha, however, the red, green, and blue channels of a pixel represent the amounts of color that the pixel adds to the image, and its alpha channel represents the amount that the pixel obscures whatever is behind it.

Example

For instance, assuming the color channels range from 0 (off) to 255 (full intensity), these example colors are represented in the following ways:

CSS color representation	Premultiplied representation	Non-premultiplied representation	Description of color	Image of color blended above other content
rgba(255, 127, 0, 1)	255, 127, 0, 255	255, 127, 0, 255	Completely-opaque orange	
rgba(255, 255, 0, 0.5)	127, 127, 0, 127	255, 255, 0, 127	Halfway-opaque yellow	
Unrepresentable	255, 127, 0, 127	Unrepresentable	Additive halfway-opaque orange	
Unrepresentable	255, 127, 0, 0	Unrepresentable	Additive fully-transparent orange	
rgba(255, 127, 0, 0)	0, 0, 0, 0	255, 127, 0, 0	Fully-transparent ("invisible") orange	
rgba(0, 127, 255, 0)	0, 0, 0, 0	255, 127, 0, 0	Fully-transparent ("invisible") turquoise	

Converting a color value from a non-premultiplied representation to a premultiplied one involves multiplying the color's red, green, and blue channels by its alpha channel (remapping the range of the alpha channel such that "fully transparent" is 0, and "fully opaque" is 1).

Converting a color value from a premultiplied representation to a non-premultiplied one involves the inverse: dividing the color's red, green, and blue channels by its alpha channel.

As certain colors can only be represented under premultiplied alpha (for instance, additive colors), and others can only be represented under non-premultiplied alpha (for instance, "invisible" colors which hold certain red, green, and blue values even with no opacity); and division and multiplication on 8-bit integers (which is how canvas's colors are currently stored) entails a loss of precision, converting between premultiplied and non-premultiplied alpha is a lossy operation on colors that are not fully opaque.

A `CanvasRenderingContext2D`[p666]'s output bitmap[p671] and an `OffscreenCanvasRenderingContext2D`[p729]'s bitmap[p729] must use premultiplied alpha to represent transparent colors.

Note

It is important for canvas bitmaps to represent colors using premultiplied alpha because it affects the range of representable

colors. While additive colors cannot currently be drawn onto canvases directly because CSS colors are non-premultiplied and cannot represent them, it is still possible to, for instance, draw additive colors onto a WebGL canvas and then draw that WebGL canvas onto a 2D canvas via `drawImage()`[p707]*.*

4.13 Custom elements §[p73] 4

4.13.1 Introduction §[p73] 4

This section is non-normative.

Custom elements[p742] provide a way for authors to build their own fully-featured DOM elements. Although authors could always use non-standard elements in their documents, with application-specific behavior added after the fact by scripting or similar, such elements have historically been non-conforming and not very functional. By defining[p745] a custom element, authors can inform the parser how to properly construct an element and how elements of that class should react to changes.

Custom elements are part of a larger effort to "rationalise the platform", by explaining existing platform features (like the elements of HTML) in terms of lower-level author-exposed extensibility points (like custom element definition). Although today there are many limitations on the capabilities of custom elements—both functionally and semantically—that prevent them from fully explaining the behaviors of HTML's existing elements, we hope to shrink this gap over time.

4.13.1.1 Creating an autonomous custom element §[p73] 4

This section is non-normative.

For the purposes of illustrating how to create an autonomous custom element[p742], let's define a custom element that encapsulates rendering a small icon for a country flag. Our goal is to be able to use it like so:

```
<flag-icon country="nl"></flag-icon>
```

To do this, we first declare a class for the custom element, extending `HTMLElement`[p138]:

```
class FlagIcon extends HTMLElement {
  constructor() {
    super();
    this._countryCode = null;
  }

  static observedAttributes = ["country"];

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "country" due to observedAttributes
    this._countryCode = newValue;
    this._updateRendering();
  }
  connectedCallback() {
    this._updateRendering();
  }

  get country() {
    return this._countryCode;
  }
  set country(v) {
    this.setAttribute("country", v);
  }
```

```
  _updateRendering() {
    // Left as an exercise for the reader. But, you'll probably want to
    // check this.ownerDocument.defaultView to see if we've been
    // inserted into a document with a browsing context, and avoid
    // doing any work if not.
  }
}
```

We then need to use this class to define the element:

```
customElements.define("flag-icon", FlagIcon);
```

At this point, our above code will work! The parser, whenever it sees the `flag-icon` tag, will construct a new instance of our `FlagIcon` class, and tell our code about its new `country` attribute, which we then use to set the element's internal state and update its rendering (when appropriate).

You can also create `flag-icon` elements using the DOM API:

```
const flagIcon = document.createElement("flag-icon")
flagIcon.country = "jp"
document.body.appendChild(flagIcon)
```

Finally, we can also use the custom element constructor[p742] itself. That is, the above code is equivalent to:

```
const flagIcon = new FlagIcon()
flagIcon.country = "jp"
document.body.appendChild(flagIcon)
```

4.13.1.2 Creating a form-associated custom element §[p735]

This section is non-normative.

Adding a static `formAssociated` property, with a true value, makes an autonomous custom element[p742] a form-associated custom element[p743]. The `ElementInternals`[p754] interface helps you to implement functions and properties common to form control elements.

```
class MyCheckbox extends HTMLElement {
  static formAssociated = true;
  static observedAttributes = ['checked'];

  constructor() {
    super();
    this._internals = this.attachInternals();
    this.addEventListener('click', this._onClick.bind(this));
  }

  get form() { return this._internals.form; }
  get name() { return this.getAttribute('name'); }
  get type() { return this.localName; }

  get checked() { return this.hasAttribute('checked'); }
  set checked(flag) { this.toggleAttribute('checked', Boolean(flag)); }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "checked" due to observedAttributes
    this._internals.setFormValue(this.checked ? 'on' : null);
  }

  _onClick(event) {
```

```
    this.checked = !this.checked;
  }
}
customElements.define('my-checkbox', MyCheckbox);
```

You can use the custom element `my-checkbox` like a built-in form-associated element. For example, putting it in form[p505] or label[p509] associates the `my-checkbox` element with them, and submitting the form[p505] will send data provided by `my-checkbox` implementation.

```
<form action="..." method="...">
  <label><my-checkbox name="agreed"></my-checkbox> I read the agreement.</label>
  <input type="submit">
</form>
```

4.13.1.3 Creating a custom element with default accessible roles, states, and properties §[p73] 6

This section is non-normative.

By using the appropriate properties of ElementInternals[p754], your custom element can have default accessibility semantics. The following code expands our form-associated checkbox from the previous section to properly set its default role and checkedness, as viewed by accessibility technology:

```
class MyCheckbox extends HTMLElement {
  static formAssociated = true;
  static observedAttributes = ['checked'];

  constructor() {
    super();
    this._internals = this.attachInternals();
    this.addEventListener('click', this._onClick.bind(this));

    this._internals.role = 'checkbox';
    this._internals.ariaChecked = 'false';
  }

  get form() { return this._internals.form; }
  get name() { return this.getAttribute('name'); }
  get type() { return this.localName; }

  get checked() { return this.hasAttribute('checked'); }
  set checked(flag) { this.toggleAttribute('checked', Boolean(flag)); }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "checked" due to observedAttributes
    this._internals.setFormValue(this.checked ? 'on' : null);
    this._internals.ariaChecked = this.checked;
  }

  _onClick(event) {
    this.checked = !this.checked;
  }
}
customElements.define('my-checkbox', MyCheckbox);
```

Note that, like for built-in elements, these are only defaults, and can be overridden by the page author using the role[p67] and aria-*[p67] attributes:

```
<!-- This markup is non-conforming -->
<input type="checkbox" checked role="button" aria-checked="false">
```

```
<!-- This markup is probably not what the custom element author intended -->
<my-checkbox role="button" checked aria-checked="false">
```

Custom element authors are encouraged to state what aspects of their accessibility semantics are strong native semantics, i.e., should not be overridden by users of the custom element. In our example, the author of the `my-checkbox` element would state that its role and `aria-checked` values are strong native semantics, thus discouraging code such as the above.

4.13.1.4 Creating a customized built-in element §[p737]

This section is non-normative.

Customized built-in elements[p742] are a distinct kind of custom element[p742], which are defined slightly differently and used very differently compared to autonomous custom elements[p742]. They exist to allow reuse of behaviors from the existing elements of HTML, by extending those elements with new custom functionality. This is important since many of the existing behaviors of HTML elements can unfortunately not be duplicated by using purely autonomous custom elements[p742]. Instead, customized built-in elements[p742] allow the installation of custom construction behavior, lifecycle hooks, and prototype chain onto existing elements, essentially "mixing in" these capabilities on top of the already-existing element.

Customized built-in elements[p742] require a distinct syntax from autonomous custom elements[p742] because user agents and other software key off an element's local name in order to identify the element's semantics and behavior. That is, the concept of customized built-in elements[p742] building on top of existing behavior depends crucially on the extended elements retaining their original local name.

In this example, we'll be creating a customized built-in element[p742] named `plastic-button`, which behaves like a normal button but gets fancy animation effects added whenever you click on it. We start by defining a class, just like before, although this time we extend `HTMLButtonElement`[p557] instead of `HTMLElement`[p138]:

```
class PlasticButton extends HTMLButtonElement {
  constructor() {
    super();

    this.addEventListener("click", () => {
      // Draw some fancy animation effects!
    });
  }
}
```

When defining our custom element, we have to also specify the `extends` option:

```
customElements.define("plastic-button", PlasticButton, { extends: "button" });
```

In general, the name of the element being extended cannot be determined simply by looking at what element interface it extends, as many elements share the same interface (such as `q`[p261] and `blockquote`[p229] both sharing `HTMLQuoteElement`[p230]).

To construct our customized built-in element[p742] from parsed HTML source text, we use the `is`[p742] attribute on a `button`[p556] element:

```
<button is="plastic-button">Click Me!</button>
```

Trying to use a customized built-in element[p742] as an autonomous custom element[p742] will *not* work; that is, `<plastic-button>Click me?</plastic-button>` will simply create an `HTMLElement`[p138] with no special behavior.

If you need to create a customized built-in element programmatically, you can use the following form of `createElement()`:

```
const plasticButton = document.createElement("button", { is: "plastic-button" });
plasticButton.textContent = "Click me!";
```

And as before, the constructor will also work:

```
const plasticButton2 = new PlasticButton();
```

```
console.log(plasticButton2.localName);  // will output "button"
console.assert(plasticButton2 instanceof PlasticButton);
console.assert(plasticButton2 instanceof HTMLButtonElement);
```

Note that when creating a customized built-in element programmatically, the `is`[p742] attribute will not be present in the DOM, since it was not explicitly set. However, it will be added to the output when serializing[p1309]:

```
console.assert(!plasticButton.hasAttribute("is"));
console.log(plasticButton.outerHTML); // will output '<button is="plastic-button"></button>'
```

Regardless of how it is created, all of the ways in which `button`[p556] is special apply to such "plastic buttons" as well: their focus behavior, ability to participate in form submission[p619], the `disabled`[p591] attribute, and so on.

Customized built-in elements[p742] are designed to allow extension of existing HTML elements that have useful user-agent supplied behavior or APIs. As such, they can only extend existing HTML elements defined in this specification, and cannot extend legacy elements such as `bgsound`[p1362], `blink`[p1363], `isindex`[p1362], `keygen`[p1362], `multicol`[p1363], `nextid`[p1362], or `spacer`[p1363] that have been defined to use `HTMLUnknownElement`[p139] as their element interface.

One reason for this requirement is future-compatibility: if a customized built-in element[p742] was defined that extended a currently-unknown element, for example `combobox`, this would prevent this specification from defining a `combobox` element in the future, as consumers of the derived customized built-in element[p742] would have come to depend on their base element having no interesting user-agent-supplied behavior.

4.13.1.5 Drawbacks of autonomous custom elements §[p738]

This section is non-normative.

As specified below, and alluded to above, simply defining and using an element called `taco-button` does not mean that such elements represent[p138] buttons. That is, tools such as web browsers, search engines, or accessibility technology will not automatically treat the resulting element as a button just based on its defined name.

To convey the desired button semantics to a variety of users, while still using an autonomous custom element[p742], a number of techniques would need to be employed:

- The addition of the `tabindex`[p819] attribute would make the `taco-button` focusable[p817]. Note that if the `taco-button` were to become logically disabled, the `tabindex`[p819] attribute would need to be removed.
- The addition of an ARIA role and various ARIA states and properties helps convey semantics to accessibility technology. For example, setting the role to "`button`" will convey the semantics that this is a button, enabling users to successfully interact with the control using usual button-like interactions in their accessibility technology. Setting the `aria-label` property is necessary to give the button an accessible name, instead of having accessibility technology traverse its child text nodes and announce them. And setting the `aria-disabled` state to "`true`" when the button is logically disabled conveys to accessibility technology the button's disabled state.
- The addition of event handlers to handle commonly-expected button behaviors helps convey the semantics of the button to web browser users. In this case, the most relevant event handler would be one that proxies appropriate `keydown` events to become `click` events, so that you can activate the button both with keyboard and by clicking.
- In addition to any default visual styling provided for `taco-button` elements, the visual styling will also need to be updated to reflect changes in logical state, such as becoming disabled; that is, whatever style sheet has rules for `taco-button` will also need to have rules for `taco-button[disabled]`.

With these points in mind, a full-featured `taco-button` that took on the responsibility of conveying button semantics (including the ability to be disabled) might look something like this:

```
class TacoButton extends HTMLElement {
  static observedAttributes = ["disabled"];

  constructor() {
    super();
    this._internals = this.attachInternals();
```

```
    this._internals.role = "button";

    this.addEventListener("keydown", e => {
      if (e.code === "Enter" || e.code === "Space") {
        this.dispatchEvent(new PointerEvent("click", {
          bubbles: true,
          cancelable: true
        }));
      }
    });

    this.addEventListener("click", e => {
      if (this.disabled) {
        e.preventDefault();
        e.stopImmediatePropagation();
      }
    });

    this._observer = new MutationObserver(() => {
      this._internals.ariaLabel = this.textContent;
    });
  }

  connectedCallback() {
    this.setAttribute("tabindex", "0");

    this._observer.observe(this, {
      childList: true,
      characterData: true,
      subtree: true
    });
  }

  disconnectedCallback() {
    this._observer.disconnect();
  }

  get disabled() {
    return this.hasAttribute("disabled");
  }
  set disabled(flag) {
    this.toggleAttribute("disabled", Boolean(flag));
  }

  attributeChangedCallback(name, oldValue, newValue) {
    // name will always be "disabled" due to observedAttributes
    if (this.disabled) {
      this.removeAttribute("tabindex");
      this._internals.ariaDisabled = "true";
    } else {
      this.setAttribute("tabindex", "0");
      this._internals.ariaDisabled = "false";
    }
  }
}
```

Even with this rather-complicated element definition, the element is not a pleasure to use for consumers: it will be continually "sprouting" tabindex[p819] attributes of its own volition, and its choice of `tabindex="0"` focusability behavior may not match the button[p556] behavior on the current platform. This is because as of now there is no way to specify default focus behavior for custom elements, forcing the use of the tabindex[p819] attribute to do so (even though it is usually reserved for allowing the consumer to override default behavior).

In contrast, a simple customized built-in element[p742], as shown in the previous section, would automatically inherit the semantics and behavior of the button[p556] element, with no need to implement these behaviors manually. In general, for any elements with nontrivial behavior and semantics that build on top of existing elements of HTML, customized built-in elements[p742] will be easier to develop, maintain, and consume.

4.13.1.6 Upgrading elements after their creation §[p740]

This section is non-normative.

Because element definition[p745] can occur at any time, a non-custom element could be created, and then later become a custom element[p742] after an appropriate definition[p744] is registered. We call this process "upgrading" the element, from a normal element into a custom element.

Upgrades[p748] enable scenarios where it may be preferable for custom element definitions[p744] to be registered after relevant elements have been initially created, such as by the parser. They allow progressive enhancement of the content in the custom element. For example, in the following HTML document the element definition for `img-viewer` is loaded asynchronously:

```
<!DOCTYPE html>
<html lang="en">
<title>Image viewer example</title>

<img-viewer filter="Kelvin">
  <img src="images/tree.jpg" alt="A beautiful tree towering over an empty savannah">
</img-viewer>

<script src="js/elements/img-viewer.js" async></script>
```

The definition for the `img-viewer` element here is loaded using a script[p638] element marked with the async[p640] attribute, placed after the `<img-viewer>` tag in the markup. While the script is loading, the `img-viewer` element will be treated as an undefined element, similar to a span[p293]. Once the script loads, it will define the `img-viewer` element, and the existing `img-viewer` element on the page will be upgraded, applying the custom element's definition (which presumably includes applying an image filter identified by the string "Kelvin", enhancing the image's visual appearance).

Note that upgrades[p748] only apply to elements in the document tree. (Formally, elements that are connected.) An element that is not inserted into a document will stay un-upgraded. An example illustrates this point:

```
<!DOCTYPE html>
<html lang="en">
<title>Upgrade edge-cases example</title>

<example-element></example-element>

<script>
  "use strict";

  const inDocument = document.querySelector("example-element");
  const outOfDocument = document.createElement("example-element");

  // Before the element definition, both are HTMLElement:
  console.assert(inDocument instanceof HTMLElement);
  console.assert(outOfDocument instanceof HTMLElement);

  class ExampleElement extends HTMLElement {}
  customElements.define("example-element", ExampleElement);

  // After element definition, the in-document element was upgraded:
  console.assert(inDocument instanceof ExampleElement);
  console.assert(!(outOfDocument instanceof ExampleElement));
```

```
  document.body.appendChild(outOfDocument);

  // Now that we've moved the element into the document, it too was upgraded:
  console.assert(outOfDocument instanceof ExampleElement);
</script>
```

4.13.2 Requirements for custom element constructors and reactions §[p74 1]

When authoring custom element constructors[p742], authors are bound by the following conformance requirements:

- A parameter-less call to `super()` must be the first statement in the constructor body, to establish the correct prototype chain and **this** value before any further code is run.
- A `return` statement must not appear anywhere inside the constructor body, unless it is a simple early-return (`return` or `return this`).
- The constructor must not use the `document.write()`[p1099] or `document.open()`[p1098] methods.
- The element's attributes and children must not be inspected, as in the non-upgrade[p748] case none will be present, and relying on upgrades makes the element less usable.
- The element must not gain any attributes or children, as this violates the expectations of consumers who use the `createElement` or `createElementNS` methods.
- In general, work should be deferred to `connectedCallback` as much as possible—especially work involving fetching resources or rendering. However, note that `connectedCallback` can be called more than once, so any initialization work that is truly one-time will need a guard to prevent it from running twice.
- In general, the constructor should be used to set up initial state and default values, and to set up event listeners and possibly a shadow root.

Several of these requirements are checked during element creation, either directly or indirectly, and failing to follow them will result in a custom element that cannot be instantiated by the parser or DOM APIs. This is true even if the work is done inside a constructor-initiated microtask[p1072], as a microtask checkpoint[p1077] can occur immediately after construction.

When authoring custom element reactions[p751], authors should avoid manipulating the node tree as this can lead to unexpected results.

Example

An element's `connectedCallback` can be queued before the element is disconnected, but as the callback queue is still processed, it results in a `connectedCallback` for an element that is no longer connected:

```
class CParent extends HTMLElement {
  connectedCallback() {
    this.firstChild.remove();
  }
}
customElements.define("c-parent", CParent);

class CChild extends HTMLElement {
  connectedCallback() {
    console.log("CChild connectedCallback: isConnected =", this.isConnected);
  }
}
customElements.define("c-child", CChild);

const parent = new CParent(),
      child = new CChild();
parent.append(child);
document.body.append(parent);

// Logs:
```

```
// CChild connectedCallback: isConnected = false
```

4.13.3 Core concepts §[p742]

A **custom element** is an element that is custom. Informally, this means that its constructor and prototype are defined by the author, instead of by the user agent. This author-supplied constructor function is called the **custom element constructor**.

MDN

Two distinct types of custom elements[p742] can be defined:

1. An **autonomous custom element**, which is defined with no `extends` option. These types of custom elements have a local name equal to their defined name[p744].

2. A **customized built-in element**, which is defined with an `extends` option. These types of custom elements have a local name equal to the value passed in their `extends` option, and their defined name[p744] is used as the value of the **`is`** attribute, which therefore must be a valid custom element name[p743].

After a custom element[p742] is created, changing the value of the `is`[p742] attribute does not change the element's behavior, as it is saved on the element as its `is` value.

Autonomous custom elements[p742] have the following element definition:

Categories[p143]:

Flow content[p146].
Phrasing content[p146].
Palpable content[p147].
For form-associated custom elements[p743]: Listed[p505], labelable[p505], submittable[p505], and resettable[p505] form-associated element[p505].

Contexts in which this element can be used[p143]:

Where phrasing content[p146] is expected.

Content model[p143]:

Transparent[p148].

Content attributes[p143]:

Global attributes[p151], except the `is`[p742] attribute
`form`[p588], for form-associated custom elements[p743] — Associates the element with a `form`[p505] element
`disabled`[p591], for form-associated custom elements[p743] — Whether the form control is disabled
`readonly`[p743], for form-associated custom elements[p743] — Affects `willValidate`[p615], plus any behavior added by the custom element author
`name`[p589], for form-associated custom elements[p743] — Name of the element to use for form submission[p617] and in the `form.elements`[p507] API
Any other attribute that has no namespace (see prose).

Accessibility considerations[p143]:

For form-associated custom elements[p743]: for authors; for implementers.
Otherwise: for authors; for implementers.

DOM interface[p143]:

Supplied by the element's author (inherits from `HTMLElement`[p138])

An autonomous custom element[p742] does not have any special meaning: it represents[p138] its children. A customized built-in element[p742] inherits the semantics of the element that it extends.

Any namespace-less attribute that is relevant to the element's functioning, as determined by the element's author, may be specified on an autonomous custom element[p742], so long as the attribute name is XML-compatible[p45] and contains no ASCII upper alphas. The exception is the `is`[p742] attribute, which must not be specified on an autonomous custom element[p742] (and which will have no effect if it is).

Customized built-in elements[p742] follow the normal requirements for attributes, based on the elements they extend. To add custom

attribute-based behavior, use data-*[p160] attributes.

An autonomous custom element[p742] is called a **form-associated custom element** if the element is associated with a custom element definition[p744] whose form-associated[p744] field is set to true.

The name[p589] attribute represents the form-associated custom element[p743]'s name. The disabled[p591] attribute is used to make the form-associated custom element[p743] non-interactive and to prevent its submission value[p755] from being submitted. The form[p588] attribute is used to explicitly associate the form-associated custom element[p743] with its form owner[p588].

The **readonly** attribute of form-associated custom elements[p743] specifies that the element is barred from constraint validation[p612]. User agents don't provide any other behavior for the attribute, but custom element authors should, where possible, use its presence to make their control non-editable in some appropriate fashion, similar to the behavior for the readonly[p542] attribute on built-in form controls.

Constraint validation: If the readonly[p743] attribute is specified on a form-associated custom element[p743], the element is barred from constraint validation[p612].

The reset algorithm[p626] for form-associated custom elements[p743] is to enqueue a custom element callback reaction[p752] with the element, callback name "formResetCallback", and an empty argument list.

A **valid custom element name** is a sequence of characters *name* that meets all of the following requirements:

- *name* must match the PotentialCustomElementName[p743] production:

  PotentialCustomElementName **::=**
  [a-z] (PCENChar[p743])* '-' (PCENChar[p743])*

  PCENChar **::=**
  "-" | "." | [0-9] | "_" | [a-z] | #xB7 | [#xC0-#xD6] | [#xD8-#xF6] | [#xF8-#x37D] | [#x37F-#x1FFF] | [#x200C-#x200D] | [#x203F-#x2040] | [#x2070-#x218F] | [#x2C00-#x2FEF] | [#x3001-#xD7FF] | [#xF900-#xFDCF] | [#xFDF0-#xFFFD] | [#x10000-#xEFFFF]

  This uses the EBNF notation from the *XML* specification. [XML][p1419]

- *name* must not be any of the following:

  - annotation-xml
  - color-profile
  - font-face
  - font-face-src
  - font-face-uri
  - font-face-format
  - font-face-name
  - missing-glyph

  Note

  The list of names above is the summary of all hyphen-containing element names from the applicable specifications[p70], namely SVG 2 *and* MathML. *[SVG][p1417] [MATHML][p1414]*

Note

These requirements ensure a number of goals for valid custom element names[p743]:

- *They start with an ASCII lower alpha, ensuring that the HTML parser will treat them as tags instead of as text.*
- *They do not contain any ASCII upper alphas, ensuring that the user agent can always treat HTML elements ASCII-case-insensitively.*
- *They contain a hyphen, used for namespacing and to ensure forward compatibility (since no elements will be added to HTML, SVG, or MathML with hyphen-containing local names in the future).*
- *They can always be created with* `createElement()` *and* `createElementNS()`*, which have restrictions that go beyond the parser's.*

Apart from these restrictions, a large variety of names is allowed, to give maximum flexibility for use cases like `<math-α>` *or*

`<emotion-😍>`.

A **custom element definition** describes a custom element[p742] and consists of:

A *name*

A valid custom element name[p743]

A *local name*

A local name

A *constructor*

A Web IDL `CustomElementConstructor`[p745] callback function type value wrapping the custom element constructor[p742]

A list of *observed attributes*

A `sequence<DOMString>`

A collection of *lifecycle callbacks*

A map, whose keys are the strings "`connectedCallback`", "`disconnectedCallback`", "`adoptedCallback`", "`attributeChangedCallback`", "`formAssociatedCallback`", "`formDisabledCallback`", "`formResetCallback`", and "`formStateRestoreCallback`". The corresponding values are either a Web IDL `Function` callback function type value, or null. By default the value of each entry is null.

A *construction stack*

A list, initially empty, that is manipulated by the upgrade an element[p748] algorithm and the HTML element constructors[p140]. Each entry in the list will be either an element or an ***already constructed* marker**.

A *form-associated* boolean

If this is true, user agent treats elements associated to this custom element definition[p744] as form-associated custom elements[p743].

A *disable internals* boolean

Controls `attachInternals()`[p753].

A *disable shadow* boolean

Controls `attachShadow()`.

To **look up a custom element definition**, given a *document*, *namespace*, *localName*, and *is*, perform the following steps. They will return either a custom element definition[p744] or null:

1. If *namespace* is not the HTML namespace, return null.
2. If *document*'s browsing context[p961] is null, return null.
3. Let *registry* be *document*'s relevant global object[p1039]'s `CustomElementRegistry`[p745] object.
4. If there is custom element definition[p744] in *registry* with name[p744] and local name[p744] both equal to *localName*, return that custom element definition[p744].
5. If there is a custom element definition[p744] in *registry* with name[p744] equal to *is* and local name[p744] equal to *localName*, return that custom element definition[p744].
6. Return null.

4.13.4 The `CustomElementRegistry`[p745] interface §[p74 4]

MDN

Each `Window`[p892] object is associated with a unique instance of a `CustomElementRegistry`[p745] object, allocated when the `Window`[p892] object is created.

Note

Custom element registries are associated with `Window`[p892] objects, instead of `Document`[p127] objects, since each custom element constructor[p742] inherits from the `HTMLElement`[p138] interface, and there is exactly one `HTMLElement`[p138] interface per `Window`[p892] object.

MDN

The **customElements** attribute of the Window[p892] interface must return the CustomElementRegistry[p745] object for that Window[p892] object.

IDL
```
[Exposed=Window]
interface CustomElementRegistry {
  [CEReactions] undefined define(DOMString name, CustomElementConstructor constructor, optional
ElementDefinitionOptions options = {});
  (CustomElementConstructor or undefined) get(DOMString name);
  DOMString? getName(CustomElementConstructor constructor);
  Promise<CustomElementConstructor> whenDefined(DOMString name);
  [CEReactions] undefined upgrade(Node root);
};

callback CustomElementConstructor = HTMLElement ();

dictionary ElementDefinitionOptions {
  DOMString extends;
};
```

Every CustomElementRegistry[p745] has a set of custom element definitions[p744], initially empty. In general, algorithms in this specification look up elements in the registry by any of name[p744], local name[p744], or constructor[p744].

Every CustomElementRegistry[p745] also has an **element definition is running** flag which is used to prevent reentrant invocations of element definition[p745]. It is initially unset.

Every CustomElementRegistry[p745] also has a **when-defined promise map**, mapping valid custom element names[p743] to promises. It is used to implement the whenDefined()[p747] method.

For web developers (non-normative)

***window*.customElements[p745].define[p745](*name*, *constructor*)**

Defines a new custom element[p742], mapping the given name to the given constructor as an autonomous custom element[p742].

***window*.customElements[p745].define[p745](*name*, *constructor*, { extends: *baseLocalName* })**

Defines a new custom element[p742], mapping the given name to the given constructor as a customized built-in element[p742] for the element type[p45] identified by the supplied *baseLocalName*. A "NotSupportedError" DOMException will be thrown upon trying to extend a custom element[p742] or an unknown element.

***window*.customElements[p745].get[p747](*name*)**

Retrieves the custom element constructor[p742] defined for the given name[p744]. Returns undefined if there is no custom element definition[p744] with the given name[p744].

***window*.customElements[p745].getName[p747](*constructor*)**

Retrieves the given name for a custom element[p742] defined for the given constructor[p744]. Returns null if there is no custom element definition[p744] with the given constructor[p744].

***window*.customElements[p745].whenDefined[p747](*name*)**

Returns a promise that will be fulfilled with the custom element[p742]'s constructor when a custom element[p742] becomes defined with the given name. (If such a custom element[p742] is already defined, the returned promise will be immediately fulfilled.) Returns a promise rejected with a "SyntaxError" DOMException if not given a valid custom element name[p743].

***window*.customElements[p745].upgrade[p748](*root*)**

Tries to upgrade[p750] all shadow-including inclusive descendant elements of *root*, even if they are not connected.

Element definition is a process of adding a custom element definition[p744] to the CustomElementRegistry[p745]. This is accomplished by the define()[p745] method. When invoked, the **define(*name*, *constructor*, *options*)** method must run these steps:

1. If IsConstructor(*constructor*) is false, then throw a TypeError.
2. If *name* is not a valid custom element name[p743], then throw a "SyntaxError" DOMException.
3. If this CustomElementRegistry[p745] contains an entry with name[p744] *name*, then throw a "NotSupportedError" DOMException.

4. If this CustomElementRegistry[p745] contains an entry with constructor[p744] *constructor*, then throw a "NotSupportedError" DOMException.
5. Let *localName* be *name*.
6. Let *extends* be the value of the `extends` member of *options*, or null if no such member exists.
7. If *extends* is not null, then:
    1. If *extends* is a valid custom element name[p743], then throw a "NotSupportedError" DOMException.
    2. If the element interface for *extends* and the HTML namespace is HTMLUnknownElement[p139] (e.g., if *extends* does not indicate an element definition in this specification), then throw a "NotSupportedError" DOMException.
    3. Set *localName* to *extends*.
8. If this CustomElementRegistry[p745]'s element definition is running[p745] flag is set, then throw a "NotSupportedError" DOMException.
9. Set this CustomElementRegistry[p745]'s element definition is running[p745] flag.
10. Let *formAssociated* be false.
11. Let *disableInternals* be false.
12. Let *disableShadow* be false.
13. Let *observedAttributes* be an empty `sequence<DOMString>`.
14. Run the following substeps while catching any exceptions:
    1. Let *prototype* be ? Get(*constructor*, "prototype").
    2. If Type(*prototype*) is not Object, then throw a TypeError exception.
    3. Let *lifecycleCallbacks* be a map with the keys "`connectedCallback`", "`disconnectedCallback`", "`adoptedCallback`", and "`attributeChangedCallback`", each of which belongs to an entry whose value is null.
    4. For each of the keys *callbackName* in *lifecycleCallbacks*, in the order listed in the previous step:
        1. Let *callbackValue* be ? Get(*prototype*, *callbackName*).
        2. If *callbackValue* is not undefined, then set the value of the entry in *lifecycleCallbacks* with key *callbackName* to the result of converting *callbackValue* to the Web IDL Function callback type. Rethrow any exceptions from the conversion.
    5. If the value of the entry in *lifecycleCallbacks* with key "`attributeChangedCallback`" is not null, then:
        1. Let *observedAttributesIterable* be ? Get(*constructor*, "observedAttributes").
        2. If *observedAttributesIterable* is not undefined, then set *observedAttributes* to the result of converting *observedAttributesIterable* to a `sequence<DOMString>`. Rethrow any exceptions from the conversion.
    6. Let *disabledFeatures* be an empty `sequence<DOMString>`.
    7. Let *disabledFeaturesIterable* be ? Get(*constructor*, "disabledFeatures").
    8. If *disabledFeaturesIterable* is not undefined, then set *disabledFeatures* to the result of converting *disabledFeaturesIterable* to a `sequence<DOMString>`. Rethrow any exceptions from the conversion.
    9. Set *disableInternals* to true if *disabledFeatures* contains "`internals`".
    10. Set *disableShadow* to true if *disabledFeatures* contains "`shadow`".
    11. Let *formAssociatedValue* be ? Get(*constructor*, "formAssociated").
    12. Set *formAssociated* to the result of converting *formAssociatedValue* to a `boolean`. Rethrow any exceptions from the conversion.
    13. If *formAssociated* is true, for each of "`formAssociatedCallback`", "`formResetCallback`", "`formDisabledCallback`", and "`formStateRestoreCallback`" *callbackName*:

1. Let *callbackValue* be ? Get(*prototype*, *callbackName*).
2. If *callbackValue* is not undefined, then set the value of the entry in *lifecycleCallbacks* with key *callbackName* to the result of converting *callbackValue* to the Web IDL `Function` callback type. Rethrow any exceptions from the conversion.

Then, perform the following substep, regardless of whether the above steps threw an exception or not:

1. Unset this `CustomElementRegistry`[p745]'s element definition is running[p745] flag.

Finally, if the first set of substeps threw an exception, then rethrow that exception (thus terminating this algorithm). Otherwise, continue onward.

15. Let *definition* be a new custom element definition[p744] with name[p744] *name*, local name[p744] *localName*, constructor[p744] *constructor*, observed attributes[p744] *observedAttributes*, lifecycle callbacks[p744] *lifecycleCallbacks*, form-associated[p744] *formAssociated*, disable internals[p744] *disableInternals*, and disable shadow[p744] *disableShadow*.
16. Add *definition* to this `CustomElementRegistry`[p745].
17. Let *document* be this `CustomElementRegistry`[p745]'s relevant global object[p1039]'s associated `Document`[p894].
18. Let *upgrade candidates* be all elements that are shadow-including descendants of *document*, whose namespace is the HTML namespace and whose local name is *localName*, in shadow-including tree order. Additionally, if *extends* is non-null, only include elements whose `is` value is equal to *name*.
19. For each element *element* in *upgrade candidates*, enqueue a custom element upgrade reaction[p752] given *element* and *definition*.
20. If this `CustomElementRegistry`[p745]'s when-defined promise map[p745] contains an entry with key *name*:
    1. Let *promise* be the value of that entry.
    2. Resolve *promise* with *constructor*.
    3. Delete the entry with key *name* from this `CustomElementRegistry`[p745]'s when-defined promise map[p745].

When invoked, the **`get(name)`** method must run these steps:

1. If this `CustomElementRegistry`[p745] contains an entry with name[p744] *name*, then return that entry's constructor[p744].
2. Otherwise, return undefined.

The **`getName(constructor)`** method steps are:

MDN

1. If this `CustomElementRegistry`[p745] contains an entry with constructor[p744] *constructor*, then return that entry's name[p744].
2. Return null.

When invoked, the **`whenDefined(name)`** method must run these steps:

1. If *name* is not a valid custom element name[p743], then return a promise rejected with a `"SyntaxError"` `DOMException`.
2. If this `CustomElementRegistry`[p745] contains an entry with name[p744] *name*, then return a promise resolved with that entry's constructor[p744].
3. Let *map* be this `CustomElementRegistry`[p745]'s when-defined promise map[p745].
4. If *map* does not contain an entry with key *name*, create an entry in *map* with key *name* and whose value is a new promise.
5. Let *promise* be the value of the entry in *map* with key *name*.
6. Return *promise*.

Example

The `whenDefined()`[p747] method can be used to avoid performing an action until all appropriate custom elements[p742] are defined. In this example, we combine it with the `:defined`[p764] pseudo-class to hide a dynamically-loaded article's contents until we're sure that all of the autonomous custom elements[p742] it uses are defined.

```
articleContainer.hidden = true;

fetch(articleURL)
  .then(response => response.text())
  .then(text => {
    articleContainer.innerHTML = text;

    return Promise.all(
      [...articleContainer.querySelectorAll(":not(:defined)")]
        .map(el => customElements.whenDefined(el.localName))
    );
  })
  .then(() => {
    articleContainer.hidden = false;
  });
```

When invoked, the **`upgrade(root)`** method must run these steps:

1. Let *candidates* be a list of all of *root*'s shadow-including inclusive descendant elements, in shadow-including tree order.
2. For each *candidate* of *candidates*, try to upgrade[p750] *candidate*.

Example

The `upgrade()`[p748] method allows upgrading of elements at will. Normally elements are automatically upgraded when they become connected, but this method can be used if you need to upgrade before you're ready to connect the element.

```
const el = document.createElement("spider-man");

class SpiderMan extends HTMLElement {}
customElements.define("spider-man", SpiderMan);

console.assert(!(el instanceof SpiderMan)); // not yet upgraded

customElements.upgrade(el);
console.assert(el instanceof SpiderMan);    // upgraded!
```

4.13.5 Upgrades §[p748]

To **upgrade an element**, given as input a custom element definition[p744] *definition* and an element *element*, run the following steps:

1. If *element*'s custom element state is not "`undefined`" or "`uncustomized`", then return.

   Example

   One scenario where this can occur due to reentrant invocation of this algorithm, as in the following example:

```
<!DOCTYPE html>
<x-foo id="a"></x-foo>
<x-foo id="b"></x-foo>

<script>
// Defining enqueues upgrade reactions for both "a" and "b"
customElements.define("x-foo", class extends HTMLElement {
  constructor() {
    super();

    const b = document.querySelector("#b");
```

```
    b.remove();

    // While this constructor is running for "a", "b" is still
    // undefined, and so inserting it into the document will enqueue a
    // second upgrade reaction for "b" in addition to the one enqueued
    // by defining x-foo.
    document.body.appendChild(b);
  }
})
</script>
```

This step will thus bail out the algorithm early when upgrade an element[p748] is invoked with "b" a second time.

2. Set *element*'s custom element definition to *definition*.

3. Set *element*'s custom element state to "failed".

   Note

   It will be set to "custom" after the upgrade succeeds[p750]. For now, we set it to "failed" so that any reentrant invocations will hit the above early-exit step[p748].

4. For each *attribute* in *element*'s attribute list, in order, enqueue a custom element callback reaction[p752] with *element*, callback name "attributeChangedCallback", and an argument list containing *attribute*'s local name, null, *attribute*'s value, and *attribute*'s namespace.

5. If *element* is connected, then enqueue a custom element callback reaction[p752] with *element*, callback name "connectedCallback", and an empty argument list.

6. Add *element* to the end of *definition*'s construction stack[p744].

7. Let *C* be *definition*'s constructor[p744].

8. Run the following substeps while catching any exceptions:

   1. If *definition*'s disable shadow[p744] is true and *element*'s shadow root is non-null, then throw a "NotSupportedError" DOMException.

      Note

      This is needed as attachShadow() does not use look up a custom element definition[p744] while attachInternals()[p753] does.

   2. Set *element*'s custom element state to "precustomized".

   3. Let *constructResult* be the result of constructing *C*, with no arguments.

      Note

      If C non-conformantly[p741] uses an API decorated with the [CEReactions][p752] extended attribute, then the reactions enqueued at the beginning of this algorithm will execute during this step, before C finishes and control returns to this algorithm. Otherwise, they will execute after C and the rest of the upgrade process finishes.

   4. If SameValue(*constructResult*, *element*) is false, then throw a TypeError.

      Note

      This can occur if C constructs another instance of the same custom element before calling super(), or if C uses JavaScript's return-override feature to return an arbitrary HTMLElement[p138] object from the constructor.

   Then, perform the following substep, regardless of whether the above steps threw an exception or not:

   1. Remove the last entry from the end of *definition*'s construction stack[p744].

      Note

Assuming C *calls* `super()` *(as it will if it is conformant[p741]), and that the call succeeds, this will be the* already constructed *marker[p744] that replaced the* element *we pushed at the beginning of this algorithm. (The HTML element constructor[p140] carries out this replacement.)*

If C *does not call* `super()` *(i.e. it is not conformant[p741]), or if any step in the HTML element constructor[p140] throws, then this entry will still be* element*.*

Finally, if the above steps threw an exception, then:

1. Set *element*'s custom element definition to null.
2. Empty *element*'s custom element reaction queue[p751].
3. Rethrow the exception (thus terminating this algorithm).

Note

If the above steps threw an exception, then element*'s custom element state will remain* "`failed`" *or* "`precustomized`"*.*

9. If *element* is a form-associated custom element[p743], then:
   1. Reset the form owner[p588] of *element*. If *element* is associated with a `form`[p505] element, then enqueue a custom element callback reaction[p752] with *element*, callback name "`formAssociatedCallback`", and « the associated `form`[p505] ».
   2. If *element* is disabled[p592], then enqueue a custom element callback reaction[p752] with *element*, callback name "`formDisabledCallback`" and « true ».
10. Set *element*'s custom element state to "`custom`".

To **try to upgrade an element**, given as input an element *element*, run the following steps:

1. Let *definition* be the result of looking up a custom element definition[p744] given *element*'s node document, *element*'s namespace, *element*'s local name, and *element*'s `is` value.
2. If *definition* is not null, then enqueue a custom element upgrade reaction[p752] given *element* and *definition*.

4.13.6 Custom element reactions §[p750]

A custom element[p742] possesses the ability to respond to certain occurrences by running author code:

- When upgraded[p748], its constructor[p742] is run, with no arguments.
- When it becomes connected[p46], its `connectedCallback` is called, with no arguments.
- When it becomes disconnected[p46], its `disconnectedCallback` is called, with no arguments.
- When it is adopted into a new document, its `adoptedCallback` is called, given the old document and new document as arguments.
- When any of its attributes are changed, appended, removed, or replaced, its `attributeChangedCallback` is called, given the attribute's local name, old value, new value, and namespace as arguments. (An attribute's old or new value is considered to be null when the attribute is added or removed, respectively.)
- When the user agent resets the form owner[p588] of a form-associated custom element[p743] and doing so changes the form owner, its `formAssociatedCallback` is called, given the new form owner (or null if no owner) as an argument.
- When the form owner of a form-associated custom element[p743] is reset[p626], its `formResetCallback` is called.
- When the disabled[p592] state of a form-associated custom element[p743] is changed, its `formDisabledCallback` is called, given the new state as an argument.
- When user agent updates a form-associated custom element[p743]'s value on behalf of a user or as part of navigation[p1012], its `formStateRestoreCallback` is called, given the new state and a string indicating a reason, "`autocomplete`" or "`restore`", as arguments.

We call these reactions collectively **custom element reactions**.

The way in which custom element reactions[p751] are invoked is done with special care, to avoid running author code during the middle of delicate operations. Effectively, they are delayed until "just before returning to user script". This means that for most purposes they appear to execute synchronously, but in the case of complicated composite operations (like cloning, or range manipulation), they will instead be delayed until after all the relevant user agent processing steps have completed, and then run together as a batch.

Additionally, the precise ordering of these reactions is managed via a somewhat-complicated stack-of-queues system, described below. The intention behind this system is to guarantee that custom element reactions[p751] always are invoked in the same order as their triggering actions, at least within the local context of a single custom element[p742]. (Because custom element reaction[p751] code can perform its own mutations, it is not possible to give a global ordering guarantee across multiple elements.)

Each similar-origin window agent[p1028] has a **custom element reactions stack**, which is initially empty. A similar-origin window agent[p1028]'s **current element queue** is the element queue[p751] at the top of its custom element reactions stack[p751]. Each item in the stack is an **element queue**, which is initially empty as well. Each item in an element queue[p751] is an element. (The elements are not necessarily custom yet, since this queue is used for upgrades[p748] as well.)

Each custom element reactions stack[p751] has an associated **backup element queue**, which an initially-empty element queue[p751]. Elements are pushed onto the backup element queue[p751] during operations that affect the DOM without going through an API decorated with `[CEReactions]`[p752], or through the parser's create an element for the token[p1258] algorithm. An example of this is a user-initiated editing operation which modifies the descendants or attributes of an editable element. To prevent reentrancy when processing the backup element queue[p751], each custom element reactions stack[p751] also has a **processing the backup element queue** flag, initially unset.

All elements have an associated **custom element reaction queue**, initially empty. Each item in the custom element reaction queue[p751] is of one of two types:

- An **upgrade reaction**, which will upgrade[p748] the custom element and contains a custom element definition[p744]; or
- A **callback reaction**, which will call a lifecycle callback, and contains a callback function as well as a list of arguments.

This is all summarized in the following schematic diagram:

To **enqueue an element on the appropriate element queue**, given an element *element*, run the following steps:

1. Let *reactionsStack* be *element*'s relevant agent[p1029]'s custom element reactions stack[p751].

2. If *reactionsStack* is empty, then:
    1. Add *element* to *reactionsStack*'s backup element queue[p751].
    2. If *reactionsStack*'s processing the backup element queue[p751] flag is set, then return.
    3. Set *reactionsStack*'s processing the backup element queue[p751] flag.
    4. Queue a microtask[p1073] to perform the following steps:
        1. Invoke custom element reactions[p752] in *reactionsStack*'s backup element queue[p751].
        2. Unset *reactionsStack*'s processing the backup element queue[p751] flag.
3. Otherwise, add *element* to *element*'s relevant agent[p1029]'s current element queue[p751].

To **enqueue a custom element callback reaction**, given a custom element[p742] *element*, a callback name *callbackName*, and a list of arguments *args*, run the following steps:

1. Let *definition* be *element*'s custom element definition.
2. Let *callback* be the value of the entry in *definition*'s lifecycle callbacks[p744] with key *callbackName*.
3. If *callback* is null, then return.
4. If *callbackName* is "`attributeChangedCallback`", then:
    1. Let *attributeName* be the first element of *args*.
    2. If *definition*'s observed attributes[p744] does not contain *attributeName*, then return.
5. Add a new callback reaction[p751] to *element*'s custom element reaction queue[p751], with callback function *callback* and arguments *args*.
6. Enqueue an element on the appropriate element queue[p751] given *element*.

To **enqueue a custom element upgrade reaction**, given an element *element* and custom element definition[p744] *definition*, run the following steps:

1. Add a new upgrade reaction[p751] to *element*'s custom element reaction queue[p751], with custom element definition[p744] *definition*.
2. Enqueue an element on the appropriate element queue[p751] given *element*.

To **invoke custom element reactions** in an element queue[p751] *queue*, run the following steps:

1. While *queue* is not empty:
    1. Let *element* be the result of dequeuing from *queue*.
    2. Let *reactions* be *element*'s custom element reaction queue[p751].
    3. Repeat until *reactions* is empty:
        1. Remove the first element of *reactions*, and let *reaction* be that element. Switch on *reaction*'s type:

        ↪ **upgrade reaction[p751]**

        Upgrade[p748] *element* using *reaction*'s custom element definition[p744].

        ↪ **callback reaction[p751]**

        Invoke *reaction*'s callback function with *reaction*'s arguments, and with *element* as the callback this value.

        If this throws an exception, catch it, and report the exception[p1053].

To ensure custom element reactions[p751] are triggered appropriately, we introduce the **`[CEReactions]`** IDL extended attribute. It indicates that the relevant algorithm is to be supplemented with additional steps in order to appropriately track and invoke custom element reactions[p751].

The [CEReactions] extended attribute must take no arguments, and must not appear on anything other than an operation, attribute, setter, or deleter. Additionally, it must not appear on readonly attributes.

Operations, attributes, setters, or deleters annotated with the [CEReactions] extended attribute must run the following steps in place of the ones specified in their description:

1. Push a new element queue onto this object's relevant agent's custom element reactions stack.
2. Run the originally-specified steps for this construct, catching any exceptions. If the steps return a value, let *value* be the returned value. If they throw an exception, let *exception* be the thrown exception.
3. Let *queue* be the result of popping from this object's relevant agent's custom element reactions stack.
4. Invoke custom element reactions in *queue*.
5. If an exception *exception* was thrown by the original steps, rethrow *exception*.
6. If a value *value* was returned from the original steps, return *value*.

Note

The intent behind this extended attribute is somewhat subtle. One way of accomplishing its goals would be to say that every operation, attribute, setter, and deleter on the platform must have these steps inserted, and to allow implementers to optimize away unnecessary cases (where no DOM mutation is possible that could cause custom element reactions to occur).

However, in practice this imprecision could lead to non-interoperable implementations of custom element reactions, as some implementations might forget to invoke these steps in some cases. Instead, we settled on the approach of explicitly annotating all relevant IDL constructs, as a way of ensuring interoperable behavior and helping implementations easily pinpoint all cases where these steps are necessary.

Any nonstandard APIs introduced by the user agent that could modify the DOM in such a way as to cause enqueuing a custom element callback reaction or enqueuing a custom element upgrade reaction, for example by modifying any attributes or child elements, must also be decorated with the [CEReactions] attribute.

Note

As of the time of this writing, the following nonstandard or not-yet-standardized APIs are known to fall into this category:

- HTMLInputElement's `webkitdirectory` *and* `incremental` *IDL attributes*
- HTMLLinkElement's `scope` *IDL attribute*

4.13.7 Element internals §

Certain capabilities are meant to be available to a custom element author, but not to a custom element consumer. These are provided by the `element.attachInternals()` method, which returns an instance of ElementInternals. The properties and methods of ElementInternals allow control over internal features which the user agent provides to all elements.

For web developers (non-normative)

***element*.attachInternals()**

Returns an ElementInternals object targeting the custom element *element*. Throws an exception if *element* is not a custom element, if the "`internals`" feature was disabled as part of the element definition, or if it is called twice on the same element.

MDN

Each HTMLElement has an **attached internals** (null or an ElementInternals object), initially null.

The **`attachInternals()`** method steps are:

1. If this's `is` value is not null, then throw a "`NotSupportedError`" `DOMException`.
2. Let *definition* be the result of looking up a custom element definition given this's node document, its namespace, its local name, and null as the `is` value.

3. If *definition* is null, then throw an "NotSupportedError" DOMException.
4. If *definition*'s disable internals[p744] is true, then throw a "NotSupportedError" DOMException.
5. If this's attached internals[p753] is non-null, then throw an "NotSupportedError" DOMException.
6. If this's custom element state is not "precustomized" or "custom", then throw a "NotSupportedError" DOMException.
7. Set this's attached internals[p753] to a new ElementInternals[p754] instance whose target element[p754] is this.
8. Return this's attached internals[p753].

4.13.7.1 The ElementInternals[p754] interface §[p754]

The IDL for the ElementInternals[p754] interface is as follows, with the various operations and attributes defined in the following sections:

IDL
```
[Exposed=Window]
interface ElementInternals {
  // Shadow root access
  readonly attribute ShadowRoot? shadowRoot;

  // Form-associated custom elements
  undefined setFormValue((File or USVString or FormData)? value,
                         optional (File or USVString or FormData)? state);

  readonly attribute HTMLFormElement? form;

  undefined setValidity(optional ValidityStateFlags flags = {},
                        optional DOMString message,
                        optional HTMLElement anchor);
  readonly attribute boolean willValidate;
  readonly attribute ValidityState validity;
  readonly attribute DOMString validationMessage;
  boolean checkValidity();
  boolean reportValidity();

  readonly attribute NodeList labels;
};

// Accessibility semantics
ElementInternals includes ARIAMixin;

dictionary ValidityStateFlags {
  boolean valueMissing = false;
  boolean typeMismatch = false;
  boolean patternMismatch = false;
  boolean tooLong = false;
  boolean tooShort = false;
  boolean rangeUnderflow = false;
  boolean rangeOverflow = false;
  boolean stepMismatch = false;
  boolean badInput = false;
  boolean customError = false;
};
```

Each ElementInternals[p754] has a **target element**, which is a custom element[p742].

4.13.7.2 Shadow root access §[p755]

For web developers (non-normative)

***internals*.shadowRoot**[p755]

Returns the ShadowRoot for *internals*'s target element[p754], if the target element[p754] is a shadow host, or null otherwise.

The **shadowRoot** getter steps are:

✔ MDN

1. Let *target* be this's target element[p754].
2. If *target* is not a shadow host, then return null.
3. Let *shadow* be *target*'s shadow root.
4. If *shadow*'s available to element internals is false, then return null.
5. Return *shadow*.

4.13.7.3 Form-associated custom elements §[p755]

For web developers (non-normative)

***internals*.setFormValue**[p756]**(*value*)**

Sets both the state[p756] and submission value[p755] of *internals*'s target element[p754] to *value*.

If *value* is null, the element won't participate in form submission.

***internals*.setFormValue**[p756]**(*value*, *state*)**

Sets the submission value[p755] of *internals*'s target element[p754] to *value*, and its state[p756] to *state*.

If *value* is null, the element won't participate in form submission.

***internals*.form**[p589]

Returns the form owner[p588] of *internals*'s target element[p754].

***internals*.setValidity**[p756]**(*flags*, *message* [, *anchor*])**

Marks *internals*'s target element[p754] as suffering from the constraints indicated by the *flags* argument, and sets the element's validation message to *message*. If *anchor* is specified, the user agent might use it to indicate problems with the constraints of *internals*'s target element[p754] when the form owner[p588] is validated interactively or reportValidity()[p617] is called.

***internals*.setValidity**[p756]**({})**

Marks *internals*'s target element[p754] as satisfying its constraints[p613].

***internals*.willValidate**[p615]

Returns true if *internals*'s target element[p754] will be validated when the form is submitted; false otherwise.

***internals*.validity**[p615]

Returns the ValidityState[p616] object for *internals*'s target element[p754].

***internals*.validationMessage**[p757]

Returns the error message that would be shown to the user if *internals*'s target element[p754] was to be checked for validity.

***valid* = *internals*.checkValidity()**[p617]

Returns true if *internals*'s target element[p754] has no validity problems; false otherwise. Fires an invalid[p1407] event at the element in the latter case.

***valid* = *internals*.reportValidity()**[p617]

Returns true if *internals*'s target element[p754] has no validity problems; otherwise, returns false, fires an invalid[p1407] event at the element, and (if the event isn't canceled) reports the problem to the user.

***internals*.labels**[p511]

Returns a NodeList of all the label[p509] elements that *internals*'s target element[p754] is associated with.

Each form-associated custom element[p743] has **submission value**. It is used to provide one or more entries[p622] on form submission. The initial value of submission value[p755] is null, and submission value[p755] can be null, a string, a File, or a list of entries[p622].

Each form-associated custom element[p743] has **state**. It is information with which the user agent can restore a user's input for the element. The initial value of state[p756] is null, and state[p756] can be null, a string, a `File`, or a list of entries[p622].

The `setFormValue()`[p756] method is used by the custom element author to set the element's submission value[p755] and state[p756], thus communicating these to the user agent.

When the user agent believes it is a good idea to restore a form-associated custom element[p743]'s state[p756], for example after navigation[p1012] or restarting the user agent, they may enqueue a custom element callback reaction[p752] with that element, callback name "`formStateRestoreCallback`", an argument list containing the state to be restored, and "`restore`".

If the user agent has a form-filling assist feature, then when the feature is invoked, it may enqueue a custom element callback reaction[p752] with a form-associated custom element[p743], callback name "`formStateRestoreCallback`", an argument list containing the state value determined by history of state value and some heuristics, and "`autocomplete`".

In general, the state[p756] is information specified by a user, and the submission value[p755] is a value after canonicalization or sanitization, suitable for submission to the server. The following examples makes this concrete:

Example

Suppose that we have a form-associated custom element[p743] which asks a user to specify a date. The user specifies "`3/15/2019`", but the control wishes to submit "`2019-03-15`" to the server. "`3/15/2019`" would be a state[p756] of the element, and "`2019-03-15`" would be a submission value[p755].

Example

Suppose you develop a custom element emulating a the behavior of the existing checkbox[p533] `input`[p512] type. Its submission value[p755] would be the value of its `value` content attribute, or the string "`on`". Its state[p756] would be one of "`checked`", "`unchecked`", "`checked/indeterminate`", or "`unchecked/indeterminate`".

The **`setFormValue(value, state)`** method steps are:

1. Let *element* be this's target element[p754].
2. If *element* is not a form-associated custom element[p743], then throw a "`NotSupportedError`" `DOMException`.
3. Set target element[p754]'s submission value[p755] to *value* if *value* is not a `FormData` object, or to a clone of *value*'s entry list otherwise.
4. If the *state* argument of the function is omitted, set *element*'s state[p756] to its submission value[p755].
5. Otherwise, if *state* is a `FormData` object, set *element*'s state[p756] to a clone of *state*'s entry list.
6. Otherwise, set *element*'s state[p756] to *state*.

Each form-associated custom element[p743] has validity flags named `valueMissing`, `typeMismatch`, `patternMismatch`, `tooLong`, `tooShort`, `rangeUnderflow`, `rangeOverflow`, `stepMismatch`, and `customError`. They are false initially.

Each form-associated custom element[p743] has a **validation message** string. It is the empty string initially.

Each form-associated custom element[p743] has a **validation anchor** element. It is null initially.

The **`setValidity(flags, message, anchor)`** method steps are:

1. Let *element* be this's target element[p754].
2. If *element* is not a form-associated custom element[p743], then throw a "`NotSupportedError`" `DOMException`.
3. If *flags* contains one or more true values and *message* is not given or is the empty string, then throw a `TypeError`.
4. For each entry *flag* → *value* of *flags*, set *element*'s validity flag with the name *flag* to *value*.
5. Set *element*'s validation message[p756] to the empty string if *message* is not given or all of *element*'s validity flags are false, or to *message* otherwise.
6. If *element*'s `customError` validity flag is true, then set *element*'s custom validity error message[p612] to *element*'s validation message[p756]. Otherwise, set *element*'s custom validity error message[p612] to the empty string.

7. Set *element*'s validation anchor[p756] to null if *anchor* is not given. Otherwise, if *anchor* is not a shadow-including descendant of *element*, then throw a "NotFoundError" DOMException. Otherwise, set *element*'s validation anchor[p756] to *anchor*.

The **validationMessage** getter steps are:

1. Let *element* be this's target element[p754].
2. If *element* is not a form-associated custom element[p743], then throw a "NotSupportedError" DOMException.
3. Return *element*'s validation message[p756].

The **entry construction algorithm** for a form-associated custom element[p743], given an element *element* and an entry list[p622] *entry list*, consists of the following steps:

1. If *element*'s submission value[p755] is a list of entries[p622], then append each item of *element*'s submission value[p755] to *entry list*, and return.

   Note

   In this case, user agent does not refer to the name[p589] content attribute value. An implementation of form-associated custom element[p743] is responsible to decide names of entries[p622]. They can be the name[p589] content attribute value, they can be strings based on the name[p589] content attribute value, or they can be unrelated to the name[p589] content attribute.

2. If the element does not have a name[p589] attribute specified, or its name[p589] attribute's value is the empty string, then return.
3. If the element's submission value[p755] is not null, create an entry[p622] with the name[p589] attribute value and the submission value[p755], and append it to *entry list*.

4.13.7.4 Accessibility semantics §[p757]

For web developers (non-normative)

***internals*.role[p0] [= *value*]**

Sets or retrieves the default ARIA role for *internals*'s target element[p754], which will be used unless the page author overrides it using the role[p67] attribute.

***internals*.aria*[p0] [= *value*]**

Sets or retrieves various default ARIA states or property values for *internals*'s target element[p754], which will be used unless the page author overrides them using the aria-*[p67] attributes.

Each custom element[p742] has an **internal content attribute map**, which is a map, initially empty. See the Requirements related to ARIA and to platform accessibility APIs[p166] section for information on how this impacts platform accessibility APIs.

4.14 Common idioms without dedicated elements §[p757]

4.14.1 Breadcrumb navigation §[p757]

This specification does not provide a machine-readable way of describing breadcrumb navigation menus. Authors are encouraged to just use a series of links in a paragraph. The nav[p206] element can be used to mark the section containing these paragraphs as being navigation blocks.

Example

In the following example, the current page can be reached via two paths.

```
<nav>
 <p>
  <a href="/">Main</a> ▸
  <a href="/products/">Products</a> ▸
  <a href="/products/dishwashers/">Dishwashers</a> ▸
```

```
  <a>Second hand</a>
 </p>
 <p>
  <a href="/">Main</a> ▸
  <a href="/second-hand/">Second hand</a> ▸
  <a>Dishwashers</a>
 </p>
</nav>
```

4.14.2 Tag clouds §[p75] 8

This specification does not define any markup specifically for marking up lists of keywords that apply to a group of pages (also known as *tag clouds*). In general, authors are encouraged to either mark up such lists using `ul`[p234] elements with explicit inline counts that are then hidden and turned into a presentational effect using a style sheet, or to use SVG.

Example

Here, three tags are included in a short tag cloud:

```
<style>
.tag-cloud > li > span { display: none; }
.tag-cloud > li { display: inline; }
.tag-cloud-1 { font-size: 0.7em; }
.tag-cloud-2 { font-size: 0.9em; }
.tag-cloud-3 { font-size: 1.1em; }
.tag-cloud-4 { font-size: 1.3em; }
.tag-cloud-5 { font-size: 1.5em; }

@media speech {
  .tag-cloud > li > span { display:inline }
}
</style>
...
<ul class="tag-cloud">
 <li class="tag-cloud-4"><a title="28 instances" href="/t/apple">apple</a> <span>(popular)</span>
 <li class="tag-cloud-2"><a title="6 instances"  href="/t/kiwi">kiwi</a> <span>(rare)</span>
 <li class="tag-cloud-5"><a title="41 instances" href="/t/pear">pear</a> <span>(very
popular)</span>
</ul>
```

The actual frequency of each tag is given using the `title`[p154] attribute. A CSS style sheet is provided to convert the markup into a cloud of differently-sized words, but for user agents that do not support CSS or are not visual, the markup contains annotations like "(popular)" or "(rare)" to categorize the various tags by frequency, thus enabling all users to benefit from the information.

The `ul`[p234] element is used (rather than `ol`[p232]) because the order is not particularly important: while the list is in fact ordered alphabetically, it would convey the same information if ordered by, say, the length of the tag.

The `tag`[p326] `rel`[p297]-keyword is *not* used on these `a`[p252] elements because they do not represent tags that apply to the page itself; they are just part of an index listing the tags themselves.

4.14.3 Conversations §[p75] 8

This specification does not define a specific element for marking up conversations, meeting minutes, chat transcripts, dialogues in screenplays, instant message logs, and other situations where different players take turns in discourse.

Instead, authors are encouraged to mark up conversations using `p`[p223] elements and punctuation. Authors who need to mark the

speaker for styling purposes are encouraged to use span[p293] or b[p287]. Paragraphs with their text wrapped in the i[p286] element can be used for marking up stage directions.

Example

This example demonstrates this using an extract from Abbot and Costello's famous sketch, *Who's on first*:

```
<p> Costello: Look, you gotta first baseman?
<p> Abbott: Certainly.
<p> Costello: Who's playing first?
<p> Abbott: That's right.
<p> Costello becomes exasperated.
<p> Costello: When you pay off the first baseman every month, who gets the money?
<p> Abbott: Every dollar of it.
```

Example

The following extract shows how an IM conversation log could be marked up, using the data[p273] element to provide Unix timestamps for each line. Note that the timestamps are provided in a format that the time[p274] element does not support, so the data[p273] element is used instead (namely, Unix `time_t` timestamps). Had the author wished to mark up the data using one of the date and time formats supported by the time[p274] element, that element could have been used instead of data[p273]. This could be advantageous as it would allow data analysis tools to detect the timestamps unambiguously, without coordination with the page author.

```
<p> <data value="1319898155">14:22</data> <b>egof</b> I'm not that nerdy, I've only seen 30% of the
star trek episodes
<p> <data value="1319898192">14:23</data> <b>kaj</b> if you know what percentage of the star trek
episodes you have seen, you are inarguably nerdy
<p> <data value="1319898200">14:23</data> <b>egof</b> it's unarguably
<p> <data value="1319898228">14:23</data> <i>* kaj blinks</i>
<p> <data value="1319898260">14:24</data> <b>kaj</b> you are not helping your case
```

Example

HTML does not have a good way to mark up graphs, so descriptions of interactive conversations from games are more difficult to mark up. This example shows one possible convention using dl[p238] elements to list the possible responses at each point in the conversation. Another option to consider is describing the conversation in the form of a DOT file, and outputting the result as an SVG image to place in the document. [DOT][p1413]

```
<p> Next, you meet a fisher. You can say one of several greetings:
<dl>
 <dt> "Hello there!"
 <dd>
  <p> She responds with "Hello, how may I help you?"; you can respond with:
  <dl>
   <dt> "I would like to buy a fish."
   <dd> <p> She sells you a fish and the conversation finishes.
   <dt> "Can I borrow your boat?"
   <dd>
    <p> She is surprised and asks "What are you offering in return?".
    <dl>
     <dt> "Five gold." (if you have enough)
     <dt> "Ten gold." (if you have enough)
     <dt> "Fifteen gold." (if you have enough)
     <dd> <p> She lends you her boat. The conversation ends.
     <dt> "A fish." (if you have one)
     <dt> "A newspaper." (if you have one)
     <dt> "A pebble." (if you have one)
     <dd> <p> "No thanks", she replies. Your conversation options
     at this point are the same as they were after asking to borrow
     her boat, minus any options you've suggested before.
    </dl>
```

```
    </dd>
   </dl>
  </dd>
  <dt> "Vote for me in the next election!"
  <dd> <p> She turns away. The conversation finishes.
  <dt> "Madam, are you aware that your fish are running away?"
  <dd>
   <p> She looks at you skeptically and says "Fish cannot run, miss".
   <dl>
    <dt> "You got me!"
    <dd> <p> The fisher sighs and the conversation ends.
    <dt> "Only kidding."
    <dd> <p> "Good one!" she retorts. Your conversation options at this
    point are the same as those following "Hello there!" above.
    <dt> "Oh, then what are they doing?"
    <dd> <p> She looks at her fish, giving you an opportunity to steal
    her boat, which you do. The conversation ends.
   </dl>
  </dd>
 </dl>
```

Example

In some games, conversations are simpler: each character merely has a fixed set of lines that they say. In this example, a game FAQ/walkthrough lists some of the known possible responses for each character:

```
<section>
 <h1>Dialogue</h1>
 <p><small>Some characters repeat their lines in order each time you interact
 with them, others randomly pick from amongst their lines. Those who respond in
 order have numbered entries in the lists below.</small>
 <h2>The Shopkeeper</h2>
 <ul>
  <li>How may I help you?
  <li>Fresh apples!
  <li>A loaf of bread for madam?
 </ul>
 <h2>The pilot</h2>
 <p>Before the accident:
 <ul>
  <li>I'm about to fly out, sorry!
  <li>Sorry, I'm just waiting for flight clearance and then I'll be off!
 </ul>
 <p>After the accident:
 <ol>
  <li>I'm about to fly out, sorry!
  <li>Ok, I'm not leaving right now, my plane is being cleaned.
  <li>Ok, it's not being cleaned, it needs a minor repair first.
  <li>Ok, ok, stop bothering me! Truth is, I had a crash.
 </ol>
 <h2>Clan Leader</h2>
 <p>During the first clan meeting:
 <ul>
  <li>Hey, have you seen my daughter? I bet she's up to something nefarious again...
  <li>Nice weather we're having today, eh?
  <li>The name is Bailey, Jeff Bailey. How can I help you today?
  <li>A glass of water? Fresh from the well!
 </ul>
 <p>After the earthquake:
 <ol>
```

```
  <li>Everyone is safe in the shelter, we just have to put out the fire!
  <li>I'll go and tell the fire brigade, you keep hosing it down!
 </ol>
</section>
```

4.14.4 Footnotes §[p76] [1]

HTML does not have a dedicated mechanism for marking up footnotes. Here are the suggested alternatives.

For short inline annotations, the `title`[p154] attribute could be used.

Example

In this example, two parts of a dialogue are annotated with footnote-like content using the `title`[p154] attribute.

```
<p> <b>Customer</b>: Hello! I wish to register a complaint. Hello. Miss?
<p> <b>Shopkeeper</b>: <span title="Colloquial pronunciation of 'What do you'"
>Watcha</span> mean, miss?
<p> <b>Customer</b>: Uh, I'm sorry, I have a cold. I wish to make a complaint.
<p> <b>Shopkeeper</b>: Sorry, <span title="This is, of course, a lie.">we're
closing for lunch</span>.
```

Note

Unfortunately, relying on the `title`[p154] attribute is currently discouraged as many user agents do not expose the attribute in an accessible manner as required by this specification (e.g. requiring a pointing device such as a mouse to cause a tooltip to appear, which excludes keyboard-only users and touch-only users, such as anyone with a modern phone or tablet).

Note

If the `title`[p154] attribute is used, CSS can be used to draw the reader's attention to the elements with the attribute.

Example

For example, the following CSS places a dashed line below elements that have a `title`[p154] attribute.

```
CSS [title] { border-bottom: thin dashed; }
```

For longer annotations, the `a`[p252] element should be used, pointing to an element later in the document. The convention is that the contents of the link be a number in square brackets.

Example

In this example, a footnote in the dialogue links to a paragraph below the dialogue. The paragraph then reciprocally links back to the dialogue, allowing the user to return to the location of the footnote.

```
<p> Announcer: Number 16: The <i>hand</i>.
<p> Interviewer: Good evening. I have with me in the studio tonight
Mr Norman St John Polevaulter, who for the past few years has been
contradicting people. Mr Polevaulter, why <em>do</em> you
contradict people?
<p> Norman: I don't. <sup><a href="#fn1" id="r1">[1]</a></sup>
<p> Interviewer: You told me you did!
...
<section>
```

```
 <p id="fn1"><a href="#r1">[1]</a> This is, naturally, a lie,
 but paradoxically if it were true he could not say so without
 contradicting the interviewer and thus making it false.</p>
</section>
```

For side notes, longer annotations that apply to entire sections of the text rather than just specific words or sentences, the aside[p209] element should be used.

Example

In this example, a sidebar is given after a dialogue, giving it some context.

```
<p> <span class="speaker">Customer</span>: I will not buy this record, it is scratched.
<p> <span class="speaker">Shopkeeper</span>: I'm sorry?
<p> <span class="speaker">Customer</span>: I will not buy this record, it is scratched.
<p> <span class="speaker">Shopkeeper</span>: No no no, this's'a tobacconist's.
<aside>
 <p>In 1970, the British Empire lay in ruins, and foreign
 nationalists frequented the streets — many of them Hungarians
 (not the streets — the foreign nationals). Sadly, Alexander
 Yalt has been publishing incompetently-written phrase books.
</aside>
```

For figures or tables, footnotes can be included in the relevant figcaption[p247] or caption[p477] element, or in surrounding prose.

Example

In this example, a table has cells with footnotes that are given in prose. A figure[p244] element is used to give a single legend to the combination of the table and its footnotes.

```
<figure>
 <figcaption>Table 1. Alternative activities for knights.</figcaption>
 <table>
  <tr>
   <th> Activity
   <th> Location
   <th> Cost
  <tr>
   <td> Dance
   <td> Wherever possible
   <td> £0<sup><a href="#fn1">1</a></sup>
  <tr>
   <td> Routines, chorus scenes<sup><a href="#fn2">2</a></sup>
   <td> Undisclosed
   <td> Undisclosed
  <tr>
   <td> Dining<sup><a href="#fn3">3</a></sup>
   <td> Camelot
   <td> Cost of ham, jam, and spam<sup><a href="#fn4">4</a></sup>
 </table>
 <p id="fn1">1. Assumed.</p>
 <p id="fn2">2. Footwork impeccable.</p>
 <p id="fn3">3. Quality described as "well".</p>
 <p id="fn4">4. A lot.</p>
</figure>
```

4.15 Disabled elements §p763

An element is said to be **actually disabled** if it is one of the following:

- a `button`p556 element that is disabledp592
- an `input`p512 element that is disabledp592
- a `select`p559 element that is disabledp592
- a `textarea`p570 element that is disabledp592
- an `optgroup`p566 element that has a `disabled`p566 attribute
- an `option`p567 element that is disabledp568
- a `fieldset`p584 element that is a disabled fieldsetp584
- a form-associated custom elementp743 that is disabledp592

Note

This definition is used to determine what elements are focusablep817 and which elements match the `:enabled`p766 and `:disabled`p766 pseudo classes.

4.16 Matching HTML elements using selectors and CSS §p763

4.16.1 Case-sensitivity of the CSS 'attr()' function §p763

CSS Values and Units leaves the case-sensitivity of attribute names for the purpose of the 'attr()' function to be defined by the host language. [CSSVALUES]p1412

When comparing the attribute name part of a CSS 'attr()' function to the names of namespace-less attributes on HTML elementsp45 in HTML documents, the name part of the CSS 'attr()' function must first be converted to ASCII lowercase. The same function when compared to other attributes must be compared according to its original case. In both cases, to match the values must be identical to each other (and therefore the comparison is case sensitive).

Note

This is the same as comparing the name part of a CSS attribute selector, specified in the next section.

4.16.2 Case-sensitivity of selectors §p763

Selectors leaves the case-sensitivity of element names, attribute names, and attribute values to be defined by the host language. [SELECTORS]p1417

When comparing a CSS element type selector to the names of HTML elementsp45 in HTML documents, the CSS element type selector must first be converted to ASCII lowercase. The same selector when compared to other elements must be compared according to its original case. In both cases, to match the values must be identical to each other (and therefore the comparison is case sensitive).

When comparing the name part of a CSS attribute selector to the names of attributes on HTML elementsp45 in HTML documents, the name part of the CSS attribute selector must first be converted to ASCII lowercase. The same selector when compared to other attributes must be compared according to its original case. In both cases, the comparison is case-sensitive.

Attribute selectors on an HTML elementp45 in an HTML document must treat the *values* of attributes with the following names as ASCII case-insensitive:

- `accept`
- `accept-charset`
- `align`
- `alink`
- `axis`
- `bgcolor`

- charset
- checked
- clear
- codetype
- color
- compact
- declare
- defer
- dir
- direction
- disabled
- enctype
- face
- frame
- hreflang
- http-equiv
- lang
- language
- link
- media
- method
- multiple
- nohref
- noresize
- noshade
- nowrap
- readonly
- rel
- rev
- rules
- scope
- scrolling
- selected
- shape
- target
- text
- type
- valign
- valuetype
- vlink

Example

For example, the selector `[bgcolor="#ffffff"]` will match any HTML element with a `bgcolor` attribute with values including `#ffffff`, `#FFFFFF` and `#fffFFF`. This happens even if `bgcolor` has no effect for a given element (e.g., `div`[p251]).

The selector `[type=a s]` will match any HTML element with a `type` attribute whose value is `a`, but not whose value is `A`, due to the `s` flag.

All other attribute values and everything else must be treated as entirely identical to each other for the purposes of selector matching. This includes:

- IDs and classes in no-quirks mode and limited-quirks mode
- the names of elements not in the HTML namespace
- the names of HTML elements[p45] in XML documents
- the names of attributes of elements not in the HTML namespace
- the names of attributes of HTML elements[p45] in XML documents
- the names of attributes that themselves have namespaces

Note

Selectors *defines that ID and class selectors (such as* `#foo` *and* `.bar`*), when matched against elements in documents that are in quirks mode, will be matched in an ASCII case-insensitive manner. However, this does not apply for attribute selectors with* `"id"` *or* `"class"` *as the name part. The selector* `[class="foobar"]` *will treat its value as case-sensitive even in quirks mode.*

4.16.3 Pseudo-classes §[p76] 4

There are a number of dynamic selectors that can be used with HTML. This section defines when these selectors match HTML elements. [SELECTORS][p1417] [CSSUI][p1412]

`:defined`

The `:defined`[p764] pseudo-class must match any element that is defined.

:link
:visited

All a[p252] elements that have an href[p297] attribute, and all area[p463] elements that have an href[p297] attribute, must match one of :link[p765] and :visited[p765].

Other specifications might apply more specific rules regarding how these elements are to match these pseudo-classes, to mitigate some privacy concerns that apply with straightforward implementations of this requirement.

:active

The :active[p765] pseudo-class is defined to match an element “while an element is ***being activated*** by the user”.

To determine whether a particular element is *being activated*[p765] for the purposes of defining the :active[p765] pseudo-class only, an HTML user agent must use the first relevant entry in the following list.

If the element is a button[p556] element

If the element is an input[p512] element whose type[p514] attribute is in the Submit Button[p537], Image Button[p538], Reset Button[p540], or Button[p540] state

If the element is an a[p252] element that has an href[p297] attribute

If the element is an area[p463] element that has an href[p297] attribute

If the element is focusable[p817]

The element is *being activated*[p765] if it is in a formal activation state[p765].

> **Example**
>
> For example, if the user is using a keyboard to push a button[p556] element by pressing the space bar, the element would match this pseudo-class in between the time that the element received the keydown event and the time the element received the keyup event.

If the element is being actively pointed at[p765]

The element is *being activated*[p765].

An element is said to be **in a formal activation state** between the time the user begins to indicate an intent to trigger the element's activation behavior and either the time the user stops indicating an intent to trigger the element's activation behavior, or the time the element's activation behavior has finished running, which ever comes first.

An element is said to be **being actively pointed at** while the user indicates the element using a pointing device while that pointing device is in the "down" state (e.g. for a mouse, between the time the mouse button is pressed and the time it is depressed; for a finger in a multitouch environment, while the finger is touching the display surface).

> **Note**
>
> *Per the definition in* Selectors, :active[p765] *also matches flat tree ancestors of elements that are* being activated[p765]. *[SELECTORS][p1417]*

Additionally, any element that is the labeled control[p510] of a label[p509] element that is currently matching :active[p765], also matches :active[p765]. (But, it does not count as being *being activated*[p765].)

:hover

The :hover[p765] pseudo-class is defined to match an element “while the user ***designates*** an element with a pointing device”. For the purposes of defining the :hover[p765] pseudo-class only, an HTML user agent must consider an element as being one that the user *designates*[p765] if it is an element that the user indicates using a pointing device.

> **Note**
>
> *Per the definition in* Selectors, :hover[p765] *also matches flat tree ancestors of elements that are* designated[p765]. *[SELECTORS][p1417]*

Additionally, any element that is the labeled control[p510] of a label[p509] element that is currently matching :hover[p765], also matches :hover[p765]. (But, it does not count as being *designated*[p765].)

> **Example**

Consider in particular a fragment such as:

```
<p> <label for=c> <input id=a> </label> <span id=b> <input id=c> </span> </p>
```

If the user designates the element with ID "a" with their pointing device, then the p[p223] element (and all its ancestors not shown in the snippet above), the label[p509] element, the element with ID "a", and the element with ID "c" will match the :hover[p765] pseudo-class. The element with ID "a" matches it by being *designated*[p765]; the label[p509] and p[p223] elements match it because of the condition in *Selectors* about flat tree ancestors; and the element with ID "c" matches it through the additional condition above on labeled controls[p510] (i.e., its label[p509] element matches :hover[p765]). However, the element with ID "b" does *not* match :hover[p765]: its flat tree descendant is not designated, even though that flat tree descendant matches :hover[p765].

:focus

For the purposes of the CSS :focus[p766] pseudo-class, an **element has the focus** when:

- it is not itself a navigable container[p955]; and
- at least one of the following is true:
  - it is one of the elements listed in the current focus chain of the top-level traversable[p817], or
  - its shadow root *shadowRoot* is not null and *shadowRoot* is the root of at least one element that has the focus[p766].

:target

For the purposes of the CSS :target[p766] pseudo-class, the Document[p127]'s *target elements* are a list containing the Document[p127]'s target element[p1012], if it is not null, or containing no elements, if it is. [SELECTORS][p1417]

:popover-open

The :popover-open[p766] pseudo-class is defined to match any HTML element[p45] whose popover[p857] attribute is not in the no popover state[p859] and whose popover visibility state[p859] is showing[p859].

:enabled

The :enabled[p766] pseudo-class must match any button[p556], input[p512], select[p559], textarea[p570], optgroup[p566], option[p567], fieldset[p584] element, or form-associated custom element[p743] that is not actually disabled[p763].

:disabled

The :disabled[p766] pseudo-class must match any element that is actually disabled[p763].

:checked

The :checked[p766] pseudo-class must match any element falling into one of the following categories:

- input[p512] elements whose type[p514] attribute is in the Checkbox[p533] state and whose checkedness[p587] state is true
- input[p512] elements whose type[p514] attribute is in the Radio Button[p534] state and whose checkedness[p587] state is true
- option[p567] elements whose selectedness[p568] is true

:indeterminate

The :indeterminate[p766] pseudo-class must match any element falling into one of the following categories:

- input[p512] elements whose type[p514] attribute is in the Checkbox[p533] state and whose indeterminate[p518] IDL attribute is set to true
- input[p512] elements whose type[p514] attribute is in the Radio Button[p534] state and whose radio button group[p534] contains no input[p512] elements whose checkedness[p587] state is true.
- progress[p577] elements with no value[p577] content attribute

:default

The :default[p766] pseudo-class must match any element falling into one of the following categories:

- Submit buttons[p505] that are default buttons[p618] of their form owner[p588].
- input[p512] elements to which the checked[p516] attribute applies and that have a checked[p516] attribute

- option[p567] elements that have a selected[p568] attribute

:placeholder-shown

The :placeholder-shown[p767] pseudo-class must match any element falling into one of the following categories:

- input[p512] elements that have a placeholder[p550] attribute whose value is currently being presented to the user.
- textarea[p570] elements that have a placeholder[p573] attribute whose value is currently being presented to the user.

:valid

The :valid[p767] pseudo-class must match any element falling into one of the following categories:

- elements that are candidates for constraint validation[p612] and that satisfy their constraints[p613]
- form[p505] elements that are not the form owner[p588] of any elements that themselves are candidates for constraint validation[p612] but do not satisfy their constraints[p613]
- fieldset[p584] elements that have no descendant elements that themselves are candidates for constraint validation[p612] but do not satisfy their constraints[p613]

:invalid

The :invalid[p767] pseudo-class must match any element falling into one of the following categories:

- elements that are candidates for constraint validation[p612] but that do not satisfy their constraints[p613]
- form[p505] elements that are the form owner[p588] of one or more elements that themselves are candidates for constraint validation[p612] but do not satisfy their constraints[p613]
- fieldset[p584] elements that have of one or more descendant elements that themselves are candidates for constraint validation[p612] but do not satisfy their constraints[p613]

:in-range

The :in-range[p767] pseudo-class must match all elements that are candidates for constraint validation[p612], have range limitations[p546], and that are neither suffering from an underflow[p613] nor suffering from an overflow[p613].

:out-of-range

The :out-of-range[p767] pseudo-class must match all elements that are candidates for constraint validation[p612], have range limitations[p546], and that are either suffering from an underflow[p613] or suffering from an overflow[p613].

:required

The :required[p767] pseudo-class must match any element falling into one of the following categories:

- input[p512] elements that are *required*[p543]
- select[p559] elements that have a required[p560] attribute
- textarea[p570] elements that have a required[p573] attribute

:optional

The :optional[p767] pseudo-class must match any element falling into one of the following categories:

- input[p512] elements to which the required[p543] attribute applies that are not *required*[p543]
- select[p559] elements that do not have a required[p560] attribute
- textarea[p570] elements that do not have a required[p573] attribute

:autofill

:-webkit-autofill

The :autofill[p767] and :-webkit-autofill[p767] pseudo-classes must match input[p512] elements which have been autofilled by user agent. These pseudo-classes must stop matching if the user edits the autofilled field.

Note

One way such autofilling might happen is via the autocomplete[p594] attribute, but user agents could autofill even without that attribute being involved.

:read-only

:read-write

The `:read-write`[p768] pseudo-class must match any element falling into one of the following categories, which for the purposes of Selectors are thus considered *user-alterable*: [SELECTORS][p1417]

- `input`[p512] elements to which the `readonly`[p542] attribute applies, and that are *mutable*[p588] (i.e. that do not have the `readonly`[p542] attribute specified and that are not disabled[p592])
- `textarea`[p570] elements that do not have a `readonly`[p571] attribute, and that are not disabled[p592]
- elements that are editing hosts[p835] or editable and are neither `input`[p512] elements nor `textarea`[p570] elements

The `:read-only`[p768] pseudo-class must match all other HTML elements[p45].

:modal

The `:modal`[p768] pseudo-class must match any element falling into one of the following categories:

- `dialog`[p633] elements whose is modal[p638] flag is true
- elements whose fullscreen flag is true

:dir(ltr)

The `:dir(ltr)`[p768] pseudo-class must match all elements whose directionality[p157] is 'ltr[p157]'.

:dir(rtl)

The `:dir(rtl)`[p768] pseudo-class must match all elements whose directionality[p157] is 'rtl[p157]'.

Note

This specification does not define when an element matches the `:lang()` *dynamic pseudo-class, as it is defined in sufficient detail in a language-agnostic fashion in* Selectors. *[SELECTORS][p1417]*

5 Microdata §p769

5.1 Introduction §p769

5.1.1 Overview §p769

This section is non-normative.

Sometimes, it is desirable to annotate content with specific machine-readable labels, e.g. to allow generic scripts to provide services that are customized to the page, or to enable content from a variety of cooperating authors to be processed by a single script in a consistent manner.

For this purpose, authors can use the microdata features described in this section. Microdata allows nested groups of name-value pairs to be added to documents, in parallel with the existing content.

5.1.2 The basic syntax §p769

This section is non-normative.

At a high level, microdata consists of a group of name-value pairs. The groups are called items[p774], and each name-value pair is a property. Items and properties are represented by regular elements.

To create an item, the `itemscope`[p774] attribute is used.

To add a property to an item, the `itemprop`[p776] attribute is used on one of the item's[p774] descendants.

Example

Here there are two items, each of which has the property "name":

```
<div itemscope>
 <p>My name is <span itemprop="name">Elizabeth</span>.</p>
</div>

<div itemscope>
 <p>My name is <span itemprop="name">Daniel</span>.</p>
</div>
```

Markup without the microdata-related attributes does not have any effect on the microdata model.

Example

These two examples are exactly equivalent, at a microdata level, as the previous two examples respectively:

```
<div itemscope>
 <p>My <em>name</em> is <span itemprop="name">E<strong>liz</strong>abeth</span>.</p>
</div>

<section>
 <div itemscope>
  <aside>
   <p>My name is <span itemprop="name"><a href="/?user=daniel">Daniel</a></span>.</p>
  </aside>
 </div>
</section>
```

Properties generally have values that are strings.

Example

Here the item has three properties:

```
<div itemscope>
 <p>My name is <span itemprop="name">Neil</span>.</p>
 <p>My band is called <span itemprop="band">Four Parts Water</span>.</p>
 <p>I am <span itemprop="nationality">British</span>.</p>
</div>
```

When a string value is a URL, it is expressed using the a[p252] element and its href[p297] attribute, the img[p338] element and its src[p340] attribute, or other elements that link to or embed external resources.

Example

In this example, the item has one property, "image", whose value is a URL:

```
<div itemscope>
 <img itemprop="image" src="google-logo.png" alt="Google">
</div>
```

When a string value is in some machine-readable format unsuitable for human consumption, it is expressed using the value[p273] attribute of the data[p273] element, with the human-readable version given in the element's contents.

Example

Here, there is an item with a property whose value is a product ID. The ID is not human-friendly, so the product's name is used the human-visible text instead of the ID.

```
<h1 itemscope>
 <data itemprop="product-id" value="9678AOU879">The Instigator 2000</data>
</h1>
```

For numeric data, the meter[p579] element and its value[p580] attribute can be used instead.

Example

Here a rating is given using a meter[p579] element.

```
<div itemscope itemtype="http://schema.org/Product">
 <span itemprop="name">Panasonic White 60L Refrigerator</span>
 <img src="panasonic-fridge-60l-white.jpg" alt="">
  <div itemprop="aggregateRating"
       itemscope itemtype="http://schema.org/AggregateRating">
   <meter itemprop="ratingValue" min=0 value=3.5 max=5>Rated 3.5/5</meter>
   (based on <span itemprop="reviewCount">11</span> customer reviews)
  </div>
</div>
```

Similarly, for date- and time-related data, the time[p274] element and its datetime[p274] attribute can be used instead.

Example

In this example, the item has one property, "birthday", whose value is a date:

```
<div itemscope>
 I was born on <time itemprop="birthday" datetime="2009-05-10">May 10th 2009</time>.
</div>
```

Properties can also themselves be groups of name-value pairs, by putting the itemscope[p774] attribute on the element that declares the property.

Items that are not part of others are called top-level microdata items[p779].

Example

In this example, the outer item represents a person, and the inner one represents a band:

```
<div itemscope>
 <p>Name: <span itemprop="name">Amanda</span></p>
 <p>Band: <span itemprop="band" itemscope> <span itemprop="name">Jazz Band</span> (<span
itemprop="size">12</span> players)</span></p>
</div>
```

The outer item here has two properties, "name" and "band". The "name" is "Amanda", and the "band" is an item in its own right, with two properties, "name" and "size". The "name" of the band is "Jazz Band", and the "size" is "12".

The outer item in this example is a top-level microdata item.

Properties that are not descendants of the element with the `itemscope`[p774] attribute can be associated with the item[p774] using the `itemref`[p775] attribute. This attribute takes a list of IDs of elements to crawl in addition to crawling the children of the element with the `itemscope`[p774] attribute.

Example

This example is the same as the previous one, but all the properties are separated from their items[p774]:

```
<div itemscope id="amanda" itemref="a b"></div>
<p id="a">Name: <span itemprop="name">Amanda</span></p>
<div id="b" itemprop="band" itemscope itemref="c"></div>
<div id="c">
 <p>Band: <span itemprop="name">Jazz Band</span></p>
 <p>Size: <span itemprop="size">12</span> players</p>
</div>
```

This gives the same result as the previous example. The first item has two properties, "name", set to "Amanda", and "band", set to another item. That second item has two further properties, "name", set to "Jazz Band", and "size", set to "12".

An item[p774] can have multiple properties with the same name and different values.

Example

This example describes an ice cream, with two flavors:

```
<div itemscope>
 <p>Flavors in my favorite ice cream:</p>
 <ul>
  <li itemprop="flavor">Lemon sorbet</li>
  <li itemprop="flavor">Apricot sorbet</li>
 </ul>
</div>
```

This thus results in an item with two properties, both "flavor", having the values "Lemon sorbet" and "Apricot sorbet".

An element introducing a property can also introduce multiple properties at once, to avoid duplication when some of the properties have the same value.

Example

Here we see an item with two properties, "favorite-color" and "favorite-fruit", both set to the value "orange":

```
<div itemscope>
 <span itemprop="favorite-color favorite-fruit">orange</span>
</div>
```

It's important to note that there is no relationship between the microdata and the content of the document where the microdata is marked up.

Example

There is no semantic difference, for instance, between the following two examples:

```
<figure>
 <img src="castle.jpeg">
 <figcaption><span itemscope><span itemprop="name">The Castle</span></span> (1986)</figcaption>
</figure>
```

```
<span itemscope><meta itemprop="name" content="The Castle"></span>
<figure>
 <img src="castle.jpeg">
 <figcaption>The Castle (1986)</figcaption>
</figure>
```

Both have a figure with a caption, and both, completely unrelated to the figure, have an item with a name-value pair with the name "name" and the value "The Castle". The only difference is that if the user drags the caption out of the document, in the former case, the item will be included in the drag-and-drop data. In neither case is the image in any way associated with the item.

5.1.3 Typed items §[p77 2]

This section is non-normative.

The examples in the previous section show how information could be marked up on a page that doesn't expect its microdata to be re-used. Microdata is most useful, though, when it is used in contexts where other authors and readers are able to cooperate to make new uses of the markup.

For this purpose, it is necessary to give each item[p774] a type, such as "https://example.com/person", or "https://example.org/cat", or "https://band.example.net/". Types are identified as URLs.

The type for an item[p774] is given as the value of an `itemtype`[p774] attribute on the same element as the `itemscope`[p774] attribute.

Example

Here, the item's type is "https://example.org/animals#cat":

```
<section itemscope itemtype="https://example.org/animals#cat">
 <h1 itemprop="name">Hedral</h1>
 <p itemprop="desc">Hedral is a male american domestic
 shorthair, with a fluffy black fur with white paws and belly.</p>
 <img itemprop="img" src="hedral.jpeg" alt="" title="Hedral, age 18 months">
</section>
```

In this example the "https://example.org/animals#cat" item has three properties, a "name" ("Hedral"), a "desc" ("Hedral is..."), and an "img" ("hedral.jpeg").

The type gives the context for the properties, thus selecting a vocabulary: a property named "class" given for an item with the type "https://census.example/person" might refer to the economic class of an individual, while a property named "class" given for an item with the type "https://example.com/school/teacher" might refer to the classroom a teacher has been assigned. Several types can share a vocabulary. For example, the types "`https://example.org/people/teacher`" and "`https://example.org/people/engineer`" could be defined to use the same vocabulary (though maybe some properties would not be especially useful in both cases, e.g. maybe the "`https://example.org/people/engineer`" type might not typically be used with the "`classroom`" property). Multiple types defined to use the same vocabulary can be given for a single item by listing the URLs as a space-separated list in the attribute' value. An item cannot be given two types if they do not use the same vocabulary, however.

5.1.4 Global identifiers for items §[p773]

This section is non-normative.

Sometimes, an item[p774] gives information about a topic that has a global identifier. For example, books can be identified by their ISBN number.

Vocabularies (as identified by the `itemtype`[p774] attribute) can be designed such that items[p774] get associated with their global identifier in an unambiguous way by expressing the global identifiers as URLs given in an `itemid`[p775] attribute.

The exact meaning of the URLs given in `itemid`[p775] attributes depends on the vocabulary used.

Example

Here, an item is talking about a particular book:

```
<dl itemscope
    itemtype="https://vocab.example.net/book"
    itemid="urn:isbn:0-330-34032-8">
 <dt>Title
 <dd itemprop="title">The Reality Dysfunction
 <dt>Author
 <dd itemprop="author">Peter F. Hamilton
 <dt>Publication date
 <dd><time itemprop="pubdate" datetime="1996-01-26">26 January 1996</time>
</dl>
```

The "`https://vocab.example.net/book`" vocabulary in this example would define that the `itemid`[p775] attribute takes a `urn:` URL pointing to the ISBN of the book.

5.1.5 Selecting names when defining vocabularies §[p773]

This section is non-normative.

Using microdata means using a vocabulary. For some purposes, an ad-hoc vocabulary is adequate. For others, a vocabulary will need to be designed. Where possible, authors are encouraged to re-use existing vocabularies, as this makes content re-use easier.

When designing new vocabularies, identifiers can be created either using URLs, or, for properties, as plain words (with no dots or colons). For URLs, conflicts with other vocabularies can be avoided by only using identifiers that correspond to pages that the author has control over.

Example

For instance, if Jon and Adam both write content at `example.com`, at `https://example.com/~jon/...` and `https://example.com/~adam/...` respectively, then they could select identifiers of the form "https://example.com/~jon/name" and "https://example.com/~adam/name" respectively.

Properties whose names are just plain words can only be used within the context of the types for which they are intended; properties named using URLs can be reused in items of any type. If an item has no type, and is not part of another item, then if its properties have names that are just plain words, they are not intended to be globally unique, and are instead only intended for limited use. Generally speaking, authors are encouraged to use either properties with globally unique names (URLs) or ensure that their items are typed.

Example

Here, an item is an "https://example.org/animals#cat", and most of the properties have names that are words defined in the context of that type. There are also a few additional properties whose names come from other vocabularies.

```
<section itemscope itemtype="https://example.org/animals#cat">
 <h1 itemprop="name https://example.com/fn">Hedral</h1>
 <p itemprop="desc">Hedral is a male American domestic
```

```
 shorthair, with a fluffy <span
 itemprop="https://example.com/color">black</span> fur with <span
 itemprop="https://example.com/color">white</span> paws and belly.</p>
 <img itemprop="img" src="hedral.jpeg" alt="" title="Hedral, age 18 months">
</section>
```

This example has one item with the type "https://example.org/animals#cat" and the following properties:

Property	Value
name	Hedral
https://example.com/fn	Hedral
desc	Hedral is a male American domestic shorthair, with a fluffy black fur with white paws and belly.
https://example.com/color	black
https://example.com/color	white

5.2 Encoding microdata §[p77 4]

5.2.1 The microdata model §[p77 4]

The microdata model consists of groups of name-value pairs known as items[p774].

Each group is known as an item[p774]. Each item[p774] can have item types[p774], a global identifier[p775] (if the vocabulary specified by the item types[p774] support global identifiers for items[p775]), and a list of name-value pairs. Each name in the name-value pair is known as a property[p779], and each property[p779] has one or more values[p778]. Each value[p778] is either a string or itself a group of name-value pairs (an item[p774]). The names are unordered relative to each other, but if a particular name has multiple values, they do have a relative order.

5.2.2 Items §[p77 4]

Every HTML element[p45] may have an **itemscope** attribute specified. The `itemscope`[p774] attribute is a boolean attribute[p72]. ✔ MDN

An element with the `itemscope`[p774] attribute specified creates a new **item**, a group of name-value pairs.

Elements with an `itemscope`[p774] attribute may have an **itemtype** attribute specified, to give the item types[p774] of the item[p774]. ✔ MDN

The `itemtype`[p774] attribute, if specified, must have a value that is an unordered set of unique space-separated tokens[p93], none of which are identical to another token and each of which is a valid URL string that is an absolute URL, and all of which are defined to use the same vocabulary. The attribute's value must have at least one token.

The **item types** of an item[p774] are the tokens obtained by splitting the element's `itemtype` attribute's value on ASCII whitespace. If the `itemtype`[p774] attribute is missing or parsing it in this way finds no tokens, the item[p774] is said to have no item types[p774].

The item types[p774] must all be types defined in applicable specifications[p70] and must all be defined to use the same vocabulary.

Except if otherwise specified by that specification, the URLs given as the item types[p774] should not be automatically dereferenced.

Note

A specification could define that its item type[p774] can be dereferenced to provide the user with help information, for example. In fact, vocabulary authors are encouraged to provide useful information at the given URL.

Item types[p774] are opaque identifiers, and user agents must not dereference unknown item types[p774], or otherwise deconstruct them, in order to determine how to process items[p774] that use them.

The `itemtype`[p774] attribute must not be specified on elements that do not have an `itemscope`[p774] attribute specified.

An item[p774] is said to be a **typed item** when either it has an item type[p774], or it is the value[p778] of a property[p779] of a typed item[p775]. The **relevant types** for a typed item[p775] is the item[p774]'s item types[p774], if it has any, or else is the relevant types[p775] of the item[p774] for which it is a property[p779]'s value[p778].

Elements with an `itemscope`[p774] attribute and an `itemtype`[p774] attribute that references a vocabulary that is defined to **support global identifiers for items** may also have an **`itemid`** attribute specified, to give a global identifier for the item[p774], so that it can be related to other items[p774] on pages elsewhere on the web.

The `itemid`[p775] attribute, if specified, must have a value that is a valid URL potentially surrounded by spaces[p94].

The **global identifier** of an item[p774] is the value of its element's `itemid`[p775] attribute, if it has one, parsed[p95] relative to the node document of the element on which the attribute is specified. If the `itemid`[p775] attribute is missing or if resolving it fails, it is said to have no global identifier[p775].

The `itemid`[p775] attribute must not be specified on elements that do not have both an `itemscope`[p774] attribute and an `itemtype`[p774] attribute specified, and must not be specified on elements with an `itemscope`[p774] attribute whose `itemtype`[p774] attribute specifies a vocabulary that does not support global identifiers for items[p775], as defined by that vocabulary's specification.

The exact meaning of a global identifier[p775] is determined by the vocabulary's specification. It is up to such specifications to define whether multiple items with the same global identifier (whether on the same page or on different pages) are allowed to exist, and what the processing rules for that vocabulary are with respect to handling the case of multiple items with the same ID.

Elements with an `itemscope`[p774] attribute may have an **`itemref`** attribute specified, to give a list of additional elements to crawl to find the name-value pairs of the item[p774].

The `itemref`[p775] attribute, if specified, must have a value that is an unordered set of unique space-separated tokens[p93] none of which are identical to another token and consisting of IDs of elements in the same tree.

The `itemref`[p775] attribute must not be specified on elements that do not have an `itemscope`[p774] attribute specified.

Note

The `itemref`[p775] attribute is not part of the microdata data model. It is merely a syntactic construct to aid authors in adding annotations to pages where the data to be annotated does not follow a convenient tree structure. For example, it allows authors to mark up data in a table so that each column defines a separate item[p774], while keeping the properties in the cells.

Example

This example shows a simple vocabulary used to describe the products of a model railway manufacturer. The vocabulary has just five property names:

product-code
: An integer that names the product in the manufacturer's catalog.

name
: A brief description of the product.

scale
: One of "HO", "1", or "Z" (potentially with leading or trailing whitespace), indicating the scale of the product.

digital
: If present, one of "Digital", "Delta", or "Systems" (potentially with leading or trailing whitespace) indicating that the product has a digital decoder of the given type.

track-type
: For track-specific products, one of "K", "M", "C" (potentially with leading or trailing whitespace) indicating the type of track for which the product is intended.

This vocabulary has four defined item types[p774]:

https://md.example.com/loco
: Rolling stock with an engine

https://md.example.com/passengers
Passenger rolling stock

https://md.example.com/track
Track pieces

https://md.example.com/lighting
Equipment with lighting

Each item[p774] that uses this vocabulary can be given one or more of these types, depending on what the product is.

Thus, a locomotive might be marked up as:

```
<dl itemscope itemtype="https://md.example.com/loco
                       https://md.example.com/lighting">
 <dt>Name:
 <dd itemprop="name">Tank Locomotive (DB 80)
 <dt>Product code:
 <dd itemprop="product-code">33041
 <dt>Scale:
 <dd itemprop="scale">HO
 <dt>Digital:
 <dd itemprop="digital">Delta
</dl>
```

A turnout lantern retrofit kit might be marked up as:

```
<dl itemscope itemtype="https://md.example.com/track
                       https://md.example.com/lighting">
 <dt>Name:
 <dd itemprop="name">Turnout Lantern Kit
 <dt>Product code:
 <dd itemprop="product-code">74470
 <dt>Purpose:
 <dd>For retrofitting 2 <span itemprop="track-type">C</span> Track
 turnouts. <meta itemprop="scale" content="HO">
</dl>
```

A passenger car with no lighting might be marked up as:

```
<dl itemscope itemtype="https://md.example.com/passengers">
 <dt>Name:
 <dd itemprop="name">Express Train Passenger Car (DB Am 203)
 <dt>Product code:
 <dd itemprop="product-code">8710
 <dt>Scale:
 <dd itemprop="scale">Z
</dl>
```

Great care is necessary when creating new vocabularies. Often, a hierarchical approach to types can be taken that results in a vocabulary where each item only ever has a single type, which is generally much simpler to manage.

5.2.3 Names: the `itemprop` attribute §[p776]

Every HTML element[p45] may have an `itemprop`[p776] attribute specified, if doing so adds one or more properties[p779] to one or more items[p774] (as defined below).

The `itemprop`[p776] attribute, if specified, must have a value that is an unordered set of unique space-separated tokens[p93] none of which

are identical to another token, representing the names of the name-value pairs that it adds. The attribute's value must have at least one token.

Each token must be either:

- If the item is a typed item[p775]: a **defined property name** allowed in this situation according to the specification that defines the relevant types[p775] for the item, or
- A valid URL string that is an absolute URL defined as an item property name allowed in this situation by a vocabulary specification, or
- A valid URL string that is an absolute URL, used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification), or
- If the item is not a typed item[p775]: a string that contains no U+002E FULL STOP characters (.) and no U+003A COLON characters (:), used as a proprietary item property name (i.e. one used by the author for private purposes, not defined in a public specification).

Specifications that introduce defined property names[p777] must ensure all such property names contain no U+002E FULL STOP characters (.), no U+003A COLON characters (:), and no ASCII whitespace.

Note

The rules above disallow U+003A COLON characters (:) in non-URL values because otherwise they could not be distinguished from URLs. Values with U+002E FULL STOP characters (.) are reserved for future extensions. ASCII whitespace are disallowed because otherwise the values would be parsed as multiple tokens.

When an element with an `itemprop`[p776] attribute adds a property[p779] to multiple items[p774], the requirement above regarding the tokens applies for each item[p774] individually.

The **property names** of an element are the tokens that the element's `itemprop`[p776] attribute is found to contain when its value is split on ASCII whitespace, with the order preserved but with duplicates removed (leaving only the first occurrence of each name).

Within an item[p774], the properties are unordered with respect to each other, except for properties with the same name, which are ordered in the order they are given by the algorithm that defines the properties of an item[p779].

Example

In the following example, the "a" property has the values "1" and "2", *in that order*, but whether the "a" property comes before the "b" property or not is not important:

```
<div itemscope>
 <p itemprop="a">1</p>
 <p itemprop="a">2</p>
 <p itemprop="b">test</p>
</div>
```

Thus, the following is equivalent:

```
<div itemscope>
 <p itemprop="b">test</p>
 <p itemprop="a">1</p>
 <p itemprop="a">2</p>
</div>
```

As is the following:

```
<div itemscope>
 <p itemprop="a">1</p>
 <p itemprop="b">test</p>
 <p itemprop="a">2</p>
</div>
```

And the following:

```
<div id="x">
 <p itemprop="a">1</p>
</div>
<div itemscope itemref="x">
 <p itemprop="b">test</p>
 <p itemprop="a">2</p>
</div>
```

5.2.4 Values §[p778]

The **property value** of a name-value pair added by an element with an `itemprop`[p776] attribute is as given for the first matching case in the following list:

↪ **If the element also has an `itemscope`[p774] attribute**

The value is the item[p774] created by the element.

↪ **If the element is a `meta`[p184] element**

The value is the value of the element's `content`[p185] attribute, if any, or the empty string if there is no such attribute.

↪ **If the element is an `audio`[p402], `embed`[p391], `iframe`[p383], `img`[p338], `source`[p335], `track`[p403], or `video`[p398] element**

The value is the resulting URL string[p95] that results from parsing[p95] the value of the element's `src` attribute relative to the node document of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing[p95] it results in an error.

↪ **If the element is an `a`[p252], `area`[p463], or `link`[p172] element**

The value is the resulting URL string[p95] that results from parsing[p95] the value of the element's `href` attribute relative to the node document of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing[p95] it results in an error.

↪ **If the element is an `object`[p394] element**

The value is the resulting URL string[p95] that results from parsing[p95] the value of the element's `data` attribute relative to the node document of the element at the time the attribute is set, or the empty string if there is no such attribute or if parsing[p95] it results in an error.

↪ **If the element is a `data`[p273] element**

The value is the value of the element's `value`[p273] attribute, if it has one, or the empty string otherwise.

↪ **If the element is a `meter`[p579] element**

The value is the value of the element's `value`[p580] attribute, if it has one, or the empty string otherwise.

↪ **If the element is a `time`[p274] element**

The value is the element's datetime value[p274].

↪ **Otherwise**

The value is the element's descendant text content.

The **URL property elements** are the `a`[p252], `area`[p463], `audio`[p402], `embed`[p391], `iframe`[p383], `img`[p338], `link`[p172], `object`[p394], `source`[p335], `track`[p403], and `video`[p398] elements.

If a property's value[p778], as defined by the property's definition, is an absolute URL, the property must be specified using a URL property element[p778].

Note

These requirements do not apply just because a property value happens to match the syntax for a URL. They only apply if the property is explicitly defined as taking such a value.

Example

For example, a book about the first moon landing could be called "mission:moon". A "title" property from a vocabulary that defines a title as being a string would not expect the title to be given in an a[p252] element, even though it looks like a URL. On the other hand, if there was a (rather narrowly scoped!) vocabulary for "books whose titles look like URLs" which had a "title" property defined to take a URL, then the property *would* expect the title to be given in an a[p252] element (or one of the other URL property elements[p778]), because of the requirement above.

5.2.5 Associating names with items §[p779]

To find **the properties of an item** defined by the element *root*, the user agent must run the following steps. These steps are also used to flag microdata errors[p779].

1. Let *results*, *memory*, and *pending* be empty lists of elements.
2. Add the element *root* to *memory*.
3. Add the child elements of *root*, if any, to *pending*.
4. If *root* has an `itemref`[p775] attribute, split the value of that `itemref` attribute on ASCII whitespace. For each resulting token *ID*, if there is an element in the tree of *root* with the ID *ID*, then add the first such element to *pending*.
5. While *pending* is not empty:
    1. Remove an element from *pending* and let *current* be that element.
    2. If *current* is already in *memory*, there is a microdata error[p779]; continue.
    3. Add *current* to *memory*.
    4. If *current* does not have an `itemscope`[p774] attribute, then: add all the child elements of *current* to *pending*.
    5. If *current* has an `itemprop`[p776] attribute specified and has one or more property names[p777], then add *current* to *results*.
6. Sort *results* in tree order.
7. Return *results*.

A document must not contain any items[p774] for which the algorithm to find the properties of an item[p779] finds any **microdata errors**.

An item[p774] is a **top-level microdata item** if its element does not have an `itemprop`[p776] attribute.

All `itemref`[p775] attributes in a `Document`[p127] must be such that there are no cycles in the graph formed from representing each item[p774] in the `Document`[p127] as a node in the graph and each property[p779] of an item whose value[p778] is another item as an edge in the graph connecting those two items.

A document must not contain any elements that have an `itemprop`[p776] attribute that would not be found to be a property of any of the items[p774] in that document were their properties[p779] all to be determined.

Example

In this example, a single license statement is applied to two works, using `itemref`[p775] from the items representing the works:

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <title>Photo gallery</title>
 </head>
 <body>
  <h1>My photos</h1>
  <figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
   <img itemprop="work" src="images/house.jpeg" alt="A white house, boarded up, sits in a forest.">
   <figcaption itemprop="title">The house I found.</figcaption>
```

```
  </figure>
  <figure itemscope itemtype="http://n.whatwg.org/work" itemref="licenses">
   <img itemprop="work" src="images/mailbox.jpeg" alt="Outside the house is a mailbox. It has a
leaflet inside.">
   <figcaption itemprop="title">The mailbox.</figcaption>
  </figure>
  <footer>
   <p id="licenses">All images licensed under the <a itemprop="license"
   href="http://www.opensource.org/licenses/mit-license.php">MIT
   license</a>.</p>
  </footer>
 </body>
</html>
```

The above results in two items with the type "`http://n.whatwg.org/work`", one with:

work
`images/house.jpeg`

title
The house I found.

license
`http://www.opensource.org/licenses/mit-license.php`

...and one with:

work
`images/mailbox.jpeg`

title
The mailbox.

license
`http://www.opensource.org/licenses/mit-license.php`

5.2.6 Microdata and other namespaces §[p78] [0]

Currently, the `itemscope`[p774], `itemprop`[p776], and other microdata attributes are only defined for HTML elements[p45]. This means that attributes with the literal names "`itemscope`", "`itemprop`", etc, do not cause microdata processing to occur on elements in other namespaces, such as SVG.

Example

Thus, in the following example there is only one item, not two.

```
<p itemscope></p> <!-- this is an item (with no properties and no type) -->
<svg itemscope></svg> <!-- this is not, it's just an SVG svg element with an invalid unknown
attribute -->
```

5.3 Sample microdata vocabularies §[p78] [0]

The vocabularies in this section are primarily intended to demonstrate how a vocabulary is specified, though they are also usable in their own right.

5.3.1 vCard §[p781]

An item with the item type[p774] **http://microformats.org/profile/hcard** represents a person's or organization's contact information.

This vocabulary does not support global identifiers for items[p775].

The following are the type's defined property names[p777]. They are based on the vocabulary defined in *vCard Format Specification* (*vCard*) and its extensions, where more information on how to interpret the values can be found. [RFC6350][p1416]

kind

Describes what kind of contact the item represents.

The value[p778] must be text that is identical to one of the kind strings[p788].

A single property with the name kind[p781] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

fn

Gives the formatted text corresponding to the name of the person or organization.

The value[p778] must be text.

Exactly one property with the name fn[p781] must be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

n

Gives the structured name of the person or organization.

The value[p778] must be an item[p774] with zero or more of each of the family-name[p781], given-name[p781], additional-name[p781], honorific-prefix[p781], and honorific-suffix[p782] properties.

Exactly one property with the name n[p781] must be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

family-name (inside n[p781])

Gives the family name of the person, or the full name of the organization.

The value[p778] must be text.

Any number of properties with the name family-name[p781] may be present within the item[p774] that forms the value[p778] of the n[p781] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

given-name (inside n[p781])

Gives the given-name of the person.

The value[p778] must be text.

Any number of properties with the name given-name[p781] may be present within the item[p774] that forms the value[p778] of the n[p781] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

additional-name (inside n[p781])

Gives the any additional names of the person.

The value[p778] must be text.

Any number of properties with the name additional-name[p781] may be present within the item[p774] that forms the value[p778] of the n[p781] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

honorific-prefix (inside n[p781])

Gives the honorific prefix of the person.

The value[p778] must be text.

Any number of properties with the name honorific-prefix[p781] may be present within the item[p774] that forms the value[p778] of the

n[p781] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

honorific-suffix (inside n[p781])

Gives the honorific suffix of the person.

The value[p778] must be text.

Any number of properties with the name honorific-suffix[p782] may be present within the item[p774] that forms the value[p778] of the n[p781] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

nickname

Gives the nickname of the person or organization.

Note

The nickname is the descriptive name given instead of or in addition to the one belonging to a person, place, or thing. It can also be used to specify a familiar form of a proper name specified by the fn[p781] or n[p781] properties.

The value[p778] must be text.

Any number of properties with the name nickname[p782] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

photo

Gives a photograph of the person or organization.

The value[p778] must be an absolute URL.

Any number of properties with the name photo[p782] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

bday

Gives the birth date of the person or organization.

The value[p778] must be a valid date string[p80].

A single property with the name bday[p782] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

anniversary

Gives the birth date of the person or organization.

The value[p778] must be a valid date string[p80].

A single property with the name anniversary[p782] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

sex

Gives the biological sex of the person.

The value[p778] must be one of F, meaning "female", M, meaning "male", N, meaning "none or not applicable", O, meaning "other", or U, meaning "unknown".

A single property with the name sex[p782] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

gender-identity

Gives the gender identity of the person.

The value[p778] must be text.

A single property with the name gender-identity[p782] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

adr

Gives the delivery address of the person or organization.

The value[p778] must be an item[p774] with zero or more type[p783], post-office-box[p783], extended-address[p783], and street-address[p783] properties, and optionally a locality[p783] property, optionally a region[p783] property, optionally a postal-code[p784] property, and optionally a country-name[p784] property.

If no type[p783] properties are present within an item[p774] that forms the value[p778] of an adr[p783] property of an item[p774] with the type http://microformats.org/profile/hcard[p781], then the address type string[p788] work[p788] is implied.

Any number of properties with the name adr[p783] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

type (inside adr[p783])

Gives the type of delivery address.

The value[p778] must be text that is identical to one of the address type strings[p788].

Any number of properties with the name type[p783] may be present within the item[p774] that forms the value[p778] of an adr[p783] property of an item[p774] with the type http://microformats.org/profile/hcard[p781], but within each such adr[p783] property item[p774] there must only be one type[p783] property per distinct value.

post-office-box (inside adr[p783])

Gives the post office box component of the delivery address of the person or organization.

The value[p778] must be text.

Any number of properties with the name post-office-box[p783] may be present within the item[p774] that forms the value[p778] of an adr[p783] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

Note

vCard *urges authors not to use this field.*

extended-address (inside adr[p783])

Gives an additional component of the delivery address of the person or organization.

The value[p778] must be text.

Any number of properties with the name extended-address[p783] may be present within the item[p774] that forms the value[p778] of an adr[p783] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

Note

vCard *urges authors not to use this field.*

street-address (inside adr[p783])

Gives the street address component of the delivery address of the person or organization.

The value[p778] must be text.

Any number of properties with the name street-address[p783] may be present within the item[p774] that forms the value[p778] of an adr[p783] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

locality (inside adr[p783])

Gives the locality component (e.g. city) of the delivery address of the person or organization.

The value[p778] must be text.

A single property with the name locality[p783] may be present within the item[p774] that forms the value[p778] of an adr[p783] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

region (inside adr[p783])

Gives the region component (e.g. state or province) of the delivery address of the person or organization.

The value[p778] must be text.

A single property with the name region[p783] may be present within the item[p774] that forms the value[p778] of an adr[p783] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

postal-code (inside adr[p783])

Gives the postal code component of the delivery address of the person or organization.

The value[p778] must be text.

A single property with the name postal-code[p784] may be present within the item[p774] that forms the value[p778] of an adr[p783] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

country-name (inside adr[p783])

Gives the country name component of the delivery address of the person or organization.

The value[p778] must be text.

A single property with the name country-name[p784] may be present within the item[p774] that forms the value[p778] of an adr[p783] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

tel

Gives the telephone number of the person or organization.

The value[p778] must be either text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121, or an item[p774] with zero or more type[p784] properties and exactly one value[p784] property. [E163][p1413] [X121][p1418]

If no type[p784] properties are present within an item[p774] that forms the value[p778] of a tel[p784] property of an item[p774] with the type http://microformats.org/profile/hcard[p781], or if the value[p778] of such a tel[p784] property is text, then the telephone type string[p788] voice[p788] is implied.

Any number of properties with the name tel[p784] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

type (inside tel[p784])

Gives the type of telephone number.

The value[p778] must be text that is identical to one of the telephone type strings[p788].

Any number of properties with the name type[p784] may be present within the item[p774] that forms the value[p778] of a tel[p784] property of an item[p774] with the type http://microformats.org/profile/hcard[p781], but within each such tel[p784] property item[p774] there must only be one type[p784] property per distinct value.

value (inside tel[p784])

Gives the actual telephone number of the person or organization.

The value[p778] must be text that can be interpreted as a telephone number as defined in the CCITT specifications E.163 and X.121. [E163][p1413] [X121][p1418]

Exactly one property with the name value[p784] must be present within the item[p774] that forms the value[p778] of a tel[p784] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

email

Gives the email address of the person or organization.

The value[p778] must be text.

Any number of properties with the name email[p784] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

impp

Gives a URL for instant messaging and presence protocol communications with the person or organization.

The value[p778] must be an absolute URL.

Any number of properties with the name impp[p784] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

lang

Gives a language understood by the person or organization.

The value[p778] must be a valid BCP 47 language tag. [BCP47][p1410].

Any number of properties with the name lang[p785] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

tz

Gives the time zone of the person or organization.

The value[p778] must be text and must match the following syntax:

1. Either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. A valid non-negative integer[p74] that is exactly two digits long and that represents a number in the range 00..23.
3. A U+003A COLON character (:).
4. A valid non-negative integer[p74] that is exactly two digits long and that represents a number in the range 00..59.

Any number of properties with the name tz[p785] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

geo

Gives the geographical position of the person or organization.

The value[p778] must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more ASCII digits.
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.
4. A U+003B SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more ASCII digits.
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.

The optional components marked with an asterisk (*) should be included, and should have six digits each.

Note

The value specifies latitude and longitude, in that order (i.e., "LAT LON" ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.

Any number of properties with the name geo[p785] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

title

Gives the job title, functional position or function of the person or organization.

The value[p778] must be text.

Any number of properties with the name title[p785] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

role

Gives the role, occupation, or business category of the person or organization.

The value[p778] must be text.

Any number of properties with the name role[p785] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

logo

Gives the logo of the person or organization.

The value[p778] must be an absolute URL.

Any number of properties with the name logo[p786] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

agent

Gives the contact information of another person who will act on behalf of the person or organization.

The value[p778] must be either an item[p774] with the type http://microformats.org/profile/hcard[p781], or an absolute URL, or text.

Any number of properties with the name agent[p786] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

org

Gives the name and units of the organization.

The value[p778] must be either text or an item[p774] with one organization-name[p786] property and zero or more organization-unit[p786] properties.

Any number of properties with the name org[p786] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

organization-name (inside org[p786])

Gives the name of the organization.

The value[p778] must be text.

Exactly one property with the name organization-name[p786] must be present within the item[p774] that forms the value[p778] of an org[p786] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

organization-unit (inside org[p786])

Gives the name of the organization unit.

The value[p778] must be text.

Any number of properties with the name organization-unit[p786] may be present within the item[p774] that forms the value[p778] of the org[p786] property of an item[p774] with the type http://microformats.org/profile/hcard[p781].

member

Gives a URL that represents a member of the group.

The value[p778] must be an absolute URL.

Any number of properties with the name member[p786] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781] if the item[p774] also has a property with the name kind[p781] whose value is "group[p788]".

related

Gives a relationship to another entity.

The value[p778] must be an item[p774] with one url[p786] property and one rel[p787] properties.

Any number of properties with the name related[p786] may be present within each item[p774] with the type http://microformats.org/profile/hcard[p781].

url (inside related[p786])

Gives the URL for the related entity.

The value[p778] must be an absolute URL.

Exactly one property with the name `url`[p786] must be present within the item[p774] that forms the value[p778] of a `related`[p786] property of an item[p774] with the type `http://microformats.org/profile/hcard`[p781].

`rel` (inside `related`[p786])

Gives the relationship between the entity and the related entity.

The value[p778] must be text that is identical to one of the relationship strings[p788].

Exactly one property with the name `rel`[p787] must be present within the item[p774] that forms the value[p778] of a `related`[p786] property of an item[p774] with the type `http://microformats.org/profile/hcard`[p781].

`categories`

Gives the name of a category or tag that the person or organization could be classified as.

The value[p778] must be text.

Any number of properties with the name `categories`[p787] may be present within each item[p774] with the type `http://microformats.org/profile/hcard`[p781].

`note`

Gives supplemental information or a comment about the person or organization.

The value[p778] must be text.

Any number of properties with the name `note`[p787] may be present within each item[p774] with the type `http://microformats.org/profile/hcard`[p781].

`rev`

Gives the revision date and time of the contact information.

The value[p778] must be text that is a valid global date and time string[p85].

Note

The value distinguishes the current revision of the information for other renditions of the information.

Any number of properties with the name `rev`[p787] may be present within each item[p774] with the type `http://microformats.org/profile/hcard`[p781].

`sound`

Gives a sound file relating to the person or organization.

The value[p778] must be an absolute URL.

Any number of properties with the name `sound`[p787] may be present within each item[p774] with the type `http://microformats.org/profile/hcard`[p781].

`uid`

Gives a globally unique identifier corresponding to the person or organization.

The value[p778] must be text.

A single property with the name `uid`[p787] may be present within each item[p774] with the type `http://microformats.org/profile/hcard`[p781].

`url`

Gives a URL relating to the person or organization.

The value[p778] must be an absolute URL.

Any number of properties with the name `url`[p787] may be present within each item[p774] with the type `http://microformats.org/profile/hcard`[p781].

The **kind strings** are:

`individual`
Indicates a single entity (e.g. a person).

`group`
Indicates multiple entities (e.g. a mailing list).

`org`
Indicates a single entity that is not a person (e.g. a company).

`location`
Indicates a geographical place (e.g. an office building).

The **address type strings** are:

`home`
Indicates a delivery address for a residence.

`work`
Indicates a delivery address for a place of work.

The **telephone type strings** are:

`home`
Indicates a residential number.

`work`
Indicates a telephone number for a place of work.

`text`
Indicates that the telephone number supports text messages (SMS).

`voice`
Indicates a voice telephone number.

`fax`
Indicates a facsimile telephone number.

`cell`
Indicates a cellular telephone number.

`video`
Indicates a video conferencing telephone number.

`pager`
Indicates a paging device telephone number.

`textphone`
Indicates a telecommunication device for people with hearing or speech difficulties.

The **relationship strings** are:

`emergency`
An emergency contact.

`agent`
Another entity that acts on behalf of this entity.

contact
acquaintance
friend
met
worker
colleague
resident
neighbor
child
parent
sibling
spouse
kin
muse
crush
date
sweetheart
me

Has the meaning defined in XFN. [XFN][p1418]

5.3.1.1 Conversion to vCard §[p789]

Given a list of nodes *nodes* in a `Document`[p127], a user agent must run the following algorithm to **extract any vCard data represented by those nodes** (only the first vCard is returned):

1. If none of the nodes in *nodes* are items[p774] with the item type[p774] `http://microformats.org/profile/hcard`[p781], then there is no vCard. Abort the algorithm, returning nothing.
2. Let *node* be the first node in *nodes* that is an item[p774] with the item type[p774] `http://microformats.org/profile/hcard`[p781].
3. Let *output* be an empty string.
4. Add a vCard line[p791] with the type "`BEGIN`" and the value "`VCARD`" to *output*.
5. Add a vCard line[p791] with the type "`PROFILE`" and the value "`VCARD`" to *output*.
6. Add a vCard line[p791] with the type "`VERSION`" and the value "`4.0`" to *output*.
7. Add a vCard line[p791] with the type "`SOURCE`" and the result of escaping the vCard text string[p792] that is the document's URL as the value to *output*.
8. If the `title` element[p132] is not null, add a vCard line[p791] with the type "`NAME`" and with the result of escaping the vCard text string[p792] obtained from the `title` element[p132]'s descendant text content as the value to *output*.
9. Let *sex* be the empty string.
10. Let *gender-identity* be the empty string.
11. For each element *element* that is a property of the item[p779] *node*: for each name *name* in *element*'s property names[p777], run the following substeps:
    1. Let *parameters* be an empty set of name-value pairs.
    2. Run the appropriate set of substeps from the following list. The steps will set a variable *value*, which is used in the next step.

       If the property's value[p778] is an item[p774] *subitem* and *name* is n[p781]

       1. Let *value* be the empty string.
       2. Append to *value* the result of collecting the first vCard subproperty[p792] named `family-name`[p781] in *subitem*.

3. Append a U+003B SEMICOLON character (;) to *value*.
4. Append to *value* the result of collecting the first vCard subproperty[p792] named `given-name`[p781] in *subitem*.
5. Append a U+003B SEMICOLON character (;) to *value*.
6. Append to *value* the result of collecting the first vCard subproperty[p792] named `additional-name`[p781] in *subitem*.
7. Append a U+003B SEMICOLON character (;) to *value*.
8. Append to *value* the result of collecting the first vCard subproperty[p792] named `honorific-prefix`[p781] in *subitem*.
9. Append a U+003B SEMICOLON character (;) to *value*.
10. Append to *value* the result of collecting the first vCard subproperty[p792] named `honorific-suffix`[p782] in *subitem*.

If the property's value[p778] is an item[p774] *subitem* and *name* is `adr`[p783]

1. Let *value* be the empty string.
2. Append to *value* the result of collecting vCard subproperties[p792] named `post-office-box`[p783] in *subitem*.
3. Append a U+003B SEMICOLON character (;) to *value*.
4. Append to *value* the result of collecting vCard subproperties[p792] named `extended-address`[p783] in *subitem*.
5. Append a U+003B SEMICOLON character (;) to *value*.
6. Append to *value* the result of collecting vCard subproperties[p792] named `street-address`[p783] in *subitem*.
7. Append a U+003B SEMICOLON character (;) to *value*.
8. Append to *value* the result of collecting the first vCard subproperty[p792] named `locality`[p783] in *subitem*.
9. Append a U+003B SEMICOLON character (;) to *value*.
10. Append to *value* the result of collecting the first vCard subproperty[p792] named `region`[p783] in *subitem*.
11. Append a U+003B SEMICOLON character (;) to *value*.
12. Append to *value* the result of collecting the first vCard subproperty[p792] named `postal-code`[p784] in *subitem*.
13. Append a U+003B SEMICOLON character (;) to *value*.
14. Append to *value* the result of collecting the first vCard subproperty[p792] named `country-name`[p784] in *subitem*.
15. If there is a property named `type`[p783] in *subitem*, and the first such property has a value[p778] that is not an item[p774] and whose value consists only of ASCII alphanumerics, then add a parameter named "TYPE" whose value is the value[p778] of that property to *parameters*.

If the property's value[p778] is an item[p774] *subitem* and *name* is `org`[p786]

1. Let *value* be the empty string.
2. Append to *value* the result of collecting the first vCard subproperty[p792] named `organization-name`[p786] in *subitem*.
3. For each property named `organization-unit`[p786] in *subitem*, run the following steps:
    1. If the value[p778] of the property is an item[p774], then skip this property.

2. Append a U+003B SEMICOLON character (;) to *value*.

3. Append the result of escaping the vCard text string[p792] given by the value[p778] of the property to *value*.

If the property's value[p778] is an item[p774] *subitem* with the item type[p774] `http://microformats.org/profile/hcard`[p781] and *name* is `related`[p786]

1. Let *value* be the empty string.

2. If there is a property named `url`[p786] in *subitem*, and its element is a URL property element[p778], then append the result of escaping the vCard text string[p792] given by the value[p778] of the first such property to *value*, and add a parameter with the name "`VALUE`" and the value "`URI`" to *parameters*.

3. If there is a property named `rel`[p787] in *subitem*, and the first such property has a value[p778] that is not an item[p774] and whose value consists only of ASCII alphanumerics, then add a parameter named "`RELATION`" whose value is the value[p778] of that property to *parameters*.

If the property's value[p778] is an item[p774] and *name* is none of the above

1. Let *value* be the result of collecting the first vCard subproperty[p792] named `value` in *subitem*.

2. If there is a property named `type` in *subitem*, and the first such property has a value[p778] that is not an item[p774] and whose value consists only of ASCII alphanumeric, then add a parameter named "`TYPE`" whose value is the value[p778] of that property to *parameters*.

If the property's value[p778] is not an item[p774] and its *name* is `sex`[p782]

If this is the first such property to be found, set *sex* to the property's value[p778].

If the property's value[p778] is not an item[p774] and its *name* is `gender-identity`[p782]

If this is the first such property to be found, set *gender-identity* to the property's value[p778].

Otherwise (the property's value[p778] is not an item[p774])

1. Let *value* be the property's value[p778].

2. If *element* is one of the URL property elements[p778], add a parameter with the name "`VALUE`" and the value "`URI`" to *parameters*.

3. Otherwise, if *name* is `bday`[p782] or `anniversary`[p782] and the *value* is a valid date string[p80], add a parameter with the name "`VALUE`" and the value "`DATE`" to *parameters*.

4. Otherwise, if *name* is `rev`[p787] and the *value* is a valid global date and time string[p85], add a parameter with the name "`VALUE`" and the value "`DATE-TIME`" to *parameters*.

5. Prefix every U+005C REVERSE SOLIDUS character (\) in *value* with another U+005C REVERSE SOLIDUS character (\).

6. Prefix every U+002C COMMA character (,) in *value* with a U+005C REVERSE SOLIDUS character (\).

7. Unless *name* is `geo`[p785], prefix every U+003B SEMICOLON character (;) in *value* with a U+005C REVERSE SOLIDUS character (\).

8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).

3. Add a vCard line[p791] with the type *name*, the parameters *parameters*, and the value *value* to *output*.

12. If either *sex* or *gender-identity* has a value that is not the empty string, add a vCard line[p791] with the type "`GENDER`" and the value consisting of the concatenation of *sex*, a U+003B SEMICOLON character (;), and *gender-identity* to *output*.

13. Add a vCard line[p791] with the type "`END`" and the value "`VCARD`" to *output*.

When the above algorithm says that the user agent is to **add a vCard line** consisting of a type *type*, optionally some parameters, and a value *value* to a string *output*, it must run the following steps:

1. Let *line* be an empty string.
2. Append *type*, converted to ASCII uppercase, to *line*.
3. If there are any parameters, then for each parameter, in the order that they were added, run these substeps:
    1. Append a U+003B SEMICOLON character (;) to *line*.
    2. Append the parameter's name to *line*.
    3. Append a U+003D EQUALS SIGN character (=) to *line*.
    4. Append the parameter's value to *line*.
4. Append a U+003A COLON character (:) to *line*.
5. Append *value* to *line*.
6. Let *maximum length* be 75.
7. While *line*'s code point length is greater than *maximum length*:
    1. Append the first *maximum length* code points of *line* to *output*.
    2. Remove the first *maximum length* code points from *line*.
    3. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
    4. Append a U+000A LINE FEED character (LF) to *output*.
    5. Append a U+0020 SPACE character to *output*.
    6. Let *maximum length* be 74.
8. Append (what remains of) *line* to *output*.
9. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
10. Append a U+000A LINE FEED character (LF) to *output*.

When the steps above require the user agent to obtain the result of **collecting vCard subproperties** named *subname* in *subitem*, the user agent must run the following steps:

1. Let *value* be the empty string.
2. For each property named *subname* in the item *subitem*, run the following substeps:
    1. If the value[p778] of the property is itself an item[p774], then skip this property.
    2. If this is not the first property named *subname* in *subitem* (ignoring any that were skipped by the previous step), then append a U+002C COMMA character (,) to *value*.
    3. Append the result of escaping the vCard text string[p792] given by the value[p778] of the property to *value*.
3. Return *value*.

When the steps above require the user agent to obtain the result of **collecting the first vCard subproperty** named *subname* in *subitem*, the user agent must run the following steps:

1. If there are no properties named *subname* in *subitem*, then return the empty string.
2. If the value[p778] of the first property named *subname* in *subitem* is an item[p774], then return the empty string.
3. Return the result of escaping the vCard text string[p792] given by the value[p778] of the first property named *subname* in *subitem*.

When the above algorithms say the user agent is to **escape the vCard text string** *value*, the user agent must use the following steps:

1. Prefix every U+005C REVERSE SOLIDUS character (\) in *value* with another U+005C REVERSE SOLIDUS character (\).
2. Prefix every U+002C COMMA character (,) in *value* with a U+005C REVERSE SOLIDUS character (\).

3. Prefix every U+003B SEMICOLON character (;) in *value* with a U+005C REVERSE SOLIDUS character (\).
4. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
5. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
6. Return the mutated *value*.

Note

This algorithm can generate invalid vCard output, if the input does not conform to the rules described for the http://microformats.org/profile/hcard[p781] *item type*[p774] *and defined property names*[p777].

5.3.1.2 Examples §[p793]

This section is non-normative.

Example

Here is a long example vCard for a fictional character called "Jack Bauer":

```
<section id="jack" itemscope itemtype="http://microformats.org/profile/hcard">
 <h1 itemprop="fn">
  <span itemprop="n" itemscope>
   <span itemprop="given-name">Jack</span>
   <span itemprop="family-name">Bauer</span>
  </span>
 </h1>
 <img itemprop="photo" alt="" src="jack-bauer.jpg">
 <p itemprop="org" itemscope>
  <span itemprop="organization-name">Counter-Terrorist Unit</span>
  (<span itemprop="organization-unit">Los Angeles Division</span>)
 </p>
 <p>
  <span itemprop="adr" itemscope>
   <span itemprop="street-address">10201 W. Pico Blvd.</span><br>
   <span itemprop="locality">Los Angeles</span>,
   <span itemprop="region">CA</span>
   <span itemprop="postal-code">90064</span><br>
   <span itemprop="country-name">United States</span><br>
  </span>
  <span itemprop="geo">34.052339;-118.410623</span>
 </p>
 <h2>Assorted Contact Methods</h2>
 <ul>
  <li itemprop="tel" itemscope>
   <span itemprop="value">+1 (310) 597 3781</span> <span itemprop="type">work</span>
   <meta itemprop="type" content="voice">
  </li>
  <li><a itemprop="url" href="https://en.wikipedia.org/wiki/Jack_Bauer">I'm on Wikipedia</a>
  so you can leave a message on my user talk page.</li>
  <li><a itemprop="url" href="http://www.jackbauerfacts.com/">Jack Bauer Facts</a></li>
  <li itemprop="email"><a
href="mailto:j.bauer@la.ctu.gov.invalid">j.bauer@la.ctu.gov.invalid</a></li>
  <li itemprop="tel" itemscope>
   <span itemprop="value">+1 (310) 555 3781</span> <span>
   <meta itemprop="type" content="cell">mobile phone</span>
  </li>
 </ul>
 <ins datetime="2008-07-20 21:00:00+01:00">
```

```
  <meta itemprop="rev" content="2008-07-20 21:00:00+01:00">
  <p itemprop="tel" itemscope><strong>Update!</strong>
  My new <span itemprop="type">home</span> phone number is
  <span itemprop="value">01632 960 123</span>.</p>
 </ins>
</section>
```

The odd line wrapping is needed because newlines are meaningful in microdata: newlines would be preserved in a conversion to, for example, the vCard format.

Example

This example shows a site's contact details (using the address[p217] element) containing an address with two street components:

```
<address itemscope itemtype="http://microformats.org/profile/hcard">
 <strong itemprop="fn"><span itemprop="n" itemscope><span itemprop="given-name">Alfred</span>
 <span itemprop="family-name">Person</span></span></strong> <br>
 <span itemprop="adr" itemscope>
  <span itemprop="street-address">1600 Amphitheatre Parkway</span> <br>
  <span itemprop="street-address">Building 43, Second Floor</span> <br>
  <span itemprop="locality">Mountain View</span>,
   <span itemprop="region">CA</span> <span itemprop="postal-code">94043</span>
 </span>
</address>
```

Example

The vCard vocabulary can be used to just mark up people's names:

```
<span itemscope itemtype="http://microformats.org/profile/hcard"
><span itemprop=fn><span itemprop="n" itemscope><span itemprop="given-name"
>George</span> <span itemprop="family-name">Washington</span></span
></span></span>
```

This creates a single item with a two name-value pairs, one with the name "fn" and the value "George Washington", and the other with the name "n" and a second item as its value, the second item having the two name-value pairs "given-name" and "family-name" with the values "George" and "Washington" respectively. This is defined to map to the following vCard:

```
BEGIN:VCARD
PROFILE:VCARD
VERSION:4.0
SOURCE:document's address
FN:George Washington
N:Washington;George;;;
END:VCARD
```

5.3.2 vEvent §[p79] 4

An item with the item type[p774] **`http://microformats.org/profile/hcalendar#vevent`** represents an event.

This vocabulary does not support global identifiers for items[p775].

The following are the type's defined property names[p777]. They are based on the vocabulary defined in *Internet Calendaring and Scheduling Core Object Specification* (*iCalendar*), where more information on how to interpret the values can be found. [RFC5545][p1416]

Note

Only the parts of the iCalendar vocabulary relating to events are used here; this vocabulary cannot express a complete iCalendar instance.

attach

Gives the address of an associated document for the event.

The value[p778] must be an absolute URL.

Any number of properties with the name `attach`[p795] may be present within each item[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794].

categories

Gives the name of a category or tag that the event could be classified as.

The value[p778] must be text.

Any number of properties with the name `categories`[p795] may be present within each item[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794].

class

Gives the access classification of the information regarding the event.

The value[p778] must be text with one of the following values:

- `public`
- `private`
- `confidential`

⚠Warning!

This is merely advisory and cannot be considered a confidentiality measure.

A single property with the name `class`[p795] may be present within each item[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794].

comment

Gives a comment regarding the event.

The value[p778] must be text.

Any number of properties with the name `comment`[p795] may be present within each item[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794].

description

Gives a detailed description of the event.

The value[p778] must be text.

A single property with the name `description`[p795] may be present within each item[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794].

geo

Gives the geographical position of the event.

The value[p778] must be text and must match the following syntax:

1. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
2. One or more ASCII digits.
3. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.
4. A U+003B SEMICOLON character (;).
5. Optionally, either a U+002B PLUS SIGN character (+) or a U+002D HYPHEN-MINUS character (-).
6. One or more ASCII digits.
7. Optionally*, a U+002E FULL STOP character (.) followed by one or more ASCII digits.

The optional components marked with an asterisk (*) should be included, and should have six digits each.

Note

The value specifies latitude and longitude, in that order (i.e., "LAT LON" ordering), in decimal degrees. The longitude represents the location east and west of the prime meridian as a positive or negative real number, respectively. The latitude represents the location north and south of the equator as a positive or negative real number, respectively.

A single property with the name geo[p795] may be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794].

location

Gives the location of the event.

The value[p778] must be text.

A single property with the name location[p796] may be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794].

resources

Gives a resource that will be needed for the event.

The value[p778] must be text.

Any number of properties with the name resources[p796] may be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794].

status

Gives the confirmation status of the event.

The value[p778] must be text with one of the following values:

- tentative
- confirmed
- canceled

A single property with the name status[p796] may be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794].

summary

Gives a short summary of the event.

The value[p778] must be text.

User agents should replace U+000A LINE FEED (LF) characters in the value[p778] by U+0020 SPACE characters when using the value.

A single property with the name summary[p796] may be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794].

dtend

Gives the date and time by which the event ends.

If the property with the name dtend[p796] is present within an item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794] that has a property with the name dtstart[p797] whose value is a valid date string[p80], then the value[p778] of the property with the name dtend[p796] must be text that is a valid date string[p80] also. Otherwise, the value[p778] of the property must be text that is a valid global date and time string[p85].

In either case, the value[p778] be later in time than the value of the dtstart[p797] property of the same item[p774].

Note

The time given by the dtend[p796] property is not inclusive. For day-long events, therefore, the dtend[p796] property's value[p778] will be the day after the end of the event.

A single property with the name dtend[p796] may be present within each item[p774] with the type http://microformats.org/profile/

hcalendar#vevent[p794], so long as that http://microformats.org/profile/hcalendar#vevent[p794] does not have a property with the name duration[p797].

dtstart

Gives the date and time at which the event starts.

The value[p778] must be text that is either a valid date string[p80] or a valid global date and time string[p85].

Exactly one property with the name dtstart[p797] must be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794].

duration

Gives the duration of the event.

The value[p778] must be text that is a valid vevent duration string[p798].

The duration represented is the sum of all the durations represented by integers in the value.

A single property with the name duration[p797] may be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794], so long as that http://microformats.org/profile/hcalendar#vevent[p794] does not have a property with the name dtend[p796].

transp

Gives whether the event is to be considered as consuming time on a calendar, for the purpose of free-busy time searches.

The value[p778] must be text with one of the following values:

- opaque
- transparent

A single property with the name transp[p797] may be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794].

contact

Gives the contact information for the event.

The value[p778] must be text.

Any number of properties with the name contact[p797] may be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794].

url

Gives a URL for the event.

The value[p778] must be an absolute URL.

A single property with the name url[p797] may be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794].

uid

Gives a globally unique identifier corresponding to the event.

The value[p778] must be text.

A single property with the name uid[p797] may be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794].

exdate

Gives a date and time at which the event does not occur despite the recurrence rules.

The value[p778] must be text that is either a valid date string[p80] or a valid global date and time string[p85].

Any number of properties with the name exdate[p797] may be present within each item[p774] with the type http://microformats.org/profile/hcalendar#vevent[p794].

rdate

Gives a date and time at which the event recurs.

The value[p778] must be text that is one of the following:

- A valid date string[p80].
- A valid global date and time string[p85].
- A valid global date and time string[p85] followed by a U+002F SOLIDUS character (/) followed by a second valid global date and time string[p85] representing a later time.
- A valid global date and time string[p85] followed by a U+002F SOLIDUS character (/) followed by a valid vevent duration string[p798].

Any number of properties with the name `rdate`[p798] may be present within each item[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794].

rrule

Gives a rule for finding dates and times at which the event occurs.

The value[p778] must be text that matches the RECUR value type defined in *iCalendar*. [RFC5545][p1416]

A single property with the name `rrule`[p798] may be present within each item[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794].

created

Gives the date and time at which the event information was first created in a calendaring system.

The value[p778] must be text that is a valid global date and time string[p85].

A single property with the name `created`[p798] may be present within each item[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794].

last-modified

Gives the date and time at which the event information was last modified in a calendaring system.

The value[p778] must be text that is a valid global date and time string[p85].

A single property with the name `last-modified`[p798] may be present within each item[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794].

sequence

Gives a revision number for the event information.

The value[p778] must be text that is a valid non-negative integer[p74].

A single property with the name `sequence`[p798] may be present within each item[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794].

A string is a **valid vevent duration string** if it matches the following pattern:

1. A U+0050 LATIN CAPITAL LETTER P character (P).
2. One of the following:
    - A valid non-negative integer[p74] followed by a U+0057 LATIN CAPITAL LETTER W character (W). The integer represents a duration of that number of weeks.
    - At least one, and possible both in this order, of the following:
        1. A valid non-negative integer[p74] followed by a U+0044 LATIN CAPITAL LETTER D character (D). The integer represents a duration of that number of days.
        2. A U+0054 LATIN CAPITAL LETTER T character (T) followed by any one of the following, or the first and second of the following in that order, or the second and third of the following in that order, or all three of the following in this order:
            1. A valid non-negative integer[p74] followed by a U+0048 LATIN CAPITAL LETTER H character (H). The integer represents a duration of that number of hours.

2. A valid non-negative integer[p74] followed by a U+004D LATIN CAPITAL LETTER M character (M). The integer represents a duration of that number of minutes.
3. A valid non-negative integer[p74] followed by a U+0053 LATIN CAPITAL LETTER S character (S). The integer represents a duration of that number of seconds.

5.3.2.1 Conversion to iCalendar §[p799]

Given a list of nodes *nodes* in a `Document`[p127], a user agent must run the following algorithm to **extract any vEvent data represented by those nodes**:

1. If none of the nodes in *nodes* are items[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794], then there is no vEvent data. Abort the algorithm, returning nothing.
2. Let *output* be an empty string.
3. Add an iCalendar line[p799] with the type "`BEGIN`" and the value "`VCALENDAR`" to *output*.
4. Add an iCalendar line[p799] with the type "`PRODID`" and the value equal to a user-agent-specific string representing the user agent to *output*.
5. Add an iCalendar line[p799] with the type "`VERSION`" and the value "`2.0`" to *output*.
6. For each node *node* in *nodes* that is an item[p774] with the type `http://microformats.org/profile/hcalendar#vevent`[p794], run the following steps:
    1. Add an iCalendar line[p799] with the type "`BEGIN`" and the value "`VEVENT`" to *output*.
    2. Add an iCalendar line[p799] with the type "`DTSTAMP`" and a value consisting of an iCalendar DATE-TIME string representing the current date and time, with the annotation "`VALUE=DATE-TIME`", to *output*. [RFC5545][p1416]
    3. For each element *element* that is a property of the item[p779] *node*: for each name *name* in *element*'s property names[p777], run the appropriate set of substeps from the following list:

       If the property's value[p778] is an item[p774]

       Skip the property.

       If the property is `dtend`[p796]
       If the property is `dtstart`[p797]
       If the property is `exdate`[p797]
       If the property is `rdate`[p798]
       If the property is `created`[p798]
       If the property is `last-modified`[p798]

       Let *value* be the result of stripping all U+002D HYPHEN-MINUS (-) and U+003A COLON (:) characters from the property's value[p778].

       If the property's value[p778] is a valid date string[p80] then add an iCalendar line[p799] with the type *name* and the value *value* to *output*, with the annotation "`VALUE=DATE`".

       Otherwise, if the property's value[p778] is a valid global date and time string[p85] then add an iCalendar line[p799] with the type *name* and the value *value* to *output*, with the annotation "`VALUE=DATE-TIME`".

       Otherwise skip the property.

       Otherwise

       Add an iCalendar line[p799] with the type *name* and the property's value[p778] to *output*.
    4. Add an iCalendar line[p799] with the type "`END`" and the value "`VEVENT`" to *output*.
7. Add an iCalendar line[p799] with the type "`END`" and the value "`VCALENDAR`" to *output*.

When the above algorithm says that the user agent is to **add an iCalendar line** consisting of a type *type*, a value *value*, and optionally an annotation, to a string *output*, it must run the following steps:

1. Let *line* be an empty string.
2. Append *type*, converted to ASCII uppercase, to *line*.
3. If there is an annotation:
    1. Append a U+003B SEMICOLON character (;) to *line*.
    2. Append the annotation to *line*.
4. Append a U+003A COLON character (:) to *line*.
5. Prefix every U+005C REVERSE SOLIDUS character (\) in *value* with another U+005C REVERSE SOLIDUS character (\).
6. Prefix every U+002C COMMA character (,) in *value* with a U+005C REVERSE SOLIDUS character (\).
7. Prefix every U+003B SEMICOLON character (;) in *value* with a U+005C REVERSE SOLIDUS character (\).
8. Replace every U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF) in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
9. Replace every remaining U+000D CARRIAGE RETURN (CR) or U+000A LINE FEED (LF) character in *value* with a U+005C REVERSE SOLIDUS character (\) followed by a U+006E LATIN SMALL LETTER N character (n).
10. Append *value* to *line*.
11. Let *maximum length* be 75.
12. While *line*'s code point length is greater than *maximum length*:
    1. Append the first *maximum length* code points of *line* to *output*.
    2. Remove the first *maximum length* code points from *line*.
    3. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
    4. Append a U+000A LINE FEED character (LF) to *output*.
    5. Append a U+0020 SPACE character to *output*.
    6. Let *maximum length* be 74.
13. Append (what remains of) *line* to *output*.
14. Append a U+000D CARRIAGE RETURN character (CR) to *output*.
15. Append a U+000A LINE FEED character (LF) to *output*.

Note

This algorithm can generate invalid iCalendar output, if the input does not conform to the rules described for the `http://microformats.org/profile/hcalendar#vevent` *item type* *and defined property names*.

5.3.2.2 Examples

This section is non-normative.

Example

Here is an example of a page that uses the vEvent vocabulary to mark up an event:

```
<body itemscope itemtype="http://microformats.org/profile/hcalendar#vevent">
 ...
 <h1 itemprop="summary">Bluesday Tuesday: Money Road</h1>
 ...
 <time itemprop="dtstart" datetime="2009-05-05T19:00:00Z">May 5th @ 7pm</time>
 (until <time itemprop="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>)
 ...
```

```
 <a href="http://livebrum.co.uk/2009/05/05/bluesday-tuesday-money-road"
    rel="bookmark" itemprop="url">Link to this page</a>
 ...
 <p>Location: <span itemprop="location">The RoadHouse</span></p>
 ...
 <p><input type=button value="Add to Calendar"
          onclick="location = getCalendar(this)"></p>
 ...
 <meta itemprop="description" content="via livebrum.co.uk">
</body>
```

The `getCalendar()` function is left as an exercise for the reader.

The same page could offer some markup, such as the following, for copy-and-pasting into blogs:

```
<div itemscope itemtype="http://microformats.org/profile/hcalendar#vevent">
 <p>I'm going to
 <strong itemprop="summary">Bluesday Tuesday: Money Road</strong>,
 <time itemprop="dtstart" datetime="2009-05-05T19:00:00Z">May 5th at 7pm</time>
 to <time itemprop="dtend" datetime="2009-05-05T21:00:00Z">9pm</time>,
 at <span itemprop="location">The RoadHouse</span>!</p>
 <p><a href="http://livebrum.co.uk/2009/05/05/bluesday-tuesday-money-road"
       itemprop="url">See this event on livebrum.co.uk</a>.</p>
 <meta itemprop="description" content="via livebrum.co.uk">
</div>
```

5.3.3 Licensing works §[p801] [1]

An item with the item type[p774] **http://n.whatwg.org/work** represents a work (e.g. an article, an image, a video, a song, etc.). This type is primarily intended to allow authors to include licensing information for works.

The following are the type's defined property names[p777].

work

Identifies the work being described.

The value[p778] must be an absolute URL.

Exactly one property with the name `work`[p801] must be present within each item[p774] with the type `http://n.whatwg.org/work`[p801].

title

Gives the name of the work.

A single property with the name `title`[p801] may be present within each item[p774] with the type `http://n.whatwg.org/work`[p801].

author

Gives the name or contact information of one of the authors or creators of the work.

The value[p778] must be either an item[p774] with the type `http://microformats.org/profile/hcard`[p781], or text.

Any number of properties with the name `author`[p801] may be present within each item[p774] with the type `http://n.whatwg.org/work`[p801].

license

Identifies one of the licenses under which the work is available.

The value[p778] must be an absolute URL.

Any number of properties with the name `license`[p801] may be present within each item[p774] with the type `http://n.whatwg.org/`

work[p801].

5.3.3.1 Examples §[p802]

This section is non-normative.

Example

This example shows an embedded image entitled *My Pond*, licensed under the Creative Commons Attribution-Share Alike 4.0 International License and the MIT license simultaneously.

```
<figure itemscope itemtype="http://n.whatwg.org/work">
 <img itemprop="work" src="mypond.jpeg">
 <figcaption>
  <p><cite itemprop="title">My Pond</cite></p>
  <p><small>Licensed under the <a itemprop="license"
  href="https://creativecommons.org/licenses/by-sa/4.0/">Creative
  Commons Attribution-Share Alike 4.0 International License</a>
  and the <a itemprop="license"
  href="http://www.opensource.org/licenses/mit-license.php">MIT
  license</a>.</small>
 </figcaption>
</figure>
```

5.4 Converting HTML to other formats §[p802]

5.4.1 JSON §[p802]

Given a list of nodes *nodes* in a Document[p127], a user agent must run the following algorithm to **extract the microdata from those nodes into a JSON form**:

1. Let *result* be an empty object.
2. Let *items* be an empty array.
3. For each *node* in *nodes*, check if the element is a top-level microdata item[p779], and if it is then get the object[p802] for that element and add it to *items*.
4. Add an entry to *result* called "`items`" whose value is the array *items*.
5. Return the result of serializing *result* to JSON in the shortest possible way (meaning no whitespace between tokens, no unnecessary zero digits in numbers, and only using Unicode escapes in strings for characters that do not have a dedicated escape sequence), and with a lowercase "`e`" used, when appropriate, in the representation of any numbers. [JSON][p1414]

Note

This algorithm returns an object with a single property that is an array, instead of just returning an array, so that it is possible to extend the algorithm in the future if necessary.

When the user agent is to **get the object** for an item *item*, optionally with a list of elements *memory*, it must run the following substeps:

1. Let *result* be an empty object.
2. If no *memory* was passed to the algorithm, let *memory* be an empty list.
3. Add *item* to *memory*.
4. If the *item* has any item types[p774], add an entry to *result* called "`type`" whose value is an array listing the item types[p774] of *item*, in the order they were specified on the `itemtype`[p774] attribute.

5. If the *item* has a global identifier[p775], add an entry to *result* called "`id`" whose value is the global identifier[p775] of *item*.

6. Let *properties* be an empty object.

7. For each element *element* that has one or more property names[p777] and is one of the properties of the item[p779] *item*, in the order those elements are given by the algorithm that returns the properties of an item[p779], run the following substeps:

    1. Let *value* be the property value[p778] of *element*.

    2. If *value* is an item[p774], then: If *value* is in *memory*, then let *value* be the string "`ERROR`". Otherwise, get the object[p802] for *value*, passing a copy of *memory*, and then replace *value* with the object returned from those steps.

    3. For each name *name* in *element*'s property names[p777], run the following substeps:

        1. If there is no entry named *name* in *properties*, then add an entry named *name* to *properties* whose value is an empty array.

        2. Append *value* to the entry named *name* in *properties*.

8. Add an entry to *result* called "`properties`" whose value is the object *properties*.

9. Return *result*.

Example

For example, take this markup:

```
<!DOCTYPE HTML>
<html lang="en">
<title>My Blog</title>
<article itemscope itemtype="http://schema.org/BlogPosting">
 <header>
  <h1 itemprop="headline">Progress report</h1>
  <p><time itemprop="datePublished" datetime="2013-08-29">today</time></p>
  <link itemprop="url" href="?comments=0">
 </header>
 <p>All in all, he's doing well with his swim lessons. The biggest thing was he had trouble
 putting his head in, but we got it down.</p>
 <section>
  <h1>Comments</h1>
  <article itemprop="comment" itemscope itemtype="http://schema.org/UserComments" id="c1">
   <link itemprop="url" href="#c1">
   <footer>
    <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
     <span itemprop="name">Greg</span>
    </span></p>
    <p><time itemprop="commentTime" datetime="2013-08-29">15 minutes ago</time></p>
   </footer>
   <p>Ha!</p>
  </article>
  <article itemprop="comment" itemscope itemtype="http://schema.org/UserComments" id="c2">
   <link itemprop="url" href="#c2">
   <footer>
    <p>Posted by: <span itemprop="creator" itemscope itemtype="http://schema.org/Person">
     <span itemprop="name">Charlotte</span>
    </span></p>
    <p><time itemprop="commentTime" datetime="2013-08-29">5 minutes ago</time></p>
   </footer>
   <p>When you say "we got it down"...</p>
  </article>
 </section>
</article>
```

It would be turned into the following JSON by the algorithm above (supposing that the page's URL was

https://blog.example.com/progress-report):

```
{
  "items": [
    {
      "type": [ "http://schema.org/BlogPosting" ],
      "properties": {
        "headline": [ "Progress report" ],
        "datePublished": [ "2013-08-29" ],
        "url": [ "https://blog.example.com/progress-report?comments=0" ],
        "comment": [
          {
            "type": [ "http://schema.org/UserComments" ],
            "properties": {
              "url": [ "https://blog.example.com/progress-report#c1" ],
              "creator": [
                {
                  "type": [ "http://schema.org/Person" ],
                  "properties": {
                    "name": [ "Greg" ]
                  }
                }
              ],
              "commentTime": [ "2013-08-29" ]
            }
          },
          {
            "type": [ "http://schema.org/UserComments" ],
            "properties": {
              "url": [ "https://blog.example.com/progress-report#c2" ],
              "creator": [
                {
                  "type": [ "http://schema.org/Person" ],
                  "properties": {
                    "name": [ "Charlotte" ]
                  }
                }
              ],
              "commentTime": [ "2013-08-29" ]
            }
          }
        ]
      }
    }
  ]
}
```

6 User interaction §p805

6.1 The hidden p805 attribute §p805

All HTML elements p45 may have the **hidden** content attribute set. The hidden p805 attribute is an enumerated attribute p73. The following table lists the states for this attribute:

State	Keywords
Until found state p805	`until-found`
Hidden state p805	The empty string
	`hidden`

The attribute may be omitted. The *invalid value default* p73 is the hidden state p805. The *missing value default* p73 is the **not hidden state**.

When an element has the hidden p805 attribute in the **hidden state**, it indicates that the element is not yet, or is no longer, directly relevant to the page's current state, or that it is being used to declare content to be reused by other parts of the page as opposed to being directly accessed by the user. User agents should not render elements that are in the hidden state p805. This requirement may be implemented indirectly through the style layer. For example, a web browser could implement these requirements using the rules suggested in the Rendering section p1326.

When an element has the hidden p805 attribute in the **hidden until found state**, it indicates that the element is hidden like the hidden state p805 but the content inside the element will be accessible to find-in-page p840 and fragment navigation p984. When these features attempt to scroll to a target which is in the element's subtree, the user agent will remove the hidden p805 attribute in order to reveal the content before scrolling to it. In addition to removing the hidden p805 attribute, an event named beforematch p1406 is also fired on the element before the hidden p805 attribute is removed.

Web browsers will use 'content-visibility: hidden' instead of 'display: none' when the hidden p805 attribute is in the hidden until found state p805, as specified in the Rendering section p1326.

Note

Because this attribute is typically implemented using CSS, it's also possible to override it using CSS. For instance, a rule that applies 'display: block' to all elements will cancel the effects of the hidden p805 state. Authors therefore have to take care when writing their style sheets to make sure that the attribute is still styled as expected. In addition, legacy user agents which don't support the hidden until found state p805 will have 'display: none' instead of 'content-visibility: hidden', so authors are encouraged to make sure that their style sheets don't change the 'display' or 'content-visibility' properties of hidden until found p805 elements.

Since elements with the hidden p805 attribute in the hidden until found state p805 use 'content-visibility: hidden' instead of 'display: none', there are two caveats of the hidden until found state p805 that make it different from the hidden state p805:

1. *The element needs to be affected by layout containment in order to be revealed by find-in-page. This means that if the element in the hidden until found state p805 has a 'display' value of 'none', 'contents', or 'inline', then the element will not be revealed by find-in-page.*
2. *The element will still have a generated box when in the hidden until found state p805, which means that borders, margin, and padding will still be rendered around the element.*

Example

In the following skeletal example, the attribute is used to hide the web game's main screen until the user logs in:

```
<h1>The Example Game</h1>
<section id="login">
 <h2>Login</h2>
 <form>
  ...
  <!-- calls login() once the user's credentials have been checked -->
 </form>
```

```
  <script>
   function login() {
     // switch screens
     document.getElementById('login').hidden = true;
     document.getElementById('game').hidden = false;
   }
  </script>
 </section>
 <section id="game" hidden>
  ...
 </section>
```

The hidden[p805] attribute must not be used to hide content that could legitimately be shown in another presentation. For example, it is incorrect to use hidden[p805] to hide panels in a tabbed dialog, because the tabbed interface is merely a kind of overflow presentation — one could equally well just show all the form controls in one big page with a scrollbar. It is similarly incorrect to use this attribute to hide content just from one presentation — if something is marked hidden[p805], it is hidden from all presentations, including, for instance, screen readers.

Elements that are not themselves hidden[p805] must not hyperlink[p297] to elements that are hidden[p805]. The `for` attributes of label[p509] and output[p575] elements that are not themselves hidden[p805] must similarly not refer to elements that are hidden[p805]. In both cases, such references would cause user confusion.

Elements and scripts may, however, refer to elements that are hidden[p805] in other contexts.

Example

For example, it would be incorrect to use the href[p297] attribute to link to a section marked with the hidden[p805] attribute. If the content is not applicable or relevant, then there is no reason to link to it.

It would be fine, however, to use the ARIA aria-describedby attribute to refer to descriptions that are themselves hidden[p805]. While hiding the descriptions implies that they are not useful alone, they could be written in such a way that they are useful in the specific context of being referenced from the elements that they describe.

Similarly, a canvas[p661] element with the hidden[p805] attribute could be used by a scripted graphics engine as an off-screen buffer, and a form control could refer to a hidden form[p505] element using its form[p588] attribute.

Elements in a section hidden by the hidden[p805] attribute are still active, e.g. scripts and form controls in such sections still execute and submit respectively. Only their presentation to the user changes.

The **hidden** getter steps are:

1. If the hidden[p805] attribute is in the until-found[p805] state, then return "until-found[p805]".
2. If the hidden[p805] attribute is set, then return true.
3. Return false.

The hidden[p806] setter steps are:

1. If the given value is a string that is an ASCII case-insensitive match for "until-found[p805]", then set the hidden[p805] attribute to "until-found[p805]".
2. Otherwise, if the given value is false, then remove the hidden[p805] attribute.
3. Otherwise, if the given value is the empty string, then remove the hidden[p805] attribute.
4. Otherwise, if the given value is null, then remove the hidden[p805] attribute.
5. Otherwise, if the given value is 0, then remove the hidden[p805] attribute.
6. Otherwise, if the given value is NaN, then remove the hidden[p805] attribute.
7. Otherwise, set the hidden[p805] attribute to the empty string.

The **ancestor hidden-until-found revealing algorithm** is to run the following steps on *currentNode*:

1. While *currentNode* has a parent node within the flat tree:
    1. If *currentNode* has the `hidden` attribute in the hidden until found state, then:
        1. Fire an event named `beforematch` at *currentNode*.
        2. Remove the `hidden` attribute from *currentNode*.
    2. Set *currentNode* to the parent node of *currentNode* within the flat tree.

6.2 Page visibility

A traversable navigable's system visibility state, including its initial value upon creation, is determined by the user agent. It represents, for example, whether the browser window is minimized, a browser tab is currently in the background, or a system element such as a task switcher obscures the page.

When a user-agent determines that the system visibility state for traversable navigable *traversable* has changed to *newState*, it must run the following steps:

1. Let *navigables* be the inclusive descendant navigables of *traversable*.
2. For each *navigable* of *navigables* in what order?:
    1. Let *document* be *navigable*'s active document.
    2. Queue a global task on the user interaction task source given *document*'s relevant global object to update the visibility state of *document* with *newState*.

A `Document` has a **visibility state**, which is either "`hidden`" or "`visible`", initially set to "`hidden`".

The **`visibilityState`** getter steps are to return this's visibility state.

The **`hidden`** getter steps are to return true if this's visibility state is "`hidden`", otherwise false.

To **update the visibility state** of `Document` *document* to *visibilityState*:

1. If *document*'s visibility state equals *visibilityState*, then return.
2. Set *document*'s visibility state to *visibilityState*.
3. Queue a new `VisibilityStateEntry` whose visibility state is *visibilityState* and whose timestamp is the current high resolution time given *document*'s relevant global object.
4. Run the screen orientation change steps with *document*. [SCREENORIENTATION]
5. Run any **page visibility change steps** which may be defined in other specifications, with visibility state and *document*.

    It would be better if specification authors sent a pull request to add calls from here into their specifications directly, instead of using the page visibility change steps hook, to ensure well-defined cross-specification call order. As of the time of this writing the following specifications are known to have page visibility change steps, which will be run in an unspecified order: *Device Posture API* and *Web NFC*. [DEVICEPOSTURE] [WEBNFC]

6. Fire an event named `visibilitychange` at *document*, with its `bubbles` attribute initialized to true.

6.2.1 The `VisibilityStateEntry` interface

The `VisibilityStateEntry` interface exposes visibility changes to the document, from the moment the document becomes active.

Example

For example, this allows JavaScript code in the page to examine correlation between visibility changes and paint timing:

```
function wasHiddenBeforeFirstContentfulPaint() {
    const fcpEntry = performance.getEntriesByName("first-contentful-paint")[0];
    const visibilityStateEntries = performance.getEntriesByType("visibility-state");
    return visibilityStateEntries.some(e =>
                                            e.startTime < fcpEntry.startTime &&
                                            e.name === "hidden");
}
```

Note

Since hiding a page can cause throttling of rendering and other user-agent operations, it is common to use visibility changes as an indication that such throttling has occurred. However, other things could also cause throttling in different browsers, such as long periods of inactivity.

IDL

```
[Exposed=(Window)]
interface VisibilityStateEntry : PerformanceEntry {
  readonly attribute DOMString name;                 // shadows inherited name
  readonly attribute DOMString entryType;            // shadows inherited entryType
  readonly attribute DOMHighResTimeStamp startTime;  // shadows inherited startTime
  readonly attribute unsigned long duration;         // shadows inherited duration
};
```

The VisibilityStateEntry[p808] has an associated DOMHighResTimeStamp **timestamp**.

The VisibilityStateEntry[p808] has an associated "visible" or "hidden" **visibility state**.

The **name** getter steps are to return this's visibility state[p808].

The **entryType** getter steps are to return "visibility-state".

The **startTime** getter steps are to return this's timestamp[p808].

The **duration** getter steps are to return zero.

6.3 Inert subtrees §[p808]

Note

See also inert[p809] for an explanation of the attribute of the same name.

A node (in particular elements and text nodes) can be **inert**. When a node is inert[p808]:

- Hit-testing must act as if the 'pointer-events' CSS property were set to 'none'.
- Text selection functionality must act as if the 'user-select' CSS property were set to 'none'.
- If it is editable, the node behaves as if it were non-editable.
- The user agent should ignore the node for the purposes of find-in-page[p840].

Note

Inert nodes generally cannot be focused, and user agents do not expose the inert nodes to accessibility APIs or assistive technologies. Inert nodes that are commands[p630] will become inoperable to users, in the manner described above.

User agents may allow the user to override the restrictions on find-in-page[p840] and text selection, however.

By default, a node is not inert[p808].

6.3.1 Modal dialogs and inert subtrees §[p809]

A Document[p127] *document* is **blocked by a modal dialog** *subject* if *subject* is the topmost dialog[p633] element in *document*'s top layer. While *document* is so blocked, every node that is connected to *document*, with the exception of the *subject* element and its flat tree descendants, must become inert[p808].

subject can additionally become inert[p808] via the inert[p809] attribute, but only if specified on *subject* itself (i.e., *subject* escapes inertness of ancestors); *subject*'s flat tree descendants can become inert[p808] in a similar fashion.

Note

The dialog[p633] *element's* showModal()[p636] *method causes this mechanism to trigger, by adding the* dialog[p633] *element to its node document's top layer.*

6.3.2 The inert attribute §[p809]

The inert[p809] attribute is a boolean attribute[p72] that indicates, by its presence, that the element and all its flat tree descendants which don't otherwise escape inertness (such as modal dialogs) are to be made inert[p808] by the user agent.

An inert subtree should not contain any content or controls which are critical to understanding or using aspects of the page which are not in the inert state. Content in an inert subtree will not be perceivable by all users, or interactive. Authors should not specify elements as inert unless the content they represent are also visually obscured in some way. In most cases, authors should not specify the inert[p808] attribute on individual form controls. In these instances, the disabled[p591] attribute is probably more appropriate.

Example

The following example shows how to mark partially loaded content, visually obscured by a "loading" message, as inert.

```
<section aria-labelledby=s1>
  <h3 id=s1>Population by City</h3>
  <div class=container>
    <div class=loading><p>Loading...</p></div>
    <div inert>
      <form>
        <fieldset>
          <legend>Date range</legend>
          <div>
            <label for=start>Start</label>
            <input type=date id=start>
          </div>
          <div>
            <label for=end>End</label>
            <input type=date id=end>
          </div>
          <div>
            <button>Apply</button>
          </div>
        </fieldset>
      </form>
      <table>
        <caption>From 20-- to 20--</caption>
        <thead>
          <tr>
            <th>City</th>
            <th>State</th>
            <th>20-- Population</th>
            <th>20-- Population</th>
            <th>Percentage change</th>
          </tr>
        </thead>
        <tbody>
```

```
          <!-- ... -->
        </tbody>
      </table>
    </div>
  </div>
</section>
```

The "loading" overlay obscures the inert content, making it visually apparent that the inert content is not presently accessible. Notice that the heading and "loading" text are not descendants of the element with the `inert`[p808] attribute. This will ensure this text is accessible to all users, while the inert content cannot be interacted with by anyone.

Note

By default, there is no persistent visual indication of an element or its subtree being inert. Appropriate visual styles for such content is often context-dependent. For instance, an inert off-screen navigation panel would not require a default style, as its off-screen position visually obscures the content. Similarly, a modal `dialog`[p633] element's backdrop will serve as the means to visually obscure the inert content of the web page, rather than styling the inert content specifically.

However, for many other situations authors are strongly encouraged to clearly mark what parts of their document are active and which are inert, to avoid user confusion. In particular, it is worth remembering that not all users can see all parts of a page at once; for example, users of screen readers, users on small devices or with magnifiers, and even users using particularly small windows might not be able to see the active part of a page and might get frustrated if inert sections are not obviously inert.

The **`inert`** IDL attribute must reflect[p101] the content attribute of the same name.

✔ MDN

6.4 Tracking user activation §[p81] 0

To prevent abuse of certain APIs that could be annoying to users (e.g., opening popups or vibrating phones), user agents allow these APIs only when the user is actively interacting with the web page or has interacted with the page at least once. This "active interaction" state is maintained through the mechanisms defined in this section.

6.4.1 Data model §[p81] 0

For the purpose of tracking user activation, each `Window`[p892] *W* has two relevant values:

- A **last activation timestamp**, which is either a `DOMHighResTimeStamp`, positive infinity (indicating that *W* has never been activated), or negative infinity (indicating that the activation has been consumed[p812]). Initially positive infinity.
- A **last history-action activation timestamp**, which is either a `DOMHighResTimeStamp` or positive infinity, initially positive infinity.

A user agent also defines a **transient activation duration**, which is a constant number indicating how long a user activation is available for certain user activation-gated APIs[p812] (e.g., for opening popups).

Note

The transient activation duration[p810] is expected be at most a few seconds, so that the user can possibly perceive the link between an interaction with the page and the page calling the activation-gated API.

We then have the following boolean user activation states for *W*:

Sticky activation

When the current high resolution time given *W* is greater than or equal to the last activation timestamp[p810] in *W*, *W* is said to have sticky activation[p811].

This is *W*'s historical activation state, indicating whether the user has ever interacted in *W*. It starts false, then changes to true (and never changes back to false) when *W* gets the very first activation notification[p811].

Transient activation

When the current high resolution time given *W* is greater than or equal to the last activation timestamp[p810] in *W*, and less than the last activation timestamp[p810] in *W* plus the transient activation duration[p810], then *W* is said to have transient activation[p811].

This is *W*'s current activation state, indicating whether the user has interacted in *W* recently. This starts with a false value, and remains true for a limited time after every activation notification[p811] *W* gets.

The transient activation[p811] state is considered **expired** if it becomes false because the transient activation duration[p810] time has elapsed since the last user activation. Note that it can become false even before the expiry time through an activation consumption[p812].

History-action activation

When the last history-action activation timestamp[p810] of *W* is not equal to the last activation timestamp[p810] of *W*, then *W* is said to have history-action activation[p811].

This is a special variant of user activation, used to allow access to certain session history APIs which, if used too frequently, would make it harder for the user to traverse back using browser UI[p1026]. It starts with a false value, and becomes true whenever the user interacts with *W*, but is reset to false through history-action activation consumption[p812]. This ensures such APIs cannot be used multiple times in a row without an intervening user activation. But unlike transient activation[p811], there is no time limit within which such APIs must be used.

Note

The last activation timestamp[p810] and last history-action activation timestamp[p810] are retained even after the `Document`[p127] changes its fully active[p966] status (e.g., after navigating away from a `Document`[p127], or navigating to a cached `Document`[p127]). This means sticky activation[p811] state spans multiple navigations as long as the same `Document`[p127] gets reused. For the transient activation state, the original expiry[p811] time remains unchanged (i.e., the state still expires within the transient activation duration[p810] limit from the original activation triggering input event[p811]). It is important to consider this when deciding whether to base certain things off sticky activation[p811] or transient activation[p811].

6.4.2 Processing model §[p811] 1

When a user interaction causes firing of an activation triggering input event[p811] in a `Document`[p127] *document*, the user agent must perform the following **activation notification** steps *before* dispatching the event:

1. Assert: *document* is fully active[p966].
2. Let *windows* be « *document*'s relevant global object[p1039] ».
3. Extend *windows* with the active window[p952] of each of *document*'s ancestor navigables[p957].
4. Extend *windows* with the active window[p952] of each of *document*'s descendant navigables[p957], filtered to include only those navigables[p952] whose active document[p952]'s origin is same origin[p870] with *document*'s origin.
5. For each *window* in *windows*, set *window*'s last activation timestamp[p810] to the current high resolution time.

An **activation triggering input event** is any event whose `isTrusted` attribute is true and whose `type` is one of:

- "`keydown`", provided the key is neither the Esc key nor a shortcut key reserved by the user agent.

- "mousedown".
- "pointerdown", provided the event's pointerType is "mouse".
- "pointerup", provided the event's pointerType is not "mouse".
- "touchend".

Activation consuming APIs[p812] defined in this and other specifications can **consume user activation** by performing the following steps, given a Window[p892] *W*:

1. If *W*'s navigable[p894] is null, then return.
2. Let *top* be *W*'s navigable[p894]'s top-level traversable[p954].
3. Let *navigables* be the inclusive descendant navigables[p957] of *top*'s active document[p952].
4. Let *windows* be the list of Window[p892] objects constructed by taking the active window[p952] of each item in *navigables*.
5. For each *window* in *windows*, if *window*'s last activation timestamp[p810] is not positive infinity, then set *window*'s last activation timestamp[p810] to negative infinity.

History-action activation-consuming APIs[p812] can **consume history-action user activation** by performing the following steps, given a Window[p892] *W*:

1. If *W*'s navigable[p894] is null, then return.
2. Let *top* be *W*'s navigable[p894]'s top-level traversable[p954].
3. Let *navigables* be the inclusive descendant navigables[p957] of *top*'s active document[p952].
4. Let *windows* be the list of Window[p892] objects constructed by taking the active window[p952] of each item in *navigables*.
5. For each *window* in *windows*, set *window*'s last history-action activation timestamp[p810] to *window*'s *window*'s last activation timestamp[p810].

Note

Note the asymmetry in the sets of browsing contexts[p961] in the page that are affected by an activation notification[p811] vs an activation consumption[p812]: an activation consumption changes (to false) the transient activation[p811] states for all browsing contexts in the page, but an activation notification changes (to true) the states for a subset of those browsing contexts. The exhaustive nature of consumption here is deliberate: it prevents malicious sites from making multiple calls to an activation consuming API[p812] from a single user activation (possibly by exploiting a deep hierarchy of iframe[p383]s).

6.4.3 APIs gated by user activation §[p812]

APIs that are dependent on user activation are classified into different levels:

Sticky activation-gated APIs

These APIs require the sticky activation[p811] state to be true, so they are blocked until the very first user activation.

Transient activation-gated APIs

These APIs require the transient activation[p811] state to be true, but they don't consume[p812] it, so multiple calls are allowed per user activation until the transient state expires[p811].

Transient activation-consuming APIs

These APIs require the transient activation[p811] state to be true, and they consume user activation[p812] in each call to prevent multiple calls per user activation.

History-action activation-consuming APIs

These APIs require the history-action activation[p811] state to be true, and they consume history-action user activation[p812] in each call to prevent multiple calls per user activation.

6.4.4 The UserActivation[p813] interface §[p813]

Each Window[p892] has an **associated UserActivation**, which is a UserActivation[p813] object. Upon creation of the Window[p892] object, its associated UserActivation[p813] must be set to a new UserActivation[p813] object created in the Window[p892] object's relevant realm[p1039].

IDL
```
[Exposed=Window]
interface UserActivation {
  readonly attribute boolean hasBeenActive;
  readonly attribute boolean isActive;
};

partial interface Navigator {
  [SameObject] readonly attribute UserActivation userActivation;
};
```

For web developers (non-normative)

navigator[p1109].userActivation[p813].hasBeenActive[p813]

Returns whether the window has sticky activation[p811].

navigator[p1109].userActivation[p813].isActive[p813]

Returns whether the window has transient activation[p811].

The **userActivation** getter steps are to return this's relevant global object[p1039]'s associated UserActivation[p813].

The **hasBeenActive** getter steps are to return true if this's relevant global object[p1039] has sticky activation[p811], and false otherwise.

The **isActive** getter steps are to return true if this's relevant global object[p1039] has transient activation[p811], and false otherwise.

6.4.5 User agent automation §[p813]

For the purposes of user-agent automation and application testing, this specification defines the following extension command for the *Web Driver* specification. It is optional for a user agent to support the following extension command. [WEBDRIVER][p1418]

HTTP Method	URI Template
`POST`	`/session/{session id}/window/consume-user-activation`

The remote end steps are:

1. Let *window* be current browsing context's active window[p961].
2. Let *consume* be true if *window* has transient activation[p811]; otherwise false.
3. If *consume* is true, then consume user activation[p812] of *window*.
4. Return success with data *consume*.

6.5 Activation behavior of elements §[p813]

Certain elements in HTML have an activation behavior, which means that the user can activate them. This is always caused by a `click` event.

The user agent should allow the user to manually trigger elements that have an activation behavior, for instance using keyboard or voice input, or through mouse clicks. When the user triggers an element with a defined activation behavior in a manner other than clicking it, the default action of the interaction event must be to fire a `click` event[p1094] at the element.

For web developers (non-normative)

***element*.click[p814]()**

Acts as if the element was clicked.

Each element has an associated **click in progress flag**, which is initially unset.

The `click()` method must run the following steps:

1. If this element is a form control that is disabled[p592], then return.
2. If this element's click in progress flag[p814] is set, then return.
3. Set this element's click in progress flag[p814].
4. Fire a synthetic pointer event[p1094] named `click` at this element, with the *not trusted flag* set.
5. Unset this element's click in progress flag[p814].

6.6 Focus §[p81 4]

6.6.1 Introduction §[p81 4]

This section is non-normative.

An HTML user interface typically consists of multiple interactive widgets, such as form controls, scrollable regions, links, dialog boxes, browser tabs, and so forth. These widgets form a hierarchy, with some (e.g. browser tabs, dialog boxes) containing others (e.g. links, form controls).

When interacting with an interface using a keyboard, key input is channeled from the system, through the hierarchy of interactive widgets, to an active widget, which is said to be focused[p817].

Example

Consider an HTML application running in a browser tab running in a graphical environment. Suppose this application had a page with some text controls and links, and was currently showing a modal dialog, which itself had a text control and a button.

The hierarchy of focusable widgets, in this scenario, would include the browser window, which would have, amongst its children, the browser tab containing the HTML application. The tab itself would have as its children the various links and text controls, as well as the dialog. The dialog itself would have as its children the text control and the button.

If the widget with focus[p817] in this example was the text control in the dialog box, then key input would be channeled from the graphical system to ① the web browser, then to ② the tab, then to ③ the dialog, and finally to ④ the text control.

Keyboard *events* are always targeted at this focused[p817] element.

6.6.2 Data model §[p815]

A top-level traversable[p953] has **system focus** when it can receive keyboard input channeled from the operating system, possibly targeted at one of its active document[p952]'s descendant navigables[p957].

A top-level traversable[p953] has **user attention** when its system visibility state[p953] is "`visible`", and it either has system focus[p815] or user agent widgets directly related to it can receive keyboard input channeled from the operating system.

Note

User attention is lost when a browser window loses focus, whereas system focus might also be lost to other system widgets in the browser window such as a location bar.

A `Document`[p127] *d* is a **fully active descendant of a top-level traversable with user attention** when *d* is fully active[p966] and *d*'s node navigable[p953]'s top-level traversable[p954] has user attention[p815].

The term **focusable area** is used to refer to regions of the interface that can further become the target of such keyboard input. Focusable areas can be elements, parts of elements, or other regions managed by the user agent.

Each focusable area[p815] has a **DOM anchor**, which is a `Node` object that represents the position of the focusable area[p815] in the DOM. (When the focusable area[p815] is itself a `Node`, it is its own DOM anchor[p815].) The DOM anchor[p815] is used in some APIs as a substitute for the focusable area[p815] when there is no other DOM object to represent the focusable area[p815].

The following table describes what objects can be focusable areas[p815]. The cells in the left column describe objects that can be focusable areas[p815]; the cells in the right column describe the DOM anchors[p815] for those elements. (The cells that span both columns are non-normative examples.)

Focusable area[p815]	DOM anchor[p815]
Examples	
Elements that meet all the following criteria: • **the element's tabindex value[p820] is non-null, or the element is determined by the user agent to be focusable;** • **the element is either not a shadow host, or has a shadow root whose delegates focus is false;** • **the element is not actually disabled[p763];** • **the element is not inert[p808];** • **the element is either being rendered[p1325] or being used as relevant canvas fallback content[p662].**	The element itself.

Example

`iframe`[p383], `dialog`[p633], `<input type=text>`[p519], sometimes `<a href="">`[p252] (depending on platform conventions).

The shapes of `area`[p463] elements in an image map[p464] associated with an `img`[p338] element that is being rendered[p1325] and is not inert[p808].	The `img`[p338] element.

Example

In the following example, the `area`[p463] element creates two shapes, one on each image. The DOM anchor[p815] of the first shape is the first `img`[p338] element, and the DOM anchor[p815] of the second shape is the second `img`[p338] element.

```
<map id=wallmap><area alt="Enter Door" coords="10,10,100,200" href="door.html"></map>
...
<img src="images/innerwall.jpeg" alt="There is a white wall here, with a door." usemap="#wallmap">
...
<img src="images/outerwall.jpeg" alt="There is a red wall here, with a door." usemap="#wallmap">
```

The user-agent provided subwidgets of elements that are being rendered[p1325] and are not actually disabled[p763] or inert[p808].	The element for which the focusable area[p815] is a subwidget.

Example

The controls in the user interface[p455] for a `video`[p398] element, the up and down buttons in a spin-control version of `<input type=number>`[p528], the part of a `details`[p627] element's rendering that enables the element to be opened or closed using keyboard input.

The scrollable regions of elements that are being rendered[p1325] and are not inert[p808].	The element for which the box that the scrollable region scrolls was created.

Example

The CSS 'overflow' property's 'scroll' value typically creates a scrollable region.

The viewport of a `Document`[p127] that has a non-null browsing context[p961] and is not inert[p808].	The `Document`[p127] for which the viewport was created.

Example

The contents of an `iframe`[p383].

Any other element or part of an element determined by the user agent to be a focusable area, especially to aid with accessibility or to better match platform conventions.	The element.

Example

A user agent could make all list item bullets sequentially focusable[p817], so that a user can more easily navigate lists.

Example

Similarly, a user agent could make all elements with `title`[p154] attributes sequentially focusable[p817], so that their advisory information can be accessed.

Note

A navigable container[p955] (e.g. an `iframe`[p383]) is a focusable area[p815], but key events routed to a navigable container[p955] get immediately routed to its content navigable[p955]'s active document[p952]. Similarly, in sequential focus navigation a navigable container[p955] essentially acts merely as a placeholder for its content navigable[p955]'s active document[p952].

One focusable area[p815] in each Document[p127] is designated the **focused area of the document**. Which control is so designated changes over time, based on algorithms in this specification.

Note

Even if a document is not fully active[p966] and not shown to the user, it can still have a focused area of the document[p817]. If a document's fully active[p966] state changes, its focused area of the document[p817] will stay the same.

The **currently focused area of a top-level traversable** *traversable* is the focusable area[p815]-or-null returned by this algorithm:

1. If *traversable* does not have system focus[p815], then return null.
2. Let *candidate* be *traversable*'s active document[p961].
3. While *candidate*'s focused area[p817] is a navigable container[p955] with a non-null content navigable[p955]: set *candidate* to the active document[p952] of that navigable container[p955]'s content navigable[p955].
4. If *candidate*'s focused area[p817] is non-null, set *candidate* to *candidate*'s focused area[p817].
5. Return *candidate*.

The **current focus chain of a top-level traversable** *traversable* is the focus chain[p817] of the currently focused area[p817] of *traversable*, if *traversable* is non-null, or an empty list otherwise.

An element that is the DOM anchor[p815] of a focusable area[p815] is said to **gain focus** when that focusable area[p815] becomes the currently focused area of a top-level traversable[p817]. When an element is the DOM anchor[p815] of a focusable area[p815] of the currently focused area of a top-level traversable[p817], it is **focused**.

The **focus chain** of a focusable area[p815] *subject* is the ordered list constructed as follows:

1. Let *output* be an empty list.
2. Let *currentObject* be *subject*.
3. While true:
    1. Append *currentObject* to *output*.
    2. If *currentObject* is an area[p463] element's shape, then append that area[p463] element to *output*.

       Otherwise, if *currentObject*'s DOM anchor[p815] is an element that is not *currentObject* itself, then append *currentObject*'s DOM anchor[p815] to *output*.
    3. If *currentObject* is a focusable area[p815], then set *currentObject* to *currentObject*'s DOM anchor[p815]'s node document.

       Otherwise, if *currentObject* is a Document[p127] whose node navigable[p953]'s parent[p952] is non-null, then set *currentObject* to *currentObject*'s node navigable[p953]'s parent[p952].

       Otherwise, break.
4. Return *output*.

Note

The chain starts with subject *and (if* subject *is or can be the currently focused area of a top-level traversable[p817]) continues up the focus hierarchy up to the* Document[p127] *of the top-level traversable[p953].*

All elements that are focusable areas[p815] are said to be **focusable**.

There are two special types of focusability for focusable areas[p815]:

- A focusable area[p815] is said to be **sequentially focusable** if it is included in its Document[p127]'s sequential focus navigation order[p825] and the user agent determines that it is sequentially focusable.
- A focusable area[p815] is said to be **click focusable** if the user agent determines that it is click focusable. User agents should consider focusable areas with non-null tabindex values[p820] to be click focusable.

Note

Elements which are not focusable[p817] are not focusable areas[p815], and thus not sequentially focusable[p817] and not click focusable[p817].

Note

Being focusable[p817] is a statement about whether an element can be focused programmatically, e.g. via the `focus()`[p828] method or `autofocus`[p828] attribute. In contrast, sequentially focusable[p817] and click focusable[p817] govern how the user agent responds to user interaction: respectively, to sequential focus navigation[p825] and as activation behavior[p0].

The user agent might determine that an element is not sequentially focusable[p817] even if it is focusable[p817] and is included in its `Document`[p127]'s sequential focus navigation order[p825], according to user preferences. For example, macOS users can set the user agent to skip non-form control elements, or can skip links when doing sequential focus navigation[p825] with just the Tab key (as opposed to using both the `Option` and Tab keys).

Similarly, the user agent might determine that an element is not click focusable[p817] even if it is focusable[p817]. For example, in some user agents, clicking on a non-editable form control does not focus it, i.e. the user agent has determined that such controls are not click focusable.

Thus, an element can be focusable[p817], but neither sequentially focusable[p817] nor click focusable[p817]. For example, in some user agents, a non-editable form-control with a negative-integer tabindex value[p820] would not be focusable via user interaction, only via programmatic APIs.

When a user activates[p813] a click focusable[p817] focusable area[p815], the user agent must run the focusing steps[p822] on the focusable area[p815] with *focus trigger* set to "`click`".

Note

Note that focusing is not an activation behavior, i.e. calling the `click()`[p814] method on an element or dispatching a synthetic `click` event on it won't cause the element to get focused.

A node is a **focus navigation scope owner** if it is a `Document`[p127], a shadow host, a slot[p659], or an element in the popover showing state[p859] which also has a popover invoker[p859] set.

Each focus navigation scope owner[p818] has a **focus navigation scope**, which is a list of elements. Its contents are determined as follows:

Every element *element* has an **associated focus navigation owner**, which is either null or a focus navigation scope owner[p818]. It is determined by the following algorithm:

1. If *element*'s parent is null, then return null.
2. If *element*'s parent is a shadow host, then return *element*'s assigned slot.
3. If *element*'s parent is a shadow root, then return the parent's host.
4. If *element*'s parent is the document element, then return the parent's node document.
5. If *element* is in the popover showing state[p859] and has a popover invoker[p859] set, then return *element*.
6. Return *element*'s parent's associated focus navigation owner[p818].

Then, the contents of a given focus navigation scope owner[p818] *owner*'s focus navigation scope[p818] are all elements whose associated focus navigation owner[p818] is *owner*.

Note

The order of elements within a focus navigation scope[p818] does not impact any of the algorithms in this specification. Ordering only becomes important for the tabindex-ordered focus navigation scope[p818] and flattened tabindex-ordered focus navigation scope[p819] concepts defined below.

A **tabindex-ordered focus navigation scope** is a list of focusable areas[p815] and focus navigation scope owners[p818]. Every focus navigation scope owner[p818] *owner* has tabindex-ordered focus navigation scope[p818], whose contents are determined as follows:

- It contains all elements in *owner*'s focus navigation scope[p818] that are themselves focus navigation scope owners[p818], except the elements whose tabindex value[p820] is a negative integer.
- It contains all of the focusable areas[p815] whose DOM anchor[p815] is an element in *owner*'s focus navigation scope[p818], except the focusable areas[p815] whose tabindex value[p820] is a negative integer.

The order within a tabindex-ordered focus navigation scope[p818] is determined by each element's tabindex value[p820], as described in the section below.

Note

The rules there do not give a precise ordering, as they are composed mostly of "should" statements and relative orderings.

A **flattened tabindex-ordered focus navigation scope** is a list of focusable areas[p815]. Every focus navigation scope owner[p818] *owner* owns a distinct flattened tabindex-ordered focus navigation scope[p819], whose contents are determined by the following algorithm:

1. Let *result* be a clone of *owner*'s tabindex-ordered focus navigation scope[p818].
2. For each *item* of *result*:
    1. If *item* is not a focus navigation scope owner[p818], then continue.
    2. If *item* is not a focusable area[p815], then replace *item* with all of the items in *item*'s flattened tabindex-ordered focus navigation scope[p819].
    3. Otherwise, insert the contents of *item*'s flattened tabindex-ordered focus navigation scope[p819] after *item*.

6.6.3 The `tabindex`[p819] attribute §[p819]

The **`tabindex`** content attribute allows authors to make an element and regions that have the element as its DOM anchor[p815] be focusable areas[p815], allow or prevent them from being sequentially focusable[p817], and determine their relative ordering for sequential focus navigation[p825].

The name "tab index" comes from the common use of the Tab key to navigate through the focusable elements. The term "tabbing" refers to moving forward through sequentially focusable[p817] focusable areas[p815].

The `tabindex`[p819] attribute, if specified, must have a value that is a valid integer[p74]. Positive numbers specify the relative position of the element's focusable areas[p815] in the sequential focus navigation order[p825], and negative numbers indicate that the control is not sequentially focusable[p817].

Developers should use caution when using values other than 0 or −1 for their `tabindex`[p819] attributes as this is complicated to do correctly.

Note

The following provides a non-normative summary of the behaviors of the possible `tabindex`[p819] attribute values. The below processing model gives the more precise rules.

omitted (or non-integer values)

The user agent will decide whether the element is focusable[p817], and if it is, whether it is sequentially focusable[p817] or click focusable[p817] (or both).

−1 (or other negative integer values)

Causes the element to be focusable[p817], and indicates that the author would prefer the element to be click focusable[p817] but not sequentially focusable[p817]. The user agent might ignore this preference for click and sequential focusability, e.g., for specific element types according to platform conventions, or for keyboard-only users.

0

Causes the element to be focusable[p817], and indicates that the author would prefer the element to be both click focusable[p817] and sequentially focusable[p817]. The user agent might ignore this preference for click and sequential focusability.

positive integer values

Behaves the same as 0, but in addition creates a relative ordering within a tabindex-ordered focus navigation scope[p818], so that

elements with higher tabindex[p819] attribute value come later.

Note that the tabindex[p819] attribute cannot be used to make an element non-focusable. The only way a page author can do that is by disabling[p763] the element, or making it inert[p808].

The **tabindex value** of an element is the value of its tabindex[p819] attribute, parsed using the rules for parsing integers[p74]. If parsing fails or the attribute is not specified, then the tabindex value[p820] is null.

The tabindex value[p820] of a focusable area[p815] is the tabindex value[p820] of its DOM anchor[p815].

The tabindex value[p820] of an element must be interpreted as follows:

If the value is null

The user agent should follow platform conventions to determine if the element should be considered as a focusable area[p815] and if so, whether the element and any focusable areas[p815] that have the element as their DOM anchor[p815] are sequentially focusable[p817], and if so, what their relative position in their tabindex-ordered focus navigation scope[p818] is to be. If the element is a focus navigation scope owner[p818], it must be included in its tabindex-ordered focus navigation scope[p818] even if it is not a focusable area[p815].

The relative ordering within a tabindex-ordered focus navigation scope[p818] for elements and focusable areas[p815] that belong to the same focus navigation scope[p818] and whose tabindex value[p820] is null should be in shadow-including tree order.

Modulo platform conventions, it is suggested that the following elements should be considered as focusable areas[p815] and be sequentially focusable[p817]:

- a[p252] elements that have an href[p297] attribute
- button[p556] elements
- input[p512] elements whose type[p514] attribute are not in the Hidden[p518] state
- select[p559] elements
- textarea[p570] elements
- summary[p630] elements that are the first summary[p630] element child of a details[p627] element
- Elements with a draggable[p856] attribute set, if that would enable the user agent to allow the user to begin drag operations for those elements without the use of a pointing device
- Editing hosts[p835]
- Navigable containers[p955]

If the value is a negative integer

The user agent must consider the element as a focusable area[p815], but should omit the element from any tabindex-ordered focus navigation scope[p818].

Note

One valid reason to ignore the requirement that sequential focus navigation not allow the author to lead to the element would be if the user's only mechanism for moving the focus is sequential focus navigation. For instance, a keyboard-only user would be unable to click on a text control with a negative tabindex[p819], so that user's user agent would be well justified in allowing the user to tab to the control regardless.

If the value is a zero

The user agent must allow the element to be considered as a focusable area[p815] and should allow the element and any focusable areas[p815] that have the element as their DOM anchor[p815] to be sequentially focusable[p817].

The relative ordering within a tabindex-ordered focus navigation scope[p818] for elements and focusable areas[p815] that belong to the same focus navigation scope[p818] and whose tabindex value[p820] is zero should be in shadow-including tree order.

If the value is greater than zero

The user agent must allow the element to be considered as a focusable area[p815] and should allow the element and any focusable areas[p815] that have the element as their DOM anchor[p815] to be sequentially focusable[p817], and should place the element — referenced as *candidate* below — and the aforementioned focusable areas[p815] in the tabindex-ordered focus navigation scope[p818] where the element is a part of so that, relative to other elements and focusable areas[p815] that belong to the same focus navigation scope[p818], they are:

- before any focusable area[p815] whose DOM anchor[p815] is an element whose `tabindex`[p819] attribute has been omitted or whose value, when parsed, returns an error,
- before any focusable area[p815] whose DOM anchor[p815] is an element whose `tabindex`[p819] attribute has a value equal to or less than zero,
- after any focusable area[p815] whose DOM anchor[p815] is an element whose `tabindex`[p819] attribute has a value greater than zero but less than the value of the `tabindex`[p819] attribute on *candidate*,
- after any focusable area[p815] whose DOM anchor[p815] is an element whose `tabindex`[p819] attribute has a value equal to the value of the `tabindex`[p819] attribute on *candidate* but that is located earlier than *candidate* in shadow-including tree order,
- before any focusable area[p815] whose DOM anchor[p815] is an element whose `tabindex`[p819] attribute has a value equal to the value of the `tabindex`[p819] attribute on *candidate* but that is located later than *candidate* in shadow-including tree order, and
- before any focusable area[p815] whose DOM anchor[p815] is an element whose `tabindex`[p819] attribute has a value greater than the value of the `tabindex`[p819] attribute on *candidate*.

The **`tabIndex`** IDL attribute must reflect[p101] the value of the `tabindex`[p819] content attribute. The default value[p104] is 0 if the element is an `a`[p252], `area`[p463], `button`[p556], `frame`[p1369], `iframe`[p383], `input`[p512], `object`[p394], `select`[p559], `textarea`[p570], or SVG a element, or is a `summary`[p630] element that is a summary for its parent details[p630]. The default value[p104] is −1 otherwise.

Note

The varying default value based on element type is a historical artifact.

6.6.4 Processing model §[p821]

To **get the focusable area** for a *focus target* that is either an element that is not a focusable area[p815], or is a navigable[p952], given an optional string *focus trigger* (default "`other`"), run the first matching set of steps from the following list:

↪ **If *focus target* is an `area`[p463] element with one or more shapes that are focusable areas[p815]**

Return the shape corresponding to the first `img`[p338] element in tree order that uses the image map to which the `area`[p463] element belongs.

↪ **If *focus target* is an element with one or more scrollable regions that are focusable areas[p815]**

Return the element's first scrollable region, according to a pre-order, depth-first traversal of the flat tree. [CSSSCOPING][p1412]

↪ **If *focus target* is the document element of its `Document`[p127]**

Return the `Document`[p127]'s viewport.

↪ **If *focus target* is a navigable[p952]**

Return the navigable[p952]'s active document[p952].

↪ **If *focus target* is a navigable container[p955] with a non-null content navigable[p955]**

Return the navigable container[p955]'s content navigable[p955]'s active document[p952].

↪ **If *focus target* is a shadow host whose shadow root's delegates focus is true**

1. Let *focusedElement* be the currently focused area of a top-level traversable[p817]'s DOM anchor[p815].
2. If *focus target* is a shadow-including inclusive ancestor of *focusedElement*, then return *focusedElement*.
3. Return the focus delegate[p822] for *focus target* given *focus trigger*.

Note

For sequential focusability[p817], the handling of shadow hosts and delegates focus is done when constructing the sequential focus navigation order[p825]. That is, the focusing steps[p822] will never be called on such shadow hosts as part of sequential focus navigation.

↪ **Otherwise**

Return null.

The **focus delegate** for a *focusTarget*, given an optional string *focusTrigger* (default "`other`"), is given by the following steps:

1. If *focusTarget* is a shadow host and its shadow root's delegates focus is false, then return null.
2. Let *whereToLook* be *focusTarget*.
3. If *whereToLook* is a shadow host, then set *whereToLook* to *whereToLook*'s shadow root.
4. Let *autofocusDelegate* be the autofocus delegate[p822] for *whereToLook* given *focusTrigger*.
5. If *autofocusDelegate* is not null, then return *autofocusDelegate*.
6. For each *descendant* of *whereToLook*'s descendants, in tree order:
    1. Let *focusableArea* be null.
    2. If *focusTarget* is a `dialog`[p633] element and *descendant* is sequentially focusable[p817], then set *focusableArea* to *descendant*.
    3. Otherwise, if *focusTarget* is not a `dialog`[p633] and *descendant* is a focusable area[p815], set *focusableArea* to *descendant*.
    4. Otherwise, set *focusableArea* to the result of getting the focusable area[p821] for *descendant* given *focusTrigger*.

        Note

        This step can end up recursing, i.e., the get the focusable area[p821] steps might return the focus delegate[p822] of descendant.

    5. If *focusableArea* is not null, then return *focusableArea*.

    Note

    It's important that we are not *looking at the shadow-including descendants here, but instead only at the descendants. Shadow hosts are instead handled by the recursive case mentioned above.*

7. Return null.

Note

The above algorithm essentially returns the first suitable focusable area[p815] where the path between its DOM anchor[p815] and focusTarget *delegates focus at any shadow tree boundaries.*

The **autofocus delegate** for a *focus target* given a *focus trigger* is given by the following steps:

1. For each descendant *descendant* of *focus target*, in tree order:
    1. If *descendant* does not have an `autofocus`[p828] content attribute, then continue.
    2. Let *focusable area* be *descendant*, if *descendant* is a focusable area[p815]; otherwise let *focusable area* be the result of getting the focusable area[p821] for *descendant* given *focus trigger*.
    3. If *focusable area* is null, then continue.
    4. If *focusable area* is not click focusable[p817] and *focus trigger* is "`click`", then continue.
    5. Return *focusable area*.
2. Return null.

The **focusing steps** for an object *new focus target* that is either a focusable area[p815], or an element that is not a focusable area[p815], or

a navigable[p952], are as follows. They can optionally be run with a *fallback target* and a string *focus trigger*.

1. If *new focus target* is not a focusable area[p815], then set *new focus target* to the result of getting the focusable area[p821] for *new focus target*, given *focus trigger* if it was passed.
2. If *new focus target* is null, then:
    1. If no *fallback target* was specified, then return.
    2. Otherwise, set *new focus target* to the *fallback target*.
3. If *new focus target* is a navigable container[p955] with non-null content navigable[p955], then set *new focus target* to the content navigable[p955]'s active document[p952].
4. If *new focus target* is a focusable area[p815] and its DOM anchor[p815] is inert[p808], then return.
5. If *new focus target* is the currently focused area of a top-level traversable[p817], then return.
6. Let *old chain* be the current focus chain of the top-level traversable[p817] in which *new focus target* finds itself.
7. Let *new chain* be the focus chain[p817] of *new focus target*.
8. Run the focus update steps[p823] with *old chain*, *new chain*, and *new focus target* respectively.

User agents must immediately[p43] run the focusing steps[p822] for a focusable area[p815] or navigable[p952] *candidate* whenever the user attempts to move the focus to *candidate*.

The **unfocusing steps** for an object *old focus target* that is either a focusable area[p815] or an element that is not a focusable area[p815] are as follows:

1. If *old focus target* is a shadow host whose shadow root's delegates focus is true, and *old focus target*'s shadow root is a shadow-including inclusive ancestor of the currently focused area of a top-level traversable[p817]'s DOM anchor[p815], then set *old focus target* to that currently focused area of a top-level traversable[p817].
2. If *old focus target* is inert[p808], then return.
3. If *old focus target* is an `area`[p463] element and one of its shapes is the currently focused area of a top-level traversable[p817], or, if *old focus target* is an element with one or more scrollable regions, and one of them is the currently focused area of a top-level traversable[p817], then let *old focus target* be that currently focused area of a top-level traversable[p817].
4. Let *old chain* be the current focus chain of the top-level traversable[p817] in which *old focus target* finds itself.
5. If *old focus target* is not one of the entries in *old chain*, then return.
6. If *old focus target* is not a focusable area[p815], then return.
7. Let *topDocument* be *old chain*'s last entry.
8. If *topDocument*'s node navigable[p953] has system focus[p815], then run the focusing steps[p822] for *topDocument*'s viewport.

   Otherwise, apply any relevant platform-specific conventions for removing system focus[p815] from *topDocument*'s node navigable[p953], and run the focus update steps[p823] given *old chain*, an empty list, and null.

Note

The unfocusing steps[p823] do not always result in the focus changing, even when applied to the currently focused area of a top-level traversable[p817]. For example, if the currently focused area of a top-level traversable[p817] is a viewport, then it will usually keep its focus regardless until another focusable area[p815] is explicitly focused with the focusing steps[p822].

The **focus update steps**, given an *old chain*, a *new chain*, and a *new focus target* respectively, are as follows:

1. If the last entry in *old chain* and the last entry in *new chain* are the same, pop the last entry from *old chain* and the last entry from *new chain* and redo this step.
2. For each entry *entry* in *old chain*, in order, run these substeps:
    1. If *entry* is an `input`[p512] element, and the `change`[p1406] event applies[p515] to the element, and the element does not have a defined activation behavior, and the user has changed the element's value[p587] or its list of selected files[p535]

while the control was focused without committing that change (such that it is different to what it was when the control was first focused), then fire an event named `change`[p1406] at the element, with the `bubbles` attribute initialized to true.

2. If *entry* is an element, let *blur event target* be *entry*.

   If *entry* is a `Document`[p127] object, let *blur event target* be that `Document`[p127] object's relevant global object[p1039].

   Otherwise, let *blur event target* be null.

3. If *entry* is the last entry in *old chain*, and *entry* is an `Element`, and the last entry in *new chain* is also an `Element`, then let *related blur target* be the last entry in *new chain*. Otherwise, let *related blur target* be null.

4. If *blur event target* is not null, fire a focus event[p824] named `blur`[p1406] at *blur event target*, with *related blur target* as the related target.

   Note

   In some cases, e.g., if entry *is an* `area`[p463] *element's shape, a scrollable region, or a viewport, no event is fired.*

3. Apply any relevant platform-specific conventions for focusing *new focus target*. (For example, some platforms select the contents of a text control when that control is focused.)

4. For each entry *entry* in *new chain*, in reverse order, run these substeps:

   1. If *entry* is a focusable area[p815], and the focused area of the document[p817] is not *entry*:

      1. Set *document*'s relevant global object[p1039]'s navigation API[p922]'s focus changed during ongoing navigation[p934] to true.

      2. Designate *entry* as the focused area of the document[p817].

   2. If *entry* is an element, let *focus event target* be *entry*.

      If *entry* is a `Document`[p127] object, let *focus event target* be that `Document`[p127] object's relevant global object[p1039].

      Otherwise, let *focus event target* be null.

   3. If *entry* is the last entry in *new chain*, and *entry* is an `Element`, and the last entry in *old chain* is also an `Element`, then let *related focus target* be the last entry in *old chain*. Otherwise, let *related focus target* be null.

   4. If *focus event target* is not null, fire a focus event[p824] named `focus`[p1406] at *focus event target*, with *related focus target* as the related target.

      Note

      In some cases, e.g. if entry *is an* `area`[p463] *element's shape, a scrollable region, or a viewport, no event is fired.*

To **fire a focus event** named *e* at an element *t* with a given related target *r*, fire an event named *e* at *t*, using `FocusEvent`, with the `relatedTarget` attribute initialized to *r*, the `view` attribute initialized to *t*'s node document's relevant global object[p1039], and the composed flag set.

When a key event is to be routed in a top-level traversable[p953], the user agent must run the following steps:

1. Let *target area* be the currently focused area of the top-level traversable[p817].

2. Assert: *target area* is not null, since key events are only routed to top-level traversables[p953] that have system focus[p815]. Therefore, *target area* is a focusable area[p815].

3. Let *target node* be *target area*'s DOM anchor[p815].

4. If *target node* is a `Document`[p127] that has a body element[p133], then let *target node* be the body element[p133] of that `Document`[p127].

   Otherwise, if *target node* is a `Document`[p127] object that has a non-null document element, then let *target node* be that document element.

5. If *target node* is not inert[p808], then:

1. Let *canHandle* be the result of dispatching the key event at *target node*.
2. If *canHandle* is true, then let *target area* handle the key event. This might include firing a `click` event[p1094] at *target node*.

The **has focus steps**, given a `Document`[p127] object *target*, are as follows:

1. If *target*'s node navigable[p953]'s top-level traversable[p954] does not have system focus[p815], then return false.
2. Let *candidate* be *target*'s node navigable[p953]'s top-level traversable[p954]'s active document[p961].
3. While true:
    1. If *candidate* is *target*, then return true.
    2. If the focused area[p817] of *candidate* is a navigable container[p955] with a non-null content navigable[p955], then set *candidate* to the active document[p952] of that navigable container[p955]'s content navigable[p955].
    3. Otherwise, return false.

6.6.5 Sequential focus navigation §[p825]

Each `Document`[p127] has a **sequential focus navigation order**, which orders some or all of the focusable areas[p815] in the `Document`[p127] relative to each other. Its contents and ordering are given by the flattened tabindex-ordered focus navigation scope[p819] of the `Document`[p127].

Note

Per the rules defining the flattened tabindex-ordered focus navigation scope[p819], the ordering is not necessarily related to the tree order of the `Document`[p127].

If a focusable area[p815] is omitted from the sequential focus navigation order[p825] of its `Document`[p127], then it is unreachable via sequential focus navigation[p825].

There can also be a **sequential focus navigation starting point**. It is initially unset. The user agent may set it when the user indicates that it should be moved.

Example

For example, the user agent could set it to the position of the user's click if the user clicks on the document contents.

Note

User agents are required to set the sequential focus navigation starting point[p825] to the target element[p1012] when navigating to a fragment[p984].

When the user requests that focus move from the currently focused area of a top-level traversable[p817] to the next or previous focusable area[p815] (e.g. as the default action of pressing the `tab` key), or when the user requests that focus sequentially move to a top-level traversable[p953] in the first place (e.g. from the browser's location bar), the user agent must use the following algorithm:

1. Let *starting point* be the currently focused area of a top-level traversable[p817], if the user requested to move focus sequentially from there, or else the top-level traversable[p953] itself, if the user instead requested to move focus from outside the top-level traversable[p953].
2. If there is a sequential focus navigation starting point[p825] defined and it is inside *starting point*, then let *starting point* be the sequential focus navigation starting point[p825] instead.
3. Let *direction* be *forward* if the user requested the *next* control, and *backward* if the user requested the previous control.

    Note

    Typically, pressing `tab` requests the next control, and pressing `shift + tab` requests the previous control.

4. *Loop*: Let *selection mechanism* be *sequential* if the *starting point* is a navigable[p952] or if *starting point* is in its `Document`[p127]'s

sequential focus navigation order[p825].

Otherwise, *starting point* is not in its `Document`[p127]'s sequential focus navigation order[p825]; let *selection mechanism* be *DOM*.

5. Let *candidate* be the result of running the sequential navigation search algorithm[p826] with *starting point*, *direction*, and *selection mechanism* as the arguments.

6. If *candidate* is not null, then run the focusing steps[p822] for *candidate* and return.

7. Otherwise, unset the sequential focus navigation starting point[p825].

8. If *starting point* is a top-level traversable[p953], or a focusable area[p815] in the top-level traversable[p953], the user agent should transfer focus to its own controls appropriately (if any), honouring *direction*, and then return.

   Example

   For example, if *direction* is *backward*, then the last sequentially focusable[p817] control before the browser's rendering area would be the control to focus.

   If the user agent has no sequentially focusable[p817] controls — a kiosk-mode browser, for instance — then the user agent may instead restart these steps with the *starting point* being the top-level traversable[p953] itself.

9. Otherwise, *starting point* is a focusable area[p815] in a child navigable[p955]. Set *starting point* to that child navigable[p955]'s parent[p952] and return to the step labeled *loop*.

The **sequential navigation search algorithm** consists of the following steps. This algorithm takes three arguments: *starting point*, *direction*, and *selection mechanism*.

1. Pick the appropriate cell from the following table, and follow the instructions in that cell.

   The appropriate cell is the one that is from the column whose header describes *direction* and from the first row whose header describes *starting point* and *selection mechanism*.

	direction* is *forward	***direction* is *backward***
***starting point* is a navigable[p952]**	Let *candidate* be the first suitable sequentially focusable area[p826] in *starting point*'s active document[p952], if any; or else null	Let *candidate* be the last suitable sequentially focusable area[p826] in *starting point*'s active document[p952], if any; or else null
selection mechanism* is *DOM	Let *candidate* be the first suitable sequentially focusable area[p826] in the home document[p826] following *starting point*, if any; or else null	Let *candidate* be the last suitable sequentially focusable area[p826] in the home document[p826] preceding *starting point*, if any; or else null
selection mechanism* is *sequential	Let *candidate* be the first suitable sequentially focusable area[p826] in the home sequential focus navigation order[p826] following *starting point*, if any; or else null	Let *candidate* be the last suitable sequentially focusable area[p826] in the home sequential focus navigation order[p826] preceding *starting point*, if any; or else null

   A **suitable sequentially focusable area** is a focusable area[p815] whose DOM anchor[p815] is not inert[p808] and is sequentially focusable[p817].

   The **home document** is the `Document`[p127] to which *starting point* belongs.

   The **home sequential focus navigation order** is the sequential focus navigation order[p825] to which *starting point* belongs.

   Note

   The home sequential focus navigation order[p826] is the home document[p826]'s sequential focus navigation order[p825], but is only used when the starting point *is in that sequential focus navigation order[p825] (when it's not,* selection mechanism *will be* DOM*).*

2. If *candidate* is a navigable container[p955] with a non-null content navigable[p955], then let *new candidate* be the result of running the sequential navigation search algorithm[p826] with *candidate*'s content navigable[p955] as the first argument, *direction* as the second, and *sequential* as the third.

   If *new candidate* is null, then let *starting point* be *candidate*, and return to the top of this algorithm. Otherwise, let *candidate* be *new candidate*.

3. Return *candidate*.

6.6.6 Focus management APIs §[p827]

```
IDL
dictionary FocusOptions {
  boolean preventScroll = false;
  boolean focusVisible;
};
```

For web developers (non-normative)

***documentOrShadowRoot*.activeElement**[p827]

Returns the deepest element in the document through which or to which key events are being routed. This is, roughly speaking, the focused element in the document.

For the purposes of this API, when a child navigable[p955] is focused, its container[p955] is focused[p816] within its parent[p952]'s active document[p952]. For example, if the user moves the focus to a text control in an `iframe`[p383], the `iframe`[p383] is the element returned by the `activeElement`[p827] API in the `iframe`[p383]'s node document.

Similarly, when the focused element is in a different node tree than *documentOrShadowRoot*, the element returned will be the host that's located in the same node tree as *documentOrShadowRoot* if *documentOrShadowRoot* is a shadow-including inclusive ancestor of the focused element, and null if not.

***document*.hasFocus**[p828]**()**

Returns true if key events are being routed through or to the document; otherwise, returns false. Roughly speaking, this corresponds to the document, or a document nested inside this one, being focused.

***window*.focus**[p828]**()**

Moves the focus to the window's navigable[p894], if any.

***element*.focus**[p828]**([{ preventScroll**[p828]**: true }])**

Moves the focus to the element.

If the element is a navigable container[p955], moves the focus to its content navigable[p955] instead.

By default, this method also scrolls the element into view. Providing the `preventScroll`[p828] option and setting it to true prevents this behavior.

***element*.blur**[p828]**()**

Moves the focus to the viewport. Use of this method is discouraged; if you want to focus the viewport, call the `focus()`[p828] method on the `Document`[p127]'s document element.

Do not use this method to hide the focus ring if you find the focus ring unsightly. Instead, use the `:focus-visible` pseudo-class to override the 'outline' property, and provide a different way to show what element is focused. Be aware that if an alternative focusing style isn't made available, the page will be significantly less usable for people who primarily navigate pages using a keyboard, or those with reduced vision who use focus outlines to help them navigate the page.

Example

For example, to hide the outline from `textarea`[p570] elements and instead use a yellow background to indicate focus, you could use:

```
CSS
textarea:focus-visible { outline: none; background: yellow; color: black; }
```

The **`activeElement`** attribute's getter must run these steps:

1. Let *candidate* be the DOM anchor[p815] of the focused area[p817] of this `DocumentOrShadowRoot`[p128]'s node document.
2. Set *candidate* to the result of retargeting *candidate* against this `DocumentOrShadowRoot`[p128].
3. If *candidate*'s root is not this `DocumentOrShadowRoot`[p128], then return null.
4. If *candidate* is not a `Document`[p127] object, then return *candidate*.
5. If *candidate* has a body element[p133], then return that body element[p133].
6. If *candidate*'s document element is non-null, then return that document element.
7. Return null.

The **hasFocus()** method on the Document[p127] object, when invoked, must return the result of running the has focus steps[p825] with the Document[p127] object as the argument.

The **focus()** method, when invoked, must run these steps:

1. Let *current* be this Window[p892] object's navigable[p894].
2. If *current* is null, then return.
3. Run the focusing steps[p822] with *current*.
4. If *current* is a top-level traversable[p953], user agents are encouraged to trigger some sort of notification to indicate to the user that the page is attempting to gain focus.

The **blur()** method steps are to do nothing.

✔ MDN

Note

Historically, the focus()[p828] and blur()[p828] methods actually affected the system-level focus of the system widget (e.g., tab or window) that contained the navigable[p952], but hostile sites widely abuse this behavior to the user's detriment.

The **focus(*options*)** method on elements, when invoked, must run the following steps:

1. If the element is marked as *locked for focus*[p828], then return.
2. Mark the element as **locked for focus**.
3. Run the focusing steps[p822] for the element.
4. If the value of the **focusVisible** dictionary member of *options* is true, or is not present but in an implementation-defined way the user agent determines it would be best to do so, then indicate focus.
5. If the value of the **preventScroll** dictionary member of *options* is false, then scroll the element into view with scroll behavior "auto", block flow direction position set to an implementation-defined value, and inline base direction position set to an implementation-defined value.
6. Unmark the element as *locked for focus*[p828].

The **blur()** method, when invoked, should run the unfocusing steps[p823] for the element on which the method was called. User agents may selectively or uniformly ignore calls to this method for usability reasons.

Example

For example, if the blur()[p828] method is unwisely being used to remove the focus ring for aesthetics reasons, the page would become unusable by keyboard users. Ignoring calls to this method would thus allow keyboard users to interact with the page.

6.6.7 The autofocus[p828] attribute §[p828]

The **autofocus** content attribute allows the author to indicate that an element is to be focused as soon as the page is loaded, allowing the user to just start typing without having to manually focus the main element.

When the autofocus[p828] attribute is specified on an element inside dialog[p633] elements or HTML elements[p45] whose popover[p857] attribute is set, then it will be focused when the dialog or popover becomes shown.

The autofocus[p828] attribute is a boolean attribute[p72].

To find the **nearest ancestor autofocus scoping root element** given an Element *element*:

1. If *element* is a dialog[p633] element, then return *element*.
2. If *element*'s popover[p857] attribute is not in the no popover state[p859], then return *element*.
3. Let *ancestor* be *element*.
4. While *ancestor* has a parent element:

    1. Set *ancestor* to *ancestor*'s parent element.
    2. If *ancestor* is a `dialog`[p633] element, then return *ancestor*.
    3. If *ancestor*'s `popover`[p857] attribute is not in the no popover state[p859], then return *ancestor*.
5. Return *ancestor*.

There must not be two elements with the same nearest ancestor autofocus scoping root element[p828] that both have the `autofocus`[p828] attribute specified.

Each `Document`[p127] has an **autofocus candidates** list, initially empty.

Each `Document`[p127] has an **autofocus processed flag** boolean, initially false.

When an element with the `autofocus`[p828] attribute specified is inserted into a document[p46], run the following steps:

1. If the user has indicated (for example, by starting to type in a form control) that they do not wish focus to be changed, then optionally return.
2. Let *target* be the element's node document.
3. If *target* is not fully active[p966], then return.
4. If *target*'s active sandboxing flag set[p887] has the sandboxed automatic features browsing context flag[p885], then return.
5. For each *ancestorNavigable* of *target*'s ancestor navigables[p957]: if *ancestorNavigable*'s active document[p952]'s origin is not same origin[p870] with *target*'s origin, then return.
6. Let *topDocument* be *target*'s node navigable[p953]'s top-level traversable[p954]'s active document[p952].
7. If *topDocument*'s autofocus processed flag[p829] is false, then remove the element from *topDocument*'s autofocus candidates[p829], and append the element to *topDocument*'s autofocus candidates[p829].

Note

We do not check if an element is a focusable area[p815] before storing it in the autofocus candidates[p829] list, because even if it is not a focusable area when it is inserted, it could become one by the time flush autofocus candidates[p829] sees it.

To **flush autofocus candidates** for a document *topDocument*, run these steps:

1. If *topDocument*'s autofocus processed flag[p829] is true, then return.
2. Let *candidates* be *topDocument*'s autofocus candidates[p829].
3. If *candidates* is empty, then return.
4. If *topDocument*'s focused area[p817] is not *topDocument* itself, or *topDocument* has non-null target element[p1012], then:
    1. Empty *candidates*.
    2. Set *topDocument*'s autofocus processed flag[p829] to true.
    3. Return.
5. While *candidates* is not empty:
    1. Let *element* be *candidates*[0].
    2. Let *doc* be *element*'s node document.
    3. If *doc* is not fully active[p966], then remove *element* from *candidates*, and continue.
    4. If *doc*'s node navigable[p953]'s top-level traversable[p954] is not the same as *topDocument*'s node navigable[p953], then remove *element* from *candidates*, and continue.
    5. If *doc*'s script-blocking style sheet set[p199] is not empty, then return.

Note

In this case, element is the currently-best candidate, but doc is not ready for autofocusing. We'll try again next time flush autofocus candidates[p829] is called.

6. Remove *element* from *candidates*.
7. Let *inclusiveAncestorDocuments* be a list consisting of the active document[p952] of *doc*'s inclusive ancestor navigables[p957].
8. If any `Document`[p127] in *inclusiveAncestorDocuments* has non-null target element[p1012], then continue.
9. Let *target* be *element*.
10. If *target* is not a focusable area[p815], then set *target* to the result of getting the focusable area[p821] for *target*.

    Note

    Autofocus candidates[p829] can contain elements which are not focusable areas[p815]. In addition to the special cases handled in the get the focusable area[p821] algorithm, this can happen because a non-focusable area[p815] element with an `autofocus`[p828] attribute was inserted into a document[p46] and it never became focusable, or because the element was focusable but its status changed while it was stored in autofocus candidates[p829].

11. If *target* is not null, then:
    1. Empty *candidates*.
    2. Set *topDocument*'s autofocus processed flag[p829] to true.
    3. Run the focusing steps[p822] for *target*.

Note

This handles the automatic focusing during document load. The `show()`[p635] and `showModal()`[p636] methods of `dialog`[p633] elements also processes the `autofocus`[p828] attribute.

Note

Focusing the element does not imply that the user agent has to focus the browser window if it has lost focus.

The **`autofocus`** IDL attribute must reflect[p101] the content attribute of the same name.

Example

In the following snippet, the text control would be focused when the document was loaded.

```
<input maxlength="256" name="q" value="" autofocus>
<input type="submit" value="Search">
```

Example

The `autofocus`[p828] attribute applies to all elements, not just to form controls. This allows examples such as the following:

```
<div contenteditable autofocus>Edit <strong>me!</strong><div>
```

6.7 Assigning keyboard shortcuts §[p830]

6.7.1 Introduction §[p830]

This section is non-normative.

Each element that can be activated or focused can be assigned a single key combination to activate it, using the `accesskey`[p831] attribute.

The exact shortcut is determined by the user agent, based on information about the user's keyboard, what keyboard shortcuts already exist on the platform, and what other shortcuts have been specified on the page, using the information provided in the accesskey[p831] attribute as a guide.

In order to ensure that a relevant keyboard shortcut is available on a wide variety of input devices, the author can provide a number of alternatives in the accesskey[p831] attribute.

Each alternative consists of a single character, such as a letter or digit.

User agents can provide users with a list of the keyboard shortcuts, but authors are encouraged to do so also. The accessKeyLabel[p833] IDL attribute returns a string representing the actual key combination assigned by the user agent.

Example

In this example, an author has provided a button that can be invoked using a shortcut key. To support full keyboards, the author has provided "C" as a possible key. To support devices equipped only with numeric keypads, the author has provided "1" as another possible key.

```
<input type=button value=Collect onclick="collect()"
       accesskey="C 1" id=c>
```

Example

To tell the user what the shortcut key is, the author has this script here opted to explicitly add the key combination to the button's label:

```
function addShortcutKeyLabel(button) {
  if (button.accessKeyLabel != '')
    button.value += ' (' + button.accessKeyLabel + ')';
}
addShortcutKeyLabel(document.getElementById('c'));
```

Browsers on different platforms will show different labels, even for the same key combination, based on the convention prevalent on that platform. For example, if the key combination is the Control key, the Shift key, and the letter C, a Windows browser might display "`Ctrl+Shift+C`", whereas a Mac browser might display "`^⇧C`", while an Emacs browser might just display "`C-C`". Similarly, if the key combination is the Alt key and the Escape key, Windows might use "`Alt+Esc`", Mac might use "`⌥⎋`", and an Emacs browser might use "`M-ESC`" or "`ESC ESC`".

In general, therefore, it is unwise to attempt to parse the value returned from the accessKeyLabel[p833] IDL attribute.

✔ MDN

6.7.2 The accesskey attribute §[p831]

All HTML elements[p45] may have the accesskey[p831] content attribute set. The accesskey[p831] attribute's value is used by the user agent as a guide for creating a keyboard shortcut that activates or focuses the element.

If specified, the value must be an ordered set of unique space-separated tokens[p93] none of which are identical to another token and each of which must be exactly one code point in length.

Example

In the following example, a variety of links are given with access keys so that keyboard users familiar with the site can more quickly navigate to the relevant pages:

```
<nav>
 <p>
  <a title="Consortium Activities" accesskey="A" href="/Consortium/activities">Activities</a> |
  <a title="Technical Reports and Recommendations" accesskey="T" href="/TR/">Technical Reports</a>
|
  <a title="Alphabetical Site Index" accesskey="S" href="/Consortium/siteindex">Site Index</a> |
  <a title="About This Site" accesskey="B" href="/Consortium/">About Consortium</a> |
```

```
  <a title="Contact Consortium" accesskey="C" href="/Consortium/contact">Contact</a>
 </p>
</nav>
```

Example

In the following example, the search field is given two possible access keys, "s" and "0" (in that order). A user agent on a device with a full keyboard might pick `Ctrl + Alt + S` as the shortcut key, while a user agent on a small device with just a numeric keypad might pick just the plain unadorned key `0`:

```
<form action="/search">
 <label>Search: <input type="search" name="q" accesskey="s 0"></label>
 <input type="submit">
</form>
```

Example

In the following example, a button has possible access keys described. A script then tries to update the button's label to advertise the key combination the user agent selected.

```
<input type=submit accesskey="N @ 1" value="Compose">
...
<script>
 function labelButton(button) {
   if (button.accessKeyLabel)
     button.value += ' (' + button.accessKeyLabel + ')';
 }
 var inputs = document.getElementsByTagName('input');
 for (var i = 0; i < inputs.length; i += 1) {
   if (inputs[i].type == "submit")
     labelButton(inputs[i]);
 }
</script>
```

On one user agent, the button's label might become "`Compose (⌘N)`". On another, it might become "`Compose (Alt+⇧+1)`". If the user agent doesn't assign a key, it will be just "`Compose`". The exact string depends on what the assigned access key[p832] is, and on how the user agent represents that key combination.

6.7.3 Processing model §[p832]

An element's **assigned access key** is a key combination derived from the element's accesskey[p831] content attribute. Initially, an element must not have an assigned access key[p832].

Whenever an element's accesskey[p831] attribute is set, changed, or removed, the user agent must update the element's assigned access key[p832] by running the following steps:

1. If the element has no accesskey[p831] attribute, then skip to the *fallback* step below.
2. Otherwise, split the attribute's value on ASCII whitespace, and let *keys* be the resulting tokens.
3. For each value in *keys* in turn, in the order the tokens appeared in the attribute's value, run the following substeps:
    1. If the value is not a string exactly one code point in length, then skip the remainder of these steps for this value.
    2. If the value does not correspond to a key on the system's keyboard, then skip the remainder of these steps for this value.

3. If the user agent can find a mix of zero or more modifier keys that, combined with the key that corresponds to the value given in the attribute, can be used as the access key, then the user agent may assign that combination of keys as the element's assigned access key[p832] and return.

4. *Fallback*: Optionally, the user agent may assign a key combination of its choosing as the element's assigned access key[p832] and then return.

5. If this step is reached, the element has no assigned access key[p832].

Once a user agent has selected and assigned an access key for an element, the user agent should not change the element's assigned access key[p832] unless the `accesskey`[p831] content attribute is changed or the element is moved to another `Document`[p127].

When the user presses the key combination corresponding to the assigned access key[p832] for an element, if the element defines a command[p630], the command's Hidden State[p631] facet is false (visible), the command's Disabled State[p631] facet is also false (enabled), the element is in a document that has a non-null browsing context[p961], and neither the element nor any of its ancestors has a `hidden`[p805] attribute specified, then the user agent must trigger the Action[p631] of the command.

Note

User agents might expose[p631] elements that have an `accesskey`[p831] attribute in other ways as well, e.g. in a menu displayed in response to a specific key combination.

The **`accessKey`** IDL attribute must reflect[p101] the `accesskey`[p831] content attribute.

The **`accessKeyLabel`** IDL attribute must return a string that represents the element's assigned access key[p832], if any. If the element does not have one, then the IDL attribute must return the empty string.

6.8 Editing §[p833]

6.8.1 Making document regions editable: The `contenteditable`[p833] content attribute §[p833]

IDL

```
interface mixin ElementContentEditable {
  [CEReactions] attribute DOMString contentEditable;
  [CEReactions] attribute DOMString enterKeyHint;
  readonly attribute boolean isContentEditable;
  [CEReactions] attribute DOMString inputMode;
};
```

The **`contenteditable`** content attribute is an enumerated attribute[p73] whose keywords are the empty string, `true`, `plaintext-only` and `false`. The empty string and the `true` keyword map to the *true* state. The `plaintext-only` keyword maps to the *plaintext-only* state. The `false` keyword maps to the *false* state. In addition, there is a fourth state, the *inherit* state, which is the *missing value default*[p73] and the *invalid value default*[p73].

The *true* state indicates that the element is editable. The *plaintext-only* state indicates that only the element's raw text content is editable, but rich text formatting is disabled. The *inherit* state indicates that the element is the same kind of editable (or not editable) as the parent element. The *false* state indicates that the element is not editable.

Example

For example, consider a page that has a `form`[p505] and a `textarea`[p570] to publish a new article, where the user is expected to write the article using HTML:

```
<form method=POST>
 <fieldset>
  <legend>New article</legend>
  <textarea name=article>&lt;p>Hello world.&lt;/p></textarea>
 </fieldset>
 <p><button>Publish</button></p>
</form>
```

When scripting is enabled, the textarea[p570] element could be replaced with a rich text control instead, using the contenteditable[p833] attribute:

```
<form method=POST>
 <fieldset>
  <legend>New article</legend>
  <textarea id=textarea name=article>&lt;p>Hello world.&lt;/p></textarea>
  <div id=div style="white-space: pre-wrap" hidden><p>Hello world.</p></div>
  <script>
   let textarea = document.getElementById("textarea");
   let div = document.getElementById("div");
   textarea.hidden = true;
   div.hidden = false;
   div.contentEditable = "true";
   div.oninput = (e) => {
     textarea.value = div.innerHTML;
   };
  </script>
 </fieldset>
 <p><button>Publish</button></p>
</form>
```

Features to enable, e.g., inserting links, can be implemented using the document.execCommand() API, or using Selection APIs and other DOM APIs. [EXECCOMMAND][p1413] [SELECTION][p1417] [DOM][p1412]

Example

The contenteditable[p833] attribute can also be used to great effect:

```
<!doctype html>
<html lang=en>
<title>Live CSS editing!</title>
<style style=white-space:pre contenteditable>
html { margin:.2em; font-size:2em; color:lime; background:purple }
head, title, style { display:block }
body { display:none }
</style>
```

For web developers (non-normative)

***element*.contentEditable**[p834] **[= *value*]**

Returns "true", "plaintext-only", "false", or "inherit", based on the state of the contenteditable[p833] attribute.

Can be set, to change that state.

Throws a "SyntaxError" DOMException if the new value isn't one of those strings.

***element*.isContentEditable**[p834]

Returns true if the element is editable; otherwise, returns false.

The **contentEditable** IDL attribute, on getting, must return the string "true" if the content attribute is set to the true state, "plaintext-only" if the content attribute is set to the plaintext-only state, "false" if the content attribute is set to the false state, and "inherit" otherwise. On setting, if the new value is an ASCII case-insensitive match for the string "inherit" then the content attribute must be removed, if the new value is an ASCII case-insensitive match for the string "true" then the content attribute must be set to the string "true", if the new value is an ASCII case-insensitive match for the string "plaintext-only" then the content attribute must be set to the string "plaintext-only", if the new value is an ASCII case-insensitive match for the string "false" then the content attribute must be set to the string "false", and otherwise the attribute setter must throw a "SyntaxError" DOMException.

The **isContentEditable** IDL attribute, on getting, must return true if the element is either an editing host[p835] or editable, and false otherwise.

6.8.2 Making entire documents editable: the designMode[p835] getter and setter §[p835]

For web developers (non-normative)

***document*.designMode[p835] [= *value*]**

Returns "on" if the document is editable, and "off" if it isn't.

Can be set, to change the document's current state. This focuses the document and resets the selection in that document.

Document[p127] objects have an associated **design mode enabled**, which is a boolean. It is initially false.

The **designMode** getter steps are to return "on" if this's design mode enabled[p835] is true; otherwise "off".

The designMode[p835] setter steps are:

1. Let *value* be the given value, converted to ASCII lowercase.
2. If *value* is "on" and this's design mode enabled[p835] is false, then:
    1. Set this's design mode enabled[p835] to true.
    2. Reset this's active range's start and end boundary points to be at the start of this.
    3. Run the focusing steps[p822] for this's document element, if non-null.
3. If *value* is "off", then set this's design mode enabled[p835] to false.

6.8.3 Best practices for in-page editors §[p835]

Authors are encouraged to set the 'white-space' property on editing hosts[p835] and on markup that was originally created through these editing mechanisms to the value 'pre-wrap'. Default HTML whitespace handling is not well suited to WYSIWYG editing, and line wrapping will not work correctly in some corner cases if 'white-space' is left at its default value.

Example

As an example of problems that occur if the default 'normal' value is used instead, consider the case of the user typing "yellow␣␣ball", with two spaces (here represented by "␣") between the words. With the editing rules in place for the default value of 'white-space' ('normal'), the resulting markup will either consist of "yellow   ball" or "yellow   ball"; i.e., there will be a non-breaking space between the two words in addition to the regular space. This is necessary because the 'normal' value for 'white-space' requires adjacent regular spaces to be collapsed together.

In the former case, "yellow␣" might wrap to the next line ("␣" being used here to represent a non-breaking space) even though "yellow" alone might fit at the end of the line; in the latter case, "␣ball", if wrapped to the start of the line, would have visible indentation from the non-breaking space.

When 'white-space' is set to 'pre-wrap', however, the editing rules will instead simply put two regular spaces between the words, and should the two words be split at the end of a line, the spaces would be neatly removed from the rendering.

6.8.4 Editing APIs §[p835]

An **editing host** is either an HTML element[p45] with its contenteditable[p833] attribute in the *true* state or *plaintext-only* state, or a child HTML element[p45] of a Document[p127] whose design mode enabled[p835] is true.

The definition of the terms **active range**, **editing host of**, and **editable**, the user interface requirements of elements that are editing hosts[p835] or editable, the **execCommand()**, **queryCommandEnabled()**, **queryCommandIndeterm()**, **queryCommandState()**, **queryCommandSupported()**, and **queryCommandValue()** methods, text selections, and the **delete the selection** algorithm are defined in *execCommand*. [EXECCOMMAND][p1413]

6.8.5 Spelling and grammar checking §[p836]

User agents can support the checking of spelling and grammar of editable text, either in form controls (such as the value of `textarea`[p570] elements), or in elements in an editing host[p835] (e.g. using `contenteditable`[p833]).

For each element, user agents must establish a **default behavior**, either through defaults or through preferences expressed by the user. There are three possible default behaviors for each element:

true-by-default

The element will be checked for spelling and grammar if its contents are editable and spellchecking is not explicitly disabled through the `spellcheck`[p836] attribute.

false-by-default

The element will never be checked for spelling and grammar unless spellchecking is explicitly enabled through the `spellcheck`[p836] attribute.

inherit-by-default

The element's default behavior is the same as its parent element's. Elements that have no parent element cannot have this as their default behavior.

The **`spellcheck`** attribute is an enumerated attribute[p73] whose keywords are the empty string, `true` and `false`. The empty string and the `true` keyword map to the *true* state. The `false` keyword maps to the *false* state. In addition, there is a third state, the *default* state, which is the *missing value default*[p73] and the *invalid value default*[p73].

Note

The true *state indicates that the element is to have its spelling and grammar checked. The* default *state indicates that the element is to act according to a default behavior, possibly based on the parent element's own* `spellcheck`[p836] *state, as defined below. The* false *state indicates that the element is not to be checked.*

For web developers (non-normative)

***element*.spellcheck**[p836] **[= *value*]**

Returns true if the element is to have its spelling and grammar checked; otherwise, returns false.

Can be set, to override the default and set the `spellcheck`[p836] content attribute.

The **`spellcheck`** IDL attribute, on getting, must return true if the element's `spellcheck`[p836] content attribute is in the *true* state, or if the element's `spellcheck`[p836] content attribute is in the *default* state and the element's default behavior[p836] is true-by-default[p836], or if the element's `spellcheck`[p836] content attribute is in the *default* state and the element's default behavior[p836] is inherit-by-default[p836] and the element's parent element's `spellcheck`[p836] IDL attribute would return true; otherwise, if none of those conditions applies, then the attribute must instead return false.

Note

The `spellcheck`[p836] *IDL attribute is not affected by user preferences that override the* `spellcheck`[p836] *content attribute, and therefore might not reflect the actual spellchecking state.*

On setting, if the new value is true, then the element's `spellcheck`[p836] content attribute must be set to the literal string "`true`", otherwise it must be set to the literal string "`false`".

User agents must only consider the following pieces of text as checkable for the purposes of this feature:

- The value[p587] of `input`[p512] elements whose `type`[p514] attributes are in the Text[p519], Search[p519], URL[p520], or Email[p521] states and that are *mutable*[p588] (i.e. that do not have the `readonly`[p542] attribute specified and that are not disabled[p592]).
- The value[p587] of `textarea`[p570] elements that do not have a `readonly`[p571] attribute and that are not disabled[p592].
- Text in `Text` nodes that are children of editing hosts[p835] or editable elements.
- Text in attributes of editable elements.

For text that is part of a `Text` node, the element with which the text is associated is the element that is the immediate parent of the

first character of the word, sentence, or other piece of text. For text in attributes, it is the attribute's element. For the values of input[p512] and textarea[p570] elements, it is the element itself.

To determine if a word, sentence, or other piece of text in an applicable element (as defined above) is to have spelling- and grammar-checking enabled, the UA must use the following algorithm:

1. If the user has disabled the checking for this text, then the checking is disabled.
2. Otherwise, if the user has forced the checking for this text to always be enabled, then the checking is enabled.
3. Otherwise, if the element with which the text is associated has a spellcheck[p836] content attribute, then: if that attribute is in the *true* state, then checking is enabled; otherwise, if that attribute is in the *false* state, then checking is disabled.
4. Otherwise, if there is an ancestor element with a spellcheck[p836] content attribute that is not in the *default* state, then: if the nearest such ancestor's spellcheck[p836] content attribute is in the *true* state, then checking is enabled; otherwise, checking is disabled.
5. Otherwise, if the element's default behavior[p836] is true-by-default[p836], then checking is enabled.
6. Otherwise, if the element's default behavior[p836] is false-by-default[p836], then checking is disabled.
7. Otherwise, if the element's parent element has *its* checking enabled, then checking is enabled.
8. Otherwise, checking is disabled.

If the checking is enabled for a word/sentence/text, the user agent should indicate spelling and grammar errors in that text. User agents should take into account the other semantics given in the document when suggesting spelling and grammar corrections. User agents may use the language of the element to determine what spelling and grammar rules to use, or may use the user's preferred language settings. UAs should use input[p512] element attributes such as pattern[p544] to ensure that the resulting value is valid, where possible.

If checking is disabled, the user agent should not indicate spelling or grammar errors for that text.

Example

The element with ID "a" in the following example would be the one used to determine if the word "Hello" is checked for spelling errors. In this example, it would not be.

```
<div contenteditable="true">
 <span spellcheck="false" id="a">Hell</span><em>o!</em>
</div>
```

The element with ID "b" in the following example would have checking enabled (the leading space character in the attribute's value on the input[p512] element causes the attribute to be ignored, so the ancestor's value is used instead, regardless of the default).

```
<p spellcheck="true">
 <label>Name: <input spellcheck=" false" id="b"></label>
</p>
```

Note

This specification does not define the user interface for spelling and grammar checkers. A user agent could offer on-demand checking, could perform continuous checking while the checking is enabled, or could use other interfaces.

6.8.6 Autocapitalization §[p837]

Some methods of entering text, for example virtual keyboards on mobile devices, and also voice input, often assist users by automatically capitalizing the first letter of sentences (when composing text in a language with this convention). A virtual keyboard that implements autocapitalization might automatically switch to showing uppercase letters (but allow the user to toggle it back to lowercase) when a letter that should be autocapitalized is about to be typed. Other types of input, for example voice input, may perform autocapitalization in a way that does not give users an option to intervene first. The autocapitalize[p838] attribute allows authors to control such behavior.

The autocapitalize[p838] attribute, as typically implemented, does not affect behavior when typing on a physical keyboard. (For this reason, as well as the ability for users to override the autocapitalization behavior in some cases or edit the text after initial input, the attribute must not be relied on for any sort of input validation.)

The autocapitalize[p838] attribute can be used on an editing host[p835] to control autocapitalization behavior for the hosted editable region, on an input[p512] or textarea[p570] element to control the behavior for inputting text into that element, or on a form[p505] element to control the default behavior for all autocapitalize-inheriting elements[p505] associated with the form[p505] element.

The autocapitalize[p838] attribute never causes autocapitalization to be enabled for input[p512] elements whose type[p514] attribute is in one of the URL[p520], Email[p521], or Password[p523] states. (This behavior is included in the used autocapitalization hint[p839] algorithm below.)

The autocapitalization processing model is based on selecting among five **autocapitalization hints**, defined as follows:

default

The user agent and input method should use make their own determination of whether or not to enable autocapitalization.

none

No autocapitalization should be applied (all letters should default to lowercase).

sentences

The first letter of each sentence should default to a capital letter; all other letters should default to lowercase.

words

The first letter of each word should default to a capital letter; all other letters should default to lowercase.

characters

All letters should default to uppercase.

The **autocapitalize** attribute is an enumerated attribute[p73] whose states are the possible autocapitalization hints[p838]. The autocapitalization hint[p838] specified by the attribute's state combines with other considerations to form the used autocapitalization hint[p839], which informs the behavior of the user agent. The keywords for this attribute and their state mappings are as follows:

Keyword	State
off	none[p838]
none	
on	sentences[p838]
sentences	
words	words[p838]
characters	characters[p838]

The *invalid value default*[p73] is the sentences[p838] state. The *missing value default*[p73] is the default[p838] state.

For web developers (non-normative)

***element*.autocapitalize[p838] [= *value*]**

Returns the current autocapitalization state for the element, or an empty string if it hasn't been set. Note that for input[p512] and textarea[p570] elements that inherit their state from a form[p505] element, this will return the autocapitalization state of the form[p505] element, but for an element in an editable region, this will not return the autocapitalization state of the editing host (unless this element is, in fact, the editing host[p835]).

Can be set, to set the autocapitalize[p838] content attribute (and thereby change the autocapitalization behavior for the element).

To compute the **own autocapitalization hint** of an element *element*, run the following steps:

1. If the autocapitalize[p838] content attribute is present on *element*, and its value is not the empty string, return the state of the attribute.
2. If *element* is an autocapitalize-inheriting element[p505] and has a non-null form owner[p588], return the own autocapitalization hint[p838] of *element*'s form owner[p588].
3. Return default[p838].

The **autocapitalize** getter steps are to:

1. Let *state* be the own autocapitalization hint[p838] of this.
2. If *state* is default[p838], then return the empty string.
3. If *state* is none[p838], then return "none[p838]".
4. If *state* is sentences[p838], then return "sentences[p838]".
5. Return the keyword value corresponding to *state*.

The autocapitalize[p838] setter steps are to set the autocapitalize[p838] content attribute to the given value.

User agents that support customizable autocapitalization behavior for a text input method and wish to allow web developers to control this functionality should, during text input into an element, compute the **used autocapitalization hint** for the element. This will be an autocapitalization hint[p838] that describes the recommended autocapitalization behavior for text input into the element.

User agents or input methods may choose to ignore or override the used autocapitalization hint[p839] in certain circumstances.

The used autocapitalization hint[p839] for an element *element* is computed using the following algorithm:

1. If *element* is an input[p512] element whose type[p514] attribute is in one of the URL[p520], Email[p521], or Password[p523] states, then return default[p838].
2. If *element* is an input[p512] element or a textarea[p570] element, then return *element*'s own autocapitalization hint[p838].
3. If *element* is an editing host[p835] or an editable element, then return the own autocapitalization hint[p838] of the editing host of *element*.
4. Assert: this step is never reached, since text input only occurs in elements that meet one of the above criteria.

6.8.7 Input modalities: the inputmode[p839] attribute §[p839]

User agents can support the inputmode[p839] attribute on form controls (such as the value of textarea[p570] elements), or in elements in an editing host[p835] (e.g., using contenteditable[p833]).

The **inputmode** content attribute is an enumerated attribute[p73] that specifies what kind of input mechanism would be most helpful for users entering content.

Keyword	Description
none	The user agent should not display a virtual keyboard. This keyword is useful for content that renders its own keyboard control.
text	The user agent should display a virtual keyboard capable of text input in the user's locale.
tel	The user agent should display a virtual keyboard capable of telephone number input. This should including keys for the digits 0 to 9, the "#" character, and the "*" character. In some locales, this can also include alphabetic mnemonic labels (e.g., in the US, the key labeled "2" is historically also labeled with the letters A, B, and C).
url	The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of URLs, such as that for the "/" and "." characters and for quick input of strings commonly found in domain names such as "www." or ".com".
email	The user agent should display a virtual keyboard capable of text input in the user's locale, with keys for aiding in the input of email addresses, such as that for the "@" character and the "." character.
numeric	The user agent should display a virtual keyboard capable of numeric input. This keyword is useful for PIN entry.
decimal	The user agent should display a virtual keyboard capable of fractional numeric input. Numeric keys and the format separator for the locale should be shown.
search	The user agent should display a virtual keyboard optimized for search.

The **inputMode** IDL attribute must reflect[p101] the inputmode[p839] content attribute, limited to only known values[p102].

When inputmode[p839] is unspecified (or is in a state not supported by the user agent), the user agent should determine the default virtual keyboard to be shown. Contextual information such as the input type[p514] or pattern[p544] attributes should be used to determine which type of virtual keyboard should be presented to the user.

6.8.8 Input modalities: the enterkeyhint[p840] attribute §[p840]

User agents can support the enterkeyhint[p840] attribute on form controls (such as the value of textarea[p570] elements), or in elements in an editing host[p835] (e.g., using contenteditable[p833]).

The **enterkeyhint** content attribute is an enumerated attribute[p73] that specifies what action label (or icon) to present for the enter key on virtual keyboards. This allows authors to customize the presentation of the enter key in order to make it more helpful for users.

Keyword	Description
enter	The user agent should present a cue for the operation 'enter', typically inserting a new line.
done	The user agent should present a cue for the operation 'done', typically meaning there is nothing more to input and the input method editor (IME) will be closed.
go	The user agent should present a cue for the operation 'go', typically meaning to take the user to the target of the text they typed.
next	The user agent should present a cue for the operation 'next', typically taking the user to the next field that will accept text.
previous	The user agent should present a cue for the operation 'previous', typically taking the user to the previous field that will accept text.
search	The user agent should present a cue for the operation 'search', typically taking the user to the results of searching for the text they have typed.
send	The user agent should present a cue for the operation 'send', typically delivering the text to its target.

The **enterKeyHint** IDL attribute must reflect[p101] the enterkeyhint[p840] content attribute, limited to only known values[p102].

When enterkeyhint[p840] is unspecified (or is in a state not supported by the user agent), the user agent should determine the default action label (or icon) to present. Contextual information such as the inputmode[p839], type[p514], or pattern[p544] attributes should be used to determine which action label (or icon) to present on the virtual keyboard.

6.9 Find-in-page §[p840]

6.9.1 Introduction §[p840]

This section defines **find-in-page** — a common user-agent mechanism which allows users to search through the contents of the page for particular information.

Access to the find-in-page[p840] feature is provided via a **find-in-page interface**. This is a user-agent provided user interface, which allows the user to specify input and the parameters of the search. This interface can appear as a result of a shortcut or a menu selection.

A combination of text input and settings in the find-in-page interface[p840] represents the user **query**. This typically includes the text that the user wants to search for, as well as optional settings (e.g., the ability to restrict the search to whole words only).

The user-agent processes page contents for a given query[p840], and identifies zero or more **matches**, which are content ranges that satisfy the user query[p840].

One of the matches[p840] is identified to the user as the **active match**. It is highlighted and scrolled into view. The user can navigate through the matches[p840] by advancing the active match[p840] using the find-in-page interface[p840].

Issue #3539 tracks standardizing how find-in-page[p840] underlies the currently-unspecified `window.find()` API.

6.9.2 Interaction with details[p627] and hidden=until-found[p805] §[p840]

When find-in-page begins searching for matches, all details[p627] elements in the page which do not have their open[p627] attribute set should have the skipped contents of their second slot become accessible, without modifying the open[p627] attribute, in order to make find-in-page able to search through it. Similarly, all HTML elements with the hidden[p805] attribute in the hidden until found state[p805] should have their skipped contents become accessible without modifying the hidden[p805] attribute in order to make find-in-page able to search through them. After find-in-page finishes searching for matches, the details[p627] elements and the elements with the hidden[p805] attribute in the hidden until found state[p805] should have their contents become skipped again. This entire process must happen synchronously (and so is not observable to users or to author code). [CSSCONTAIN][p1411]

When find-in-page chooses a new active match[p840], perform the following steps:

1. Let *node* be the first node in the active match[p840].
2. Queue a global task[p1073] on the user interaction task source[p1080] given *node*'s relevant global object[p1039] to run the following steps:
    1. Run the ancestor details revealing algorithm[p628] on *node*.
    2. Run the ancestor hidden-until-found revealing algorithm[p807] on *node*.

⚠Warning!

When find-in-page auto-expands a `details`[p627] element like this, it will fire a `toggle`[p1407] event. As with the separate `scroll` event that find-in-page fires, this event could be used by the page to discover what the user is typing into the find-in-page dialog. If the page creates a tiny scrollable area with the current search term and every possible next character the user could type separated by a gap, and observes which one the browser scrolls to, it can add that character to the search term and update the scrollable area to incrementally build the search term. By wrapping each possible next match in a closed `details`[p627] element, the page could listen to `toggle`[p1407] events instead of `scroll` events. This attack could be addressed for both events by not acting on every character the user types into the find-in-page dialog.

6.9.3 Interaction with selection §[p84] 1

The find-in-page process is invoked in the context of a document, and may have an effect on the selection of that document. Specifically, the range that defines the active match[p840] can dictate the current selection. These selection updates, however, can happen at different times during the find-in-page process (e.g. upon the find-in-page interface[p840] dismissal or upon a change in the active match[p840] range).

✔ MDN

6.10 Drag and drop §[p84] 1

This section defines an event-based drag-and-drop mechanism.

This specification does not define exactly what a *drag-and-drop operation* actually is.

On a visual medium with a pointing device, a drag operation could be the default action of a `mousedown` event that is followed by a series of `mousemove` events, and the drop could be triggered by the mouse being released.

When using an input modality other than a pointing device, users would probably have to explicitly indicate their intention to perform a drag-and-drop operation, stating what they wish to drag and where they wish to drop it, respectively.

However it is implemented, drag-and-drop operations must have a starting point (e.g. where the mouse was clicked, or the start of the selection or element that was selected for the drag), may have any number of intermediate steps (elements that the mouse moves over during a drag, or elements that the user picks as possible drop points as they cycle through possibilities), and must either have an end point (the element above which the mouse button was released, or the element that was finally selected), or be canceled. The end point must be the last element selected as a possible drop point before the drop occurs (so if the operation is not canceled, there must be at least one element in the middle step).

6.10.1 Introduction §[p84] 1

This section is non-normative.

To make an element draggable, give the element a `draggable`[p856] attribute, and set an event listener for `dragstart`[p856] that stores the data being dragged.

The event handler typically needs to check that it's not a text selection that is being dragged, and then needs to store data into the `DataTransfer`[p844] object and set the allowed effects (copy, move, link, or some combination).

For example:

```
<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)">
 <li draggable="true" data-value="fruit-apple">Apples</li>
 <li draggable="true" data-value="fruit-orange">Oranges</li>
 <li draggable="true" data-value="fruit-pear">Pears</li>
</ol>
<script>
  var internalDNDType = 'text/x-example'; // set this to something specific to your site
  function dragStartHandler(event) {
    if (event.target instanceof HTMLLIElement) {
      // use the element's data-value="" attribute as the value to be moving:
      event.dataTransfer.setData(internalDNDType, event.target.dataset.value);
      event.dataTransfer.effectAllowed = 'move'; // only allow moves
    } else {
      event.preventDefault(); // don't allow selection to be dragged
    }
  }
</script>
```

To accept a drop, the drop target has to listen to the following events:

1. The dragenter[p856] event handler reports whether or not the drop target is potentially willing to accept the drop, by canceling the event.
2. The dragover[p856] event handler specifies what feedback will be shown to the user, by setting the dropEffect[p845] attribute of the DataTransfer[p844] associated with the event. This event also needs to be canceled.
3. The drop[p856] event handler has a final chance to accept or reject the drop. If the drop is accepted, the event handler must perform the drop operation on the target. This event needs to be canceled, so that the dropEffect[p845] attribute's value can be used by the source. Otherwise, the drop operation is rejected.

For example:

```
<p>Drop your favorite fruits below:</p>
<ol ondragenter="dragEnterHandler(event)" ondragover="dragOverHandler(event)"
    ondrop="dropHandler(event)">
</ol>
<script>
  var internalDNDType = 'text/x-example'; // set this to something specific to your site
  function dragEnterHandler(event) {
    var items = event.dataTransfer.items;
    for (var i = 0; i < items.length; ++i) {
      var item = items[i];
      if (item.kind == 'string' && item.type == internalDNDType) {
        event.preventDefault();
        return;
      }
    }
  }
  function dragOverHandler(event) {
    event.dataTransfer.dropEffect = 'move';
    event.preventDefault();
  }
  function dropHandler(event) {
    var li = document.createElement('li');
    var data = event.dataTransfer.getData(internalDNDType);
    if (data == 'fruit-apple') {
      li.textContent = 'Apples';
    } else if (data == 'fruit-orange') {
      li.textContent = 'Oranges';
    } else if (data == 'fruit-pear') {
```

```
      li.textContent = 'Pears';
    } else {
      li.textContent = 'Unknown Fruit';
    }
    event.target.appendChild(li);
  }
</script>
```

To remove the original element (the one that was dragged) from the display, the dragend[p856] event can be used.

For our example here, that means updating the original markup to handle that event:

```
<p>What fruits do you like?</p>
<ol ondragstart="dragStartHandler(event)" ondragend="dragEndHandler(event)">
 ...as before...
</ol>
<script>
  function dragStartHandler(event) {
    // ...as before...
  }
  function dragEndHandler(event) {
    if (event.dataTransfer.dropEffect == 'move') {
      // remove the dragged element
      event.target.parentNode.removeChild(event.target);
    }
  }
</script>
```

6.10.2 The drag data store §[p843]

The data that underlies a drag-and-drop operation, known as the **drag data store**, consists of the following information:

- A **drag data store item list**, which is a list of items representing the dragged data, each consisting of the following information:

  The drag data item kind

  The kind of data:

  Text

  Text.

  File

  Binary data with a filename.

  The drag data item type string

  A Unicode string giving the type or format of the data, generally given by a MIME type. Some values that are not MIME types are special-cased for legacy reasons. The API does not enforce the use of MIME types; other values can be used as well. In all cases, however, the values are all converted to ASCII lowercase by the API.

  There is a limit of one *text* item per item type string[p843].

  The actual data

  A Unicode or binary string, in some cases with a filename (itself a Unicode string), as per the drag data item kind[p843].

  The drag data store item list[p843] is ordered in the order that the items were added to the list; most recently added last.

- The following information, used to generate the UI feedback during the drag:

  - User-agent-defined default feedback information, known as the **drag data store default feedback**.

- Optionally, a bitmap image and the coordinate of a point within that image, known as the **drag data store bitmap** and **drag data store hot spot coordinate**.

- A **drag data store mode**, which is one of the following:

  Read/write mode

  For the dragstart[p856] event. New data can be added to the drag data store[p843].

  Read-only mode

  For the drop[p856] event. The list of items representing dragged data can be read, including the data. No new data can be added.

  Protected mode

  For all other events. The formats and kinds in the drag data store[p843] list of items representing dragged data can be enumerated, but the data itself is unavailable and no new data can be added.

- A **drag data store allowed effects state**, which is a string.

When a drag data store[p843] is **created**, it must be initialized such that its drag data store item list[p843] is empty, it has no drag data store default feedback[p843], it has no drag data store bitmap[p844] and drag data store hot spot coordinate[p844], its drag data store mode[p844] is protected mode[p844], and its drag data store allowed effects state[p844] is the string "uninitialized[p845]".

6.10.3 The DataTransfer[p844] interface §[p844] 4

✔ MDN

DataTransfer[p844] objects are used to expose the drag data store[p843] that underlies a drag-and-drop operation.

IDL
```
[Exposed=Window]
interface DataTransfer {
  constructor();

  attribute DOMString dropEffect;
  attribute DOMString effectAllowed;

  [SameObject] readonly attribute DataTransferItemList items;

  undefined setDragImage(Element image, long x, long y);

  /* old interface */
  readonly attribute FrozenArray<DOMString> types;
  DOMString getData(DOMString format);
  undefined setData(DOMString format, DOMString data);
  undefined clearData(optional DOMString format);
  [SameObject] readonly attribute FileList files;
};
```

For web developers (non-normative)

***dataTransfer* = new DataTransfer[p845]()**

Creates a new DataTransfer[p844] object with an empty drag data store[p843].

***dataTransfer*.dropEffect[p845] [= *value*]**

Returns the kind of operation that is currently selected. If the kind of operation isn't one of those that is allowed by the effectAllowed[p845] attribute, then the operation will fail.

Can be set, to change the selected operation.

The possible values are "none[p845]", "copy[p845]", "link[p845]", and "move[p845]".

***dataTransfer*.effectAllowed[p845] [= *value*]**

Returns the kinds of operations that are to be allowed.

Can be set (during the dragstart[p856] event), to change the allowed operations.

The possible values are "none[p845]", "copy[p845]", "copyLink[p845]", "copyMove[p845]", "link[p845]", "linkMove[p845]", "move[p845]", "all[p845]", and "uninitialized[p845]",

***dataTransfer*.items[p845]**

Returns a DataTransferItemList[p847] object, with the drag data.

***dataTransfer*.setDragImage[p846](*element, x, y*)**

Uses the given element to update the drag feedback, replacing any previously specified feedback.

***dataTransfer*.types[p846]**

Returns a frozen array listing the formats that were set in the dragstart[p856] event. In addition, if any files are being dragged, then one of the types will be the string "Files".

***data* = *dataTransfer*.getData[p846](*format*)**

Returns the specified data. If there is no such data, returns the empty string.

***dataTransfer*.setData[p846](*format, data*)**

Adds the specified data.

***dataTransfer*.clearData[p846]([*format*])**

Removes the data of the specified formats. Removes all data if the argument is omitted.

***dataTransfer*.files[p847]**

Returns a FileList of the files being dragged, if any.

DataTransfer[p844] objects that are created as part of drag-and-drop events[p856] are only valid while those events are being fired.

A DataTransfer[p844] object is associated with a drag data store[p843] while it is valid.

A DataTransfer[p844] object has an associated **types array**, which is a FrozenArray<DOMString>, initially empty. When the contents of the DataTransfer[p844] object's drag data store item list[p843] change, or when the DataTransfer[p844] object becomes no longer associated with a drag data store[p843], run the following steps:

1. Let *L* be an empty sequence.
2. If the DataTransfer[p844] object is still associated with a drag data store[p843], then:
    1. For each item in the DataTransfer[p844] object's drag data store item list[p843] whose kind[p843] is *text*, add an entry to *L* consisting of the item's type string[p843].
    2. If there are any items in the DataTransfer[p844] object's drag data store item list[p843] whose kind[p843] is *File*, then add an entry to *L* consisting of the string "Files". (This value can be distinguished from the other values because it is not lowercase.)
3. Set the DataTransfer[p844] object's types array[p845] to the result of creating a frozen array from *L*.

The **DataTransfer()** constructor, when invoked, must return a newly created DataTransfer[p844] object initialized as follows:

1. Set the drag data store[p843]'s item list[p843] to be an empty list.
2. Set the drag data store[p843]'s mode[p844] to read/write mode[p844].
3. Set the dropEffect[p845] and effectAllowed[p845] to "none".

The **dropEffect** attribute controls the drag-and-drop feedback that the user is given during a drag-and-drop operation. When the DataTransfer[p844] object is created, the dropEffect[p845] attribute is set to a string value. On getting, it must return its current value. On setting, if the new value is one of "**none**", "**copy**", "**link**", or "**move**", then the attribute's current value must be set to the new value. Other values must be ignored.

The **effectAllowed** attribute is used in the drag-and-drop processing model to initialize the dropEffect[p845] attribute during the dragenter[p856] and dragover[p856] events. When the DataTransfer[p844] object is created, the effectAllowed[p845] attribute is set to a string value. On getting, it must return its current value. On setting, if drag data store[p843]'s mode[p844] is the read/write mode[p844] and the new value is one of "**none**", "**copy**", "**copyLink**", "**copyMove**", "**link**", "**linkMove**", "**move**", "**all**", or "**uninitialized**", then the attribute's current value must be set to the new value. Otherwise it must be left unchanged.

The **items** attribute must return a DataTransferItemList[p847] object associated with the DataTransfer[p844] object.

The **`setDragImage(image, x, y)`** method must run the following steps:

1. If the `DataTransfer`[p844] object is no longer associated with a drag data store[p843], return. Nothing happens.
2. If the drag data store[p843]'s mode[p844] is not the read/write mode[p844], return. Nothing happens.
3. If *image* is an `img`[p338] element, then set the drag data store bitmap[p844] to the element's image (at its natural size); otherwise, set the drag data store bitmap[p844] to an image generated from the given element (the exact mechanism for doing so is not currently specified).
4. Set the drag data store hot spot coordinate[p844] to the given *x*, *y* coordinate.

The **`types`** attribute must return this `DataTransfer`[p844] object's types array[p845].

The **`getData(format)`** method must run the following steps:

1. If the `DataTransfer`[p844] object is no longer associated with a drag data store[p843], then return the empty string.
2. If the drag data store[p843]'s mode[p844] is the protected mode[p844], then return the empty string.
3. Let *format* be the first argument, converted to ASCII lowercase.
4. Let *convert-to-URL* be false.
5. If *format* equals "`text`", change it to "`text/plain`".
6. If *format* equals "`url`", change it to "`text/uri-list`" and set *convert-to-URL* to true.
7. If there is no item in the drag data store item list[p843] whose kind[p843] is *text* and whose type string[p843] is equal to *format*, return the empty string.
8. Let *result* be the data of the item in the drag data store item list[p843] whose kind[p843] is *Plain Unicode string* and whose type string[p843] is equal to *format*.
9. If *convert-to-URL* is true, then parse *result* as appropriate for `text/uri-list` data, and then set *result* to the first URL from the list, if any, or the empty string otherwise. [RFC2483][p1416]
10. Return *result*.

The **`setData(format, data)`** method must run the following steps:

1. If the `DataTransfer`[p844] object is no longer associated with a drag data store[p843], return. Nothing happens.
2. If the drag data store[p843]'s mode[p844] is not the read/write mode[p844], return. Nothing happens.
3. Let *format* be the first argument, converted to ASCII lowercase.
4. If *format* equals "`text`", change it to "`text/plain`".

   If *format* equals "`url`", change it to "`text/uri-list`".
5. Remove the item in the drag data store item list[p843] whose kind[p843] is *text* and whose type string[p843] is equal to *format*, if there is one.
6. Add an item to the drag data store item list[p843] whose kind[p843] is *text*, whose type string[p843] is equal to *format*, and whose data is the string given by the method's second argument.

The **`clearData(format)`** method must run the following steps:

1. If the `DataTransfer`[p844] object is no longer associated with a drag data store[p843], return. Nothing happens.
2. If the drag data store[p843]'s mode[p844] is not the read/write mode[p844], return. Nothing happens.
3. If the method was called with no arguments, remove each item in the drag data store item list[p843] whose kind[p843] is *Plain Unicode string*, and return.
4. Set *format* to *format*, converted to ASCII lowercase.
5. If *format* equals "`text`", change it to "`text/plain`".

   If *format* equals "`url`", change it to "`text/uri-list`".

6. Remove the item in the drag data store item list[p843] whose kind[p843] is *text* and whose type string[p843] is equal to *format*, if there is one.

Note

The clearData()[p846] method does not affect whether any files were included in the drag, so the types[p846] attribute's list might still not be empty after calling clearData()[p846] (it would still contain the "Files" string if any files were included in the drag).

The **files** attribute must return a live[p46] FileList sequence consisting of File objects representing the files found by the following steps. Furthermore, for a given FileList object and a given underlying file, the same File object must be used each time.

1. Start with an empty list *L*.
2. If the DataTransfer[p844] object is no longer associated with a drag data store[p843], the FileList is empty. Return the empty list *L*.
3. If the drag data store[p843]'s mode[p844] is the protected mode[p844], Return the empty list *L*.
4. For each item in the drag data store item list[p843] whose kind[p843] is *File*, add the item's data (the file, in particular its name and contents, as well as its type[p843]) to the list *L*.
5. The files found by these steps are those in the list *L*.

Note

This version of the API does not expose the types of the files during the drag.

✔ MDN

6.10.3.1 The DataTransferItemList[p847] interface §[p847]

Each DataTransfer[p844] object is associated with a DataTransferItemList[p847] object.

IDL

```
[Exposed=Window]
interface DataTransferItemList {
  readonly attribute unsigned long length;
  getter DataTransferItem (unsigned long index);
  DataTransferItem? add(DOMString data, DOMString type);
  DataTransferItem? add(File data);
  undefined remove(unsigned long index);
  undefined clear();
};
```

For web developers (non-normative)

***items*.length**[p848]

Returns the number of items in the drag data store[p843].

***items*[*index*]**

Returns the DataTransferItem[p848] object representing the *index*th entry in the drag data store[p843].

***items*.remove**[p848]**(*index*)**

Removes the *index*th entry in the drag data store[p843].

***items*.clear**[p848]**()**

Removes all the entries in the drag data store[p843].

***items*.add**[p848]**(*data*)**

***items*.add**[p848]**(*data*, *type*)**

Adds a new entry for the given data to the drag data store[p843]. If the data is plain text then a *type* string has to be provided also.

While the DataTransferItemList[p847] object's DataTransfer[p844] object is associated with a drag data store[p843], the DataTransferItemList[p847] object's *mode* is the same as the drag data store mode[p844]. When the DataTransferItemList[p847] object's DataTransfer[p844] object is *not* associated with a drag data store[p843], the DataTransferItemList[p847] object's *mode* is the *disabled mode*. The drag data store[p843] referenced in this section (which is used only when the DataTransferItemList[p847] object is not in the

disabled mode) is the drag data store[p843] with which the DataTransferItemList[p847] object's DataTransfer[p844] object is associated.

The **length** attribute must return zero if the object is in the *disabled mode*; otherwise it must return the number of items in the drag data store item list[p843].

When a DataTransferItemList[p847] object is not in the *disabled mode*, its supported property indices are the indices of the drag data store item list[p843].

To determine the value of an indexed property *i* of a DataTransferItemList[p847] object, the user agent must return a DataTransferItem[p848] object representing the *i*th item in the drag data store[p843]. The same object must be returned each time a particular item is obtained from this DataTransferItemList[p847] object. The DataTransferItem[p848] object must be associated with the same DataTransfer[p844] object as the DataTransferItemList[p847] object when it is first created.

The **add()** method must run the following steps:

1. If the DataTransferItemList[p847] object is not in the *read/write mode*[p844], return null.
2. Jump to the appropriate set of steps from the following list:

   ↪ **If the first argument to the method is a string**

   If there is already an item in the drag data store item list[p843] whose kind[p843] is *text* and whose type string[p843] is equal to the value of the method's second argument, converted to ASCII lowercase, then throw a "NotSupportedError" DOMException.

   Otherwise, add an item to the drag data store item list[p843] whose kind[p843] is *text*, whose type string[p843] is equal to the value of the method's second argument, converted to ASCII lowercase, and whose data is the string given by the method's first argument.

   ↪ **If the first argument to the method is a File**

   Add an item to the drag data store item list[p843] whose kind[p843] is *File*, whose type string[p843] is the type of the File, converted to ASCII lowercase, and whose data is the same as the File's data.

3. Determine the value of the indexed property[p848] corresponding to the newly added item, and return that value (a newly created DataTransferItem[p848] object).

The **remove(*index*)** method must run these steps:

1. If the DataTransferItemList[p847] object is not in the *read/write mode*[p844], throw an "InvalidStateError" DOMException.
2. If the drag data store[p843] does not contain an *index*th item, then return.
3. Remove the *index*th item from the drag data store[p843].

The **clear()** method, if the DataTransferItemList[p847] object is in the *read/write mode*[p844], must remove all the items from the drag data store[p843]. Otherwise, it must do nothing.

6.10.3.2 The DataTransferItem[p848] interface §[p848]

MDN

Each DataTransferItem[p848] object is associated with a DataTransfer[p844] object.

IDL
```
[Exposed=Window]
interface DataTransferItem {
  readonly attribute DOMString kind;
  readonly attribute DOMString type;
  undefined getAsString(FunctionStringCallback? _callback);
  File? getAsFile();
};

callback FunctionStringCallback = undefined (DOMString data);
```

For web developers (non-normative)

***item*.kind**[p849]

Returns the drag data item kind[p843], one of: "string", "file".

***item*.type**[p849]

Returns the drag data item type string[p843].

***item*.getAsString**[p849]**(*callback*)**

Invokes the callback with the string data as the argument, if the drag data item kind[p843] is *text*.

***file* = *item*.getAsFile**[p849]**()**

Returns a `File` object, if the drag data item kind[p843] is *File*.

While the `DataTransferItem`[p848] object's `DataTransfer`[p844] object is associated with a drag data store[p843] and that drag data store[p843]'s drag data store item list[p843] still contains the item that the `DataTransferItem`[p848] object represents, the `DataTransferItem`[p848] object's *mode* is the same as the drag data store mode[p844]. When the `DataTransferItem`[p848] object's `DataTransfer`[p844] object is *not* associated with a drag data store[p843], or if the item that the `DataTransferItem`[p848] object represents has been removed from the relevant drag data store item list[p843], the `DataTransferItem`[p848] object's *mode* is the *disabled mode*. The drag data store[p843] referenced in this section (which is used only when the `DataTransferItem`[p848] object is not in the *disabled mode*) is the drag data store[p843] with which the `DataTransferItem`[p848] object's `DataTransfer`[p844] object is associated.

The **`kind`** attribute must return the empty string if the `DataTransferItem`[p848] object is in the *disabled mode*; otherwise it must return the string given in the cell from the second column of the following table from the row whose cell in the first column contains the drag data item kind[p843] of the item represented by the `DataTransferItem`[p848] object:

Kind	String
Text	`"string"`
File	`"file"`

The **`type`** attribute must return the empty string if the `DataTransferItem`[p848] object is in the *disabled mode*; otherwise it must return the drag data item type string[p843] of the item represented by the `DataTransferItem`[p848] object.

The **`getAsString(callback)`** method must run the following steps:

1. If the *callback* is null, return.
2. If the `DataTransferItem`[p848] object is not in the *read/write mode*[p844] or the *read-only mode*[p844], return. The callback is never invoked.
3. If the drag data item kind[p843] is not *text*, then return. The callback is never invoked.
4. Otherwise, queue a task[p1072] to invoke *callback*, passing the actual data of the item represented by the `DataTransferItem`[p848] object as the argument.

The **`getAsFile()`** method must run the following steps:

1. If the `DataTransferItem`[p848] object is not in the *read/write mode*[p844] or the *read-only mode*[p844], then return null.
2. If the drag data item kind[p843] is not *File*, then return null.
3. Return a new `File` object representing the actual data of the item represented by the `DataTransferItem`[p848] object.

6.10.4 The `DragEvent`[p849] interface § [p849]

The drag-and-drop processing model involves several events. They all use the `DragEvent`[p849] interface.

IDL
```
[Exposed=Window]
interface DragEvent : MouseEvent {
  constructor(DOMString type, optional DragEventInit eventInitDict = {});

  readonly attribute DataTransfer? dataTransfer;
};
```

```
dictionary DragEventInit : MouseEventInit {
  DataTransfer? dataTransfer = null;
};
```

For web developers (non-normative)

***event*.dataTransfer**[p850]

Returns the DataTransfer[p844] object for the event.

Note

Although, for consistency with other event interfaces, the DragEvent[p849] interface has a constructor, it is not particularly useful. In particular, there's no way to create a useful DataTransfer[p844] object from script, as DataTransfer[p844] objects have a processing and security model that is coordinated by the browser during drag-and-drops.

The **dataTransfer** attribute of the DragEvent[p849] interface must return the value it was initialized to. It represents the context information for the event.

When a user agent is required to **fire a DND event** named *e* at an element, using a particular drag data store[p843], and optionally with a specific *related target*, the user agent must run the following steps:

1. Let *dataDragStoreWasChanged* be false.
2. If no specific *related target* was provided, set *related target* to null.
3. Let *window* be the relevant global object[p1039] of the Document[p127] object of the specified target element.
4. If *e* is dragstart[p856], then set the drag data store mode[p844] to the read/write mode[p844] and set *dataDragStoreWasChanged* to true.

   If *e* is drop[p856], set the drag data store mode[p844] to the read-only mode[p844].
5. Let *dataTransfer* be a newly created DataTransfer[p844] object associated with the given drag data store[p843].
6. Set the effectAllowed[p845] attribute to the drag data store[p843]'s drag data store allowed effects state[p844].
7. Set the dropEffect[p845] attribute to "none[p845]" if *e* is dragstart[p856], drag[p856], or dragleave[p856]; to the value corresponding to the current drag operation[p853] if *e* is drop[p856] or dragend[p856]; and to a value based on the effectAllowed[p845] attribute's value and the drag-and-drop source, as given by the following table, otherwise (i.e. if *e* is dragenter[p856] or dragover[p856]):

effectAllowed[p845]	**dropEffect**[p845]
"none[p845]"	"none[p845]"
"copy[p845]"	"copy[p845]"
"copyLink[p845]"	"copy[p845]", or, if appropriate[p850], "link[p845]"
"copyMove[p845]"	"copy[p845]", or, if appropriate[p850], "move[p845]"
"all[p845]"	"copy[p845]", or, if appropriate[p850], either "link[p845]" or "move[p845]"
"link[p845]"	"link[p845]"
"linkMove[p845]"	"link[p845]", or, if appropriate[p850], "move[p845]"
"move[p845]"	"move[p845]"
"uninitialized[p845]" when what is being dragged is a selection from a text control	"move[p845]", or, if appropriate[p850], either "copy[p845]" or "link[p845]"
"uninitialized[p845]" when what is being dragged is a selection	"copy[p845]", or, if appropriate[p850], either "link[p845]" or "move[p845]"
"uninitialized[p845]" when what is being dragged is an a[p252] element with an href[p297] attribute	"link[p845]", or, if appropriate[p850], either "copy[p845]" or "move[p845]"
Any other case	"copy[p845]", or, if appropriate[p850], either "link[p845]" or "move[p845]"

Where the table above provides **possibly appropriate alternatives**, user agents may instead use the listed alternative values if platform conventions dictate that the user has requested those alternate effects.

Example

For example, Windows platform conventions are such that dragging while holding the "alt" key indicates a preference for linking the data, rather than moving or copying it. Therefore, on a Windows system, if "link[p845]" is an option according to the table above while the "alt" key is depressed, the user agent could select that instead of "copy[p845]" or "move[p845]".

8. Let *event* be the result of creating an event using DragEvent[p849].

9. Initialize *event*'s type attribute to *e*, its bubbles attribute to true, its view attribute to *window*, its relatedTarget attribute to *related target*, and its dataTransfer[p850] attribute to *dataTransfer*.

10. If *e* is not dragleave[p856] or dragend[p856], then initialize *event*'s cancelable attribute to true.

11. Initialize *event*'s mouse and key attributes initialized according to the state of the input devices as they would be for user interaction events.

    If there is no relevant pointing device, then initialize *event*'s screenX, screenY, clientX, clientY, and button attributes to 0.

12. Dispatch *event* at the specified target element.

13. Set the drag data store allowed effects state[p844] to the current value of *dataTransfer*'s effectAllowed[p845] attribute. (It can only have changed value if *e* is dragstart[p856].)

14. If *dataDragStoreWasChanged* is true, then set the drag data store mode[p844] back to the protected mode[p844].

15. Break the association between *dataTransfer* and the drag data store[p843].

6.10.5 Processing model §[p851]

When the user attempts to begin a drag operation, the user agent must run the following steps. User agents must act as if these steps were run even if the drag actually started in another document or application and the user agent was not aware that the drag was occurring until it intersected with a document under the user agent's purview.

1. Determine what is being dragged, as follows:

   If the drag operation was invoked on a selection, then it is the selection that is being dragged.

   Otherwise, if the drag operation was invoked on a Document[p127], it is the first element, going up the ancestor chain, starting at the node that the user tried to drag, that has the IDL attribute draggable[p857] set to true. If there is no such element, then nothing is being dragged; return, the drag-and-drop operation is never started.

   Otherwise, the drag operation was invoked outside the user agent's purview. What is being dragged is defined by the document or application where the drag was started.

   Note

   img[p338] elements and a[p252] elements with an href[p297] attribute have their draggable[p857] attribute set to true by default.

2. Create a drag data store[p844]. All the DND events fired subsequently by the steps in this section must use this drag data store[p843].

3. Establish which DOM node is the **source node**, as follows:

   If it is a selection that is being dragged, then the source node[p851] is the Text node that the user started the drag on (typically the Text node that the user originally clicked). If the user did not specify a particular node, for example if the user just told the user agent to begin a drag of "the selection", then the source node[p851] is the first Text node containing a part of the selection.

   Otherwise, if it is an element that is being dragged, then the source node[p851] is the element that is being dragged.

   Otherwise, the source node[p851] is part of another document or application. When this specification requires that an event be dispatched at the source node[p851] in this case, the user agent must instead follow the platform-specific conventions relevant to that situation.

Note

Multiple events are fired on the source node[p851] during the course of the drag-and-drop operation.

4. Determine the **list of dragged nodes**, as follows:

   If it is a selection that is being dragged, then the list of dragged nodes[p852] contains, in tree order, every node that is partially or completely included in the selection (including all their ancestors).

   Otherwise, the list of dragged nodes[p852] contains only the source node[p851], if any.

5. If it is a selection that is being dragged, then add an item to the drag data store item list[p843], with its properties set as follows:

   The drag data item type string[p843]

   "`text/plain`"

   The drag data item kind[p843]

   Text

   The actual data

   The text of the selection

   Otherwise, if any files are being dragged, then add one item per file to the drag data store item list[p843], with their properties set as follows:

   The drag data item type string[p843]

   The MIME type of the file, if known, or "`application/octet-stream`" otherwise.

   The drag data item kind[p843]

   File

   The actual data

   The file's contents and name.

   Note

   Dragging files can currently only happen from outside a navigable[p952], for example from a file system manager application.

   If the drag initiated outside of the application, the user agent must add items to the drag data store item list[p843] as appropriate for the data being dragged, honoring platform conventions where appropriate; however, if the platform conventions do not use MIME types to label dragged data, the user agent must make a best-effort attempt to map the types to MIME types, and, in any case, all the drag data item type strings[p843] must be converted to ASCII lowercase.

   User agents may also add one or more items representing the selection or dragged element(s) in other forms, e.g. as HTML.

6. If the list of dragged nodes[p852] is not empty, then extract the microdata from those nodes into a JSON form[p802], and add one item to the drag data store item list[p843], with its properties set as follows:

   The drag data item type string[p843]

   `application/microdata+json`[p1384]

   The drag data item kind[p843]

   Text

   The actual data

   The resulting JSON string.

7. Run the following substeps:

   1. Let *urls* be an empty list of absolute URLs.

   2. For each *node* in the list of dragged nodes[p852]:

      If the node is an `a`[p252] element with an `href`[p297] attribute

      Add to *urls* the result of parsing[p95] the element's `href`[p297] content attribute relative to the element's node document.

If the node is an img[p338] element with a src[p340] attribute

Add to *urls* the result of parsing[p95] the element's src[p340] content attribute relative to the element's node document.

3. If *urls* is still empty, then return.

4. Let *url string* be the result of concatenating the strings in *urls*, in the order they were added, separated by a U+000D CARRIAGE RETURN U+000A LINE FEED character pair (CRLF).

5. Add one item to the drag data store item list[p843], with its properties set as follows:

The drag data item type string[p843]

text/uri-list[p1409]

The drag data item kind[p843]

Text

The actual data

url string

8. Update the drag data store default feedback[p843] as appropriate for the user agent (if the user is dragging the selection, then the selection would likely be the basis for this feedback; if the user is dragging an element, then that element's rendering would be used; if the drag began outside the user agent, then the platform conventions for determining the drag feedback should be used).

9. Fire a DND event[p850] named dragstart[p856] at the source node[p851].

   If the event is canceled, then the drag-and-drop operation should not occur; return.

   Note

   Since events with no event listeners registered are, almost by definition, never canceled, drag-and-drop is always available to the user if the author does not specifically prevent it.

10. Fire a pointer event at the source node[p851] named pointercancel, and fire any other follow-up events as required by *Pointer Events*. [POINTEREVENTS][p1415]

11. Initiate the drag-and-drop operation[p853] in a manner consistent with platform conventions, and as described below.

    The drag-and-drop feedback must be generated from the first of the following sources that is available:

    1. The drag data store bitmap[p844], if any. In this case, the drag data store hot spot coordinate[p844] should be used as hints for where to put the cursor relative to the resulting image. The values are expressed as distances in CSS pixels from the left side and from the top side of the image respectively. [CSS][p1411]

    2. The drag data store default feedback[p843].

From the moment that the user agent is to **initiate the drag-and-drop operation**, until the end of the drag-and-drop operation, device input events (e.g. mouse and keyboard events) must be suppressed.

During the drag operation, the element directly indicated by the user as the drop target is called the **immediate user selection**. (Only elements can be selected by the user; other nodes must not be made available as drop targets.) However, the immediate user selection[p853] is not necessarily the **current target element**, which is the element currently selected for the drop part of the drag-and-drop operation.

The immediate user selection[p853] changes as the user selects different elements (either by pointing at them with a pointing device, or by selecting them in some other way). The current target element[p853] changes when the immediate user selection[p853] changes, based on the results of event listeners in the document, as described below.

Both the current target element[p853] and the immediate user selection[p853] can be null, which means no target element is selected. They can also both be elements in other (DOM-based) documents, or other (non-web) programs altogether. (For example, a user could drag text to a word-processor.) The current target element[p853] is initially null.

In addition, there is also a **current drag operation**, which can take on the values "**none**", "**copy**", "**link**", and "**move**". Initially, it has the value "none[p853]". It is updated by the user agent as described in the steps below.

User agents must, as soon as the drag operation is initiated[p853] and every 350ms (±200ms) thereafter for as long as the drag operation is ongoing, queue a task[p1072] to perform the following steps in sequence:

1. If the user agent is still performing the previous iteration of the sequence (if any) when the next iteration becomes due, return for this iteration (effectively "skipping missed frames" of the drag-and-drop operation).

2. Fire a DND event[p850] named `drag`[p856] at the source node[p851]. If this event is canceled, the user agent must set the current drag operation[p853] to "`none`[p853]" (no drag operation).

3. If the `drag`[p856] event was not canceled and the user has not ended the drag-and-drop operation, check the state of the drag-and-drop operation, as follows:

    1. If the user is indicating a different immediate user selection[p853] than during the last iteration (or if this is the first iteration), and if this immediate user selection[p853] is not the same as the current target element[p853], then update the current target element[p853] as follows:

        ↪ **If the new immediate user selection[p853] is null**

        Set the current target element[p853] to null also.

        ↪ **If the new immediate user selection[p853] is in a non-DOM document or application**

        Set the current target element[p853] to the immediate user selection[p853].

        ↪ **Otherwise**

        Fire a DND event[p850] named `dragenter`[p856] at the immediate user selection[p853].

        If the event is canceled, then set the current target element[p853] to the immediate user selection[p853].

        Otherwise, run the appropriate step from the following list:

        ↪ **If the immediate user selection[p853] is a text control (e.g., `textarea`[p570], or an `input`[p512] element whose `type`[p514] attribute is in the Text[p519] state) or an editing host[p835] or editable element, and the drag data store item list[p843] has an item with the drag data item type string[p843] "`text/plain`" and the drag data item kind[p843] *text***

        Set the current target element[p853] to the immediate user selection[p853] anyway.

        ↪ **If the immediate user selection[p853] is the body element[p133]**

        Leave the current target element[p853] unchanged.

        ↪ **Otherwise**

        Fire a DND event[p850] named `dragenter`[p856] at the body element[p133], if there is one, or at the `Document`[p127] object, if not. Then, set the current target element[p853] to the body element[p133], regardless of whether that event was canceled or not.

    2. If the previous step caused the current target element[p853] to change, and if the previous target element was not null or a part of a non-DOM document, then fire a DND event[p850] named `dragleave`[p856] at the previous target element, with the new current target element[p853] as the specific *related target*.

    3. If the current target element[p853] is a DOM element, then fire a DND event[p850] named `dragover`[p856] at this current target element[p853].

    If the `dragover`[p856] event is not canceled, run the appropriate step from the following list:

    ↪ **If the current target element[p853] is a text control (e.g., `textarea`[p570], or an `input`[p512] element whose `type`[p514] attribute is in the Text[p519] state) or an editing host[p835] or editable element, and the drag data store item list[p843] has an item with the drag data item type string[p843] "`text/plain`" and the drag data item kind[p843] *text***

    Set the current drag operation[p853] to either "`copy`[p853]" or "`move`[p853]", as appropriate given the platform conventions.

    ↪ **Otherwise**

    Reset the current drag operation[p853] to "`none`[p853]".

    Otherwise (if the `dragover`[p856] event *is* canceled), set the current drag operation[p853] based on the values of the `effectAllowed`[p845] and `dropEffect`[p845] attributes of the `DragEvent`[p849] object's `dataTransfer`[p850] object as they stood after the event dispatch finished, as per the following table:

`effectAllowed`[p845]	`dropEffect`[p845]	Drag operation
"`uninitialized`[p845]", "`copy`[p845]", "`copyLink`[p845]", "`copyMove`[p845]", or "`all`[p845]"	"`copy`[p845]"	"`copy`[p853]"

effectAllowed[p845]	dropEffect[p845]	Drag operation
"uninitialized[p845]", "link[p845]", "copyLink[p845]", "linkMove[p845]", or "all[p845]"	"link[p845]"	"link[p853]"
"uninitialized[p845]", "move[p845]", "copyMove[p845]", "linkMove[p845]", or "all[p845]"	"move[p845]"	"move[p853]"
Any other case		"none[p853]"

4. Otherwise, if the current target element[p853] is not a DOM element, use platform-specific mechanisms to determine what drag operation is being performed (none, copy, link, or move), and set the current drag operation[p853] accordingly.

5. Update the drag feedback (e.g. the mouse cursor) to match the current drag operation[p853], as follows:

Drag operation	Feedback
"copy[p853]"	Data will be copied if dropped here.
"link[p853]"	Data will be linked if dropped here.
"move[p853]"	Data will be moved if dropped here.
"none[p853]"	No operation allowed, dropping here will cancel the drag-and-drop operation.

4. Otherwise, if the user ended the drag-and-drop operation (e.g. by releasing the mouse button in a mouse-driven drag-and-drop interface), or if the drag[p856] event was canceled, then this will be the last iteration. Run the following steps, then stop the drag-and-drop operation:

   1. If the current drag operation[p853] is "none[p853]" (no drag operation), or, if the user ended the drag-and-drop operation by canceling it (e.g. by hitting the Escape key), or if the current target element[p853] is null, then the drag operation failed. Run these substeps:

      1. Let *dropped* be false.

      2. If the current target element[p853] is a DOM element, fire a DND event[p850] named dragleave[p856] at it; otherwise, if it is not null, use platform-specific conventions for drag cancelation.

      3. Set the current drag operation[p853] to "none[p853]".

      Otherwise, the drag operation might be a success; run these substeps:

      1. Let *dropped* be true.

      2. If the current target element[p853] is a DOM element, fire a DND event[p850] named drop[p856] at it; otherwise, use platform-specific conventions for indicating a drop.

      3. If the event is canceled, set the current drag operation[p853] to the value of the dropEffect[p845] attribute of the DragEvent[p849] object's dataTransfer[p850] object as it stood after the event dispatch finished.

         Otherwise, the event is not canceled; perform the event's default action, which depends on the exact target as follows:

         ↪ **If the current target element[p853] is a text control (e.g., textarea[p570], or an input[p512] element whose type[p514] attribute is in the Text[p519] state) or an editing host[p835] or editable element, and the drag data store item list[p843] has an item with the drag data item type string[p843] "text/plain" and the drag data item kind[p843] *text***

         Insert the actual data of the first item in the drag data store item list[p843] to have a drag data item type string[p843] of "text/plain" and a drag data item kind[p843] that is *text* into the text control or editing host[p835] or editable element in a manner consistent with platform-specific conventions (e.g. inserting it at the current mouse cursor position, or inserting it at the end of the field).

         ↪ **Otherwise**

         Reset the current drag operation[p853] to "none[p853]".

   2. Fire a DND event[p850] named dragend[p856] at the source node[p851].

   3. Run the appropriate steps from the following list as the default action of the dragend[p856] event:

      ↪ **If *dropped* is true, the current target element[p853] is a *text control* (see below), the current drag operation[p853] is "move[p853]", and the source of the drag-and-drop operation is a selection in the DOM that is entirely contained within an editing host[p835]**

      Delete the selection.

↪ **If *dropped* is true, the current target element[p853] is a *text control* (see below), the current drag operation[p853] is "move[p853]", and the source of the drag-and-drop operation is a selection in a text control**

The user agent should delete the dragged selection from the relevant text control.

↪ **If *dropped* is false or if the current drag operation[p853] is "none[p853]"**

The drag was canceled. If the platform conventions dictate that this be represented to the user (e.g. by animating the dragged selection going back to the source of the drag-and-drop operation), then do so.

↪ **Otherwise**

The event has no default action.

For the purposes of this step, a *text control* is a `textarea`[p570] element or an `input`[p512] element whose `type`[p514] attribute is in one of the Text[p519], Search[p519], Tel[p519], URL[p520], Email[p521], Password[p523], or Number[p528] states.

Note

User agents are encouraged to consider how to react to drags near the edge of scrollable regions. For example, if a user drags a link to the bottom of the viewport on a long page, it might make sense to scroll the page so that the user can drop the link lower on the page.

Note

This model is independent of which `Document`[p127] object the nodes involved are from; the events are fired as described above and the rest of the processing model runs as described above, irrespective of how many documents are involved in the operation.

6.10.6 Events summary §[p856]

This section is non-normative.

The following events are involved in the drag-and-drop model.

Event name	Target	Cancelable?	Drag data store mode[p844]	`dropEffect`[p845]	Default Action
`dragstart`	Source node[p851]	✓ Cancelable	Read/write mode[p844]	"`none`[p845]"	Initiate the drag-and-drop operation
`drag`	Source node[p851]	✓ Cancelable	Protected mode[p844]	"`none`[p845]"	Continue the drag-and-drop operation
`dragenter`	Immediate user selection[p853] or the body element[p133]	✓ Cancelable	Protected mode[p844]	Based on `effectAllowed` value[p850]	Reject immediate user selection[p853] as potential target element[p853]
`dragleave`	Previous target element[p853]	—	Protected mode[p844]	"`none`[p845]"	None
`dragover`	Current target element[p853]	✓ Cancelable	Protected mode[p844]	Based on `effectAllowed` value[p850]	Reset the current drag operation[p853] to "none"
`drop`	Current target element[p853]	✓ Cancelable	Read-only mode[p844]	Current drag operation[p853]	Varies
`dragend`	Source node[p851]	—	Protected mode[p844]	Current drag operation[p853]	Varies

All of these events bubble, are composed, and the `effectAllowed`[p845] attribute always has the value it had after the `dragstart`[p856] event, defaulting to "`uninitialized`[p845]" in the `dragstart`[p856] event.

6.10.7 The `draggable`[p856] attribute §[p856]

All HTML elements[p45] may have the **`draggable`** content attribute set. The `draggable`[p856] attribute is an enumerated attribute[p73]. It has three states. The first state is *true* and it has the keyword `true`. The second state is *false* and it has the keyword `false`. The third state is *auto*; it has no keywords but it is the *missing value default*[p73] and the *invalid value default*[p73].

The *true* state means the element is draggable; the *false* state means that it is not. The *auto* state uses the default behavior of the

user agent.

An element with a draggable[p856] attribute should also have a title[p154] attribute that names the element for the purpose of non-visual interactions.

For web developers (non-normative)

element.**draggable**[p857] [= *value*]

Returns true if the element is draggable; otherwise, returns false.

Can be set, to override the default and set the draggable[p856] content attribute.

The **draggable** IDL attribute, whose value depends on the content attribute's in the way described below, controls whether or not the element is draggable. Generally, only text selections are draggable, but elements whose draggable[p857] IDL attribute is true become draggable as well.

If an element's draggable[p856] content attribute has the state *true*, the draggable[p857] IDL attribute must return true.

Otherwise, if the element's draggable[p856] content attribute has the state *false*, the draggable[p857] IDL attribute must return false.

Otherwise, the element's draggable[p856] content attribute has the state *auto*. If the element is an img[p338] element, an object[p394] element that represents[p138] an image, or an a[p252] element with an href[p297] content attribute, the draggable[p857] IDL attribute must return true; otherwise, the draggable[p857] IDL attribute must return false.

If the draggable[p857] IDL attribute is set to the value false, the draggable[p856] content attribute must be set to the literal value "`false`". If the draggable[p857] IDL attribute is set to the value true, the draggable[p856] content attribute must be set to the literal value "`true`".

6.10.8 Security risks in the drag-and-drop model §[p857]

User agents must not make the data added to the DataTransfer[p844] object during the dragstart[p856] event available to scripts until the drop[p856] event, because otherwise, if a user were to drag sensitive information from one document to a second document, crossing a hostile third document in the process, the hostile document could intercept the data.

For the same reason, user agents must consider a drop to be successful only if the user specifically ended the drag operation — if any scripts end the drag operation, it must be considered unsuccessful (canceled) and the drop[p856] event must not be fired.

User agents should take care to not start drag-and-drop operations in response to script actions. For example, in a mouse-and-window environment, if a script moves a window while the user has their mouse button depressed, the UA would not consider that to start a drag. This is important because otherwise UAs could cause data to be dragged from sensitive sources and dropped into hostile documents without the user's consent.

User agents should filter potentially active (scripted) content (e.g. HTML) when it is dragged and when it is dropped, using a safelist of known-safe features. Similarly, relative URLs should be turned into absolute URLs to avoid references changing in unexpected ways. This specification does not specify how this is performed.

Example

Consider a hostile page providing some content and getting the user to select and drag and drop (or indeed, copy and paste) that content to a victim page's contenteditable[p833] region. If the browser does not ensure that only safe content is dragged, potentially unsafe content such as scripts and event handlers in the selection, once dropped (or pasted) into the victim site, get the privileges of the victim site. This would thus enable a cross-site scripting attack.

6.11 The popover[p857] attribute §[p857]

All HTML elements[p45] may have the **popover** content attribute set. When specified, the element won't be rendered until it becomes shown, at which point it will be rendered on top of other page content.

Example

The popover[p857] attribute is a global attribute that allows authors flexibility to ensure popover functionality can be applied to elements with the most relevant semantics.

The following demonstrates how one might create a popover sub-navigation list of links, within the global navigation for a website.

```
<ul>
  <li>
    <a href=...>All Products</a>
    <button popovertarget=sub-nav>
     <img src=down-arrow.png alt="Product pages">
    </button>
    <ul popover id=sub-nav>
     <li><a href=...>Shirts</a>
     <li><a href=...>Shoes</a>
     <li><a href=...>Hats etc.</a>
    </ul>
  </li>
  <!-- other list items and links here -->
</ul>
```

When using popover[p857] on elements without accessibility semantics, for instance the div[p251] element, authors should use the appropriate ARIA attributes to ensure the popover is accessible.

Example

The following shows the baseline markup to create a custom menu popover, where the first menuitem will receive keyboard focus when the popover is invoked due to the use of the `autofocus` attribute. Navigating the menuitems with arrow keys and activation behaviors would still need author scripting. Additional requirements for building custom menus widgets are defined in the WAI-ARIA specification.

```
<button popovertarget=m>Actions</button>
<div role=menu id=m popover>
  <button role=menuitem tabindex=-1 autofocus>Edit</button>
  <button role=menuitem tabindex=-1>Hide</button>
  <button role=menuitem tabindex=-1>Delete</button>
</div>
```

A popover can be useful for rendering a status message, confirming the action performed by the user. The following demonstrates how one could reveal a popover in an output[p575] element.

```
<button id=submit>Submit</button>
<p><output><span popover=manual></span></output></p>

<script>
 const sBtn = document.getElementById("submit");
 const outSpan = document.querySelector("output [popover=manual]");
 let successMessage;
 let errorMessage;

 /* define logic for determining success of action
  and determining the appropriate success or error
  messages to use */

 sBtn.addEventListener("click", ()=> {
  if ( success ) {
   outSpan.textContent = successMessage;
  }
  else {
   outSpan.textContent = errorMessage;
  }
```

```
  outSpan.showPopover();

  setTimeout(function () {
   outSpan.hidePopover();
  }, 10000);
 });
</script>
```

Note

Inserting a popover element into an output[p575] element will generally cause screen readers to announce the content when it becomes visible. Depending on the complexity or frequency of the content, this could be either useful or annoying to users of these assistive technologies. Keep this in mind when using the output[p575] element or other ARIA live regions to ensure the best user experience.

The popover[p857] attribute is an enumerated attribute[p73] with the following keywords and states:

Keyword	State	Brief description
auto	**auto**	Closes other popovers when opened; has light dismiss[p867].
The empty string		
manual	**manual**	Does not close other popovers; does not light dismiss[p867].

The popover[p857] attribute's *invalid value default*[p73] is the manual[p859] state and its *missing value default*[p73] is the **no popover** state.

The **popover** IDL attribute must reflect[p101] the popover[p857] attribute, limited to only known values[p102].

Every HTML element[p45] has a **popover visibility state**, initially hidden[p859], with these potential values:

- **hidden**
- **showing**

The Document[p127] has a **popover pointerdown target**, which is an HTML element[p45] or null, initially null.

Every HTML element[p45] has a **popover invoker**, which is an HTML element[p45] or null, initially set to null.

Every HTML element[p45] has a **popover showing or hiding**, which is a boolean, initially set to false.

Every HTML element[p45] has a **popover toggle task**, initially null, which is either null or a struct which has:

Task

A task which fires a ToggleEvent[p868].

Old state

A string which represents the task[p859]'s event's value for the oldState[p868] attribute.

The following attribute change steps, given *element*, *localName*, *oldValue*, *value*, and *namespace*, are used for all HTML elements[p45]:

1. If *namespace* is not null, then return.
2. If *localName* is not popover[p857], then return.
3. If *oldValue* and *value* are in different states[p857], then run the hide popover algorithm[p861] given *element*, true, true, and false.

For web developers (non-normative)

***element*.showPopover[p860]()**

Shows the popover *element* by adding it to the top layer. If *element*'s popover[p857] attribute is in the auto[p859] state, then this will also close all other auto[p859] popovers unless they are an ancestor of *element* according to the topmost popover ancestor[p863] algorithm.

***element*.hidePopover[p861]()**

Hides the popover *element* by removing it from the top layer and applying `display: none` to it.

***element*.togglePopover[p862]()**

If the popover *element* is not showing, then this method shows it. Otherwise, this method hides it. This method returns true if the popover is open after calling it, otherwise false.

The **showPopover()** method steps are to run show popover[p860] given this, true, and null.

To **show popover**, given an HTML element[p45] *element*, a boolean *throwExceptions*, and an HTML element[p45] or null *invoker*:

1. If the result of running check popover validity[p864] given *element*, false, *throwExceptions*, and null is false, then return.
2. Let *document* be *element*'s node document.
3. Assert: *element*'s popover invoker[p859] is null.
4. Set *element*'s popover invoker[p859] to *invoker*.
5. Assert: *element* is not in *document*'s top layer.
6. Let *nestedShow* be *element*'s popover showing or hiding[p859].
7. Set *element*'s popover showing or hiding[p859] to true.
8. Let *cleanupShowingFlag* be the following steps:
    1. If *nestedShow* is false, then set *element*'s popover showing or hiding[p859] to false.
9. If the result of firing an event named `beforetoggle`[p1406], using `ToggleEvent`[p868], with the `cancelable` attribute initialized to true, the `oldState`[p868] attribute initialized to "`closed`", and the `newState`[p868] attribute initialized to "`open`" at *element* is false, then run *cleanupShowingFlag* and return.
10. If the result of running check popover validity[p864] given *element*, false, *throwExceptions*, and *document* is false, then run *cleanupShowingFlag* and return.

    Note

    Check popover validity[p864] is called again because firing the `beforetoggle`[p1406] event could have disconnected this element or changed its `popover`[p857] attribute.

11. Let *shouldRestoreFocus* be false.
12. If *element*'s `popover`[p857] attribute is in the auto[p859] state, then:
    1. Let *originalType* be the value of *element*'s `popover`[p857] attribute.
    2. Let *ancestor* be the result of running the topmost popover ancestor[p863] algorithm given *element*.
    3. If *ancestor* is null, then set *ancestor* to *document*.
    4. Run hide all popovers until[p862] given *ancestor*, false, and not *nestedShow*.
    5. If *originalType* is not equal to the value of *element*'s `popover`[p857] attribute, then throw a `"InvalidStateError" DOMException`.
    6. If the result of running check popover validity[p864] given *element*, false, *throwExceptions*, and *document* is false, then run *cleanupShowingFlag* and return.

        Note

        Check popover validity[p864] is called again because running hide all popovers until[p862] above could have fired the `beforetoggle`[p1406] event, and an event handler could have disconnected this element or changed its `popover`[p857] attribute.

    7. If the result of running topmost auto popover[p864] on *document* is null, then set *shouldRestoreFocus* to true.

        Note

        This ensures that focus is returned to the previously-focused element only for the first popover in a stack.

13. Set *element*'s previously focused element[p638] to null.
14. Let *originallyFocusedElement* be *document*'s focused area of the document[p817]'s DOM anchor[p815].
15. Add an element to the top layer given *element*.
16. Set *element*'s popover visibility state[p859] to showing[p859].
17. Run the popover focusing steps[p864] given *element*.
18. If *shouldRestoreFocus* is true and *element*'s `popover`[p857] attribute is not in the no popover[p859] state, then set *element*'s previously focused element[p638] to *originallyFocusedElement*.
19. Queue a popover toggle event task[p861] given *element*, "`closed`", and "`open`".
20. Run *cleanupShowingFlag*.

To **queue a popover toggle event task** given an element *element*, a string *oldState*, and a string *newState*:

1. If *element*'s popover toggle task[p859] is not null, then:
    1. Set *oldState* to *element*'s popover toggle task[p859]'s old state[p859].
    2. Remove *element*'s popover toggle task[p859]'s task[p859] from its task queue[p1071].
    3. Set *element*'s popover toggle task[p859] to null.
2. Queue an element task[p1073] given the user interaction task source[p1080] and *element* to run the following steps:
    1. fire an event named `toggle`[p1407], using `ToggleEvent`[p868], with the `oldState`[p868] attribute initialized to *oldState*, and the `newState`[p868] attribute initialized to *newState* at *element*.
    2. Set *element*'s popover toggle task[p859] to null.
3. Set *element*'s popover toggle task[p859] to a struct with task[p859] set to the just-queued task[p1071] and old state[p859] set to *oldState*.

The **`hidePopover()`** method steps are:

✔ MDN

1. Run the hide popover algorithm[p861] given this, true, true, and true.

To **hide a popover** given an HTML element[p45] *element*, a boolean *focusPreviousElement*, a boolean *fireEvents*, and a boolean *throwExceptions*:

1. If the result of running check popover validity[p864] given *element*, true, *throwExceptions*, and null is false, then return.
2. Let *document* be *element*'s node document.
3. Let *nestedHide* be *element*'s popover showing or hiding[p859].
4. Set *element*'s popover showing or hiding[p859] to true.
5. If *nestedHide* is true, then set *fireEvents* to false.
6. Let *cleanupHidingFlag* be the following steps:
    1. If *nestedHide* is false, then set *element*'s popover showing or hiding[p859] to false.
7. If *element*'s `popover`[p857] attribute is in the auto[p859] state, then:
    1. Run hide all popovers until[p862] given *element*, *focusPreviousElement*, and *fireEvents*.
    2. If the result of running check popover validity[p864] given *element*, true, and *throwExceptions* is false, then run *cleanupHidingFlag* and return.

    Note

    Check popover validity[p864] is called again because running hide all popovers until[p862] could have disconnected element *or changed its* `popover`[p857] *attribute.*

    3. If the last item in *document*'s auto popover list[p865] is *element*, then break.

8. Set *element*'s popover invoker[p859] to null.
9. If *fireEvents* is true:
    1. Fire an event named `beforetoggle`[p1406], using `ToggleEvent`[p868], with the `oldState`[p868] attribute initialized to "`open`", and the `newState`[p868] attribute initialized to "`closed`" at *element*.
    2. If the result of running check popover validity[p864] given *element*, true, *throwExceptions*, and null is false, then run *cleanupHidingFlag* and return.

       Note

       Check popover validity[p864] is called again because firing the `beforetoggle`[p1406] event could have disconnected element *or changed its `popover`[p857] attribute.*
    3. Request an element to be removed from the top layer given *element*.
10. Otherwise, remove an element from the top layer immediately given *element*.
11. Set *element*'s popover visibility state[p859] to hidden[p859].
12. If *fireEvents* is true, then queue a popover toggle event task[p861] given *element*, "`open`", and "`closed`".
13. Let *previouslyFocusedElement* be *element*'s previously focused element[p638].
14. If *previouslyFocusedElement* is not null, then:
    1. Set *element*'s previously focused element[p638] to null.
    2. If *focusPreviousElement* is true and *document*'s focused area of the document[p817]'s DOM anchor[p815] is a shadow-including inclusive descendant of *element*, then run the focusing steps[p822] for *previouslyFocusedElement*; the viewport should not be scrolled by doing this step.
15. Run *cleanupHidingFlag*.

The **`togglePopover(force)`** method steps are:

1. If this's popover visibility state[p859] is showing[p859], and *force* is not present or false, then run the hide popover algorithm[p861] given this, true, true, and true.
2. Otherwise, if *force* is not present or true, then run show popover[p860] given this true, and null.
3. Otherwise:
    1. Let *expectedToBeShowing* be true if this's popover visibility state[p859] is showing[p859]; otherwise false.
    2. Run check popover validity[p864] given *expectedToBeShowing*, true, and null.
4. Return true if this's popover visibility state[p859] is showing[p859]; otherwise false.

To **hide all popovers until**, given an HTML element[p45] or `Document`[p127] *endpoint*, a boolean *focusPreviousElement*, and a boolean *fireEvents*:

1. Let *document* be *endpoint*'s node document.
2. Let *closeAllOpenPopovers* be an algorithm which performs the following steps:
    1. Let *popover* be *document*'s topmost auto popover[p864].
    2. While *popover* is not null:
        1. Run the hide popover algorithm[p861] given *popover*, *focusPreviousElement*, *fireEvents*, and false.
        2. Set *popover* to *document*'s topmost auto popover[p864].
3. If *endpoint* is a `Document`[p127], then run *closeAllOpenPopovers* and return.
4. Assert: *endpoint*'s `popover`[p857] attribute is in the auto[p859] state.
5. Let *repeatingHide* be false.
6. Perform the following steps at least once:

1. Let *lastToHide* be null.
2. Let *foundEndpoint* be false.
3. For each *popover* in *document*'s auto popover list[p865]:
    1. If *popover* is *endpoint*, then set *foundEndpoint* to true.
    2. Otherwise, if *foundEndpoint* is true, then set *lastToHide* to *popover* and break.
4. If *foundEndpoint* is false, then run *closeAllOpenPopovers* and return.
5. While *lastToHide* is not null and *lastToHide*'s popover visibility state[p859] is showing[p859] and *document*'s auto popover list[p865] is not empty:
    1. Run the hide popover algorithm[p861] given *document*'s auto popover list[p865]'s last element, *focusPreviousElement*, *fireEvents*, and false.
6. Set *repeatingHide* to true if *document*'s auto popover list[p865] contains *endpoint* and *document*'s auto popover list[p865]'s last element is not *endpoint*, otherwise false.
7. If *repeatingHide* is true, then set *fireEvents* to false.

and keep performing them while *repeatingHide* is true.

Note

The hide all popovers until algorithm[p862] is used in several cases to hide all popovers that don't stay open when something happens. For example, during light-dismiss of a popover, this algorithm ensures that we close only the popovers that aren't related to the node clicked by the user.

To **hide all popovers**, given a `Document`[p127] *document*, run hide all popovers until[p862] given *document*, false, and false.

To find the **topmost popover ancestor**, given a `Node` *newPopover*, perform the following steps. They return an HTML element[p45] or null.

Note

The topmost popover ancestor[p863] algorithm will return the topmost (latest in the auto popover list[p865]) ancestor popover for the provided popover. Popovers can be related to each other in several ways, creating a tree of popovers. There are two paths through which one popover (call it the "child" popover) can have a topmost ancestor popover (call it the "parent" popover):

1. *The popovers are nested within each other in the node tree. In this case, the descendant popover is the "child" and its topmost ancestor popover is the "parent".*
2. *An invoking element (e.g., a `button`[p556]) has a `popovertarget`[p865] attribute pointing to a popover. In this case, the popover is the "child", and the popover subtree the invoking element is in is the "parent". The invoker has to be in a popover and reference an open popover.*

In each of the relationships formed above, the parent popover has to be strictly earlier in the auto popover list[p865] than the child popover, or it does not form a valid ancestral relationship. This eliminates non-showing popovers and self-pointers (e.g., a popover containing an invoking element that points back to the containing popover), and it allows for the construction of a well-formed tree from the (possibly cyclic) graph of connections. Only auto[p859] popovers are considered.

1. Let *popoverPositions* be an empty ordered map.
2. Let *index* be 0.
3. Let *document* be *newPopover*'s node document.
4. For each *popover* in *document*'s auto popover list[p865]:
    1. Set *popoverPositions*[*popover*] to *index*.
    2. Increment *index* by 1.
5. Set *popoverPositions*[*newPopover*] to *index*.

6. Increment *index* by 1.
7. Let *topmostPopoverAncestor* be null.
8. Let *checkAncestor* be an algorithm which performs the following steps given *candidate*:
    1. If *candidate* is null, then return.
    2. Let *candidateAncestor* be the result of running nearest inclusive open popover[p864] given *candidate*.
    3. If *candidateAncestor* is null, then return.
    4. Let *candidatePosition* be *popoverPositions*[*candidateAncestor*].
    5. If *topmostPopoverAncestor* is null or *popoverPositions*[*topmostPopoverAncestor*] is less than *candidatePosition*, then set *topmostPopoverAncestor* to *candidateAncestor*.
9. Run *checkAncestor* given *newPopover*'s parent node within the flat tree.
10. Run *checkAncestor* given *newPopover*'s popover invoker[p859].
11. return *topmostPopoverAncestor*.

To find the **nearest inclusive open popover** given a `Node` *node*, perform the following steps. They return an HTML element[p45] or null.

1. Let *currentNode* be *node*.
2. While *currentNode* is not null:
    1. If *currentNode*'s `popover`[p857] attribute is in the auto[p859] state and *currentNode*'s popover visibility state[p859] is showing[p859], then return *currentNode*.
    2. Set *currentNode* to *currentNode*'s parent in the flat tree.
3. Return null.

To **find the topmost auto popover** given a `Document`[p127] *document*, perform the following steps. They return an HTML element[p45] or null.

1. If *document*'s auto popover list[p865] is not empty, then return *document*'s auto popover list[p865]'s last element.
2. Return null.

To perform the **popover focusing steps** for an HTML element[p45] *subject*:

1. If *subject* is a `dialog`[p633] element, then run the dialog focusing steps[p636] given *subject* and return.
2. If *subject* has the `autofocus`[p828] attribute, then let *control* be *subject*.
3. Otherwise, let *control* be the autofocus delegate[p822] for *subject* given "`other`".
4. If *control* is null, then return.
5. Run the focusing steps[p822] given *control*.
6. Let *topDocument* be the active document[p961] of *control*'s node document's browsing context[p961]'s top-level browsing context[p964].
7. If *control*'s node document's origin is not the same[p870] as the origin of *topDocument*, then return.
8. Empty *topDocument*'s autofocus candidates[p829].
9. Set *topDocument*'s autofocus processed flag[p829] to true.

To **check popover validity** for an HTML element[p45] *element* given a boolean *expectedToBeShowing*, a boolean *throwExceptions*, and a `Document`[p127] or null *expectedDocument* perform the following steps. They throw an exception or return a boolean.

1. If *element*'s `popover`[p857] attribute is in the no popover[p859] state, then:
    1. If *throwExceptions* is true, then throw a `"NotSupportedError"` `DOMException`.

2. Return false.

2. If one of the following conditions is true

   - *expectedToBeShowing* is true and *element*'s popover visibility state[p859] is not showing[p859]
   - *expectedToBeShowing* is false and *element*'s popover visibility state[p859] is not hidden[p859]

   then return false.

3. If one of the following conditions is true

   - *element* is not connected
   - *expectedDocument* is not null and *element*'s node document is not *expectedDocument*
   - *element* is a `dialog`[p633] element and its is modal[p638] flag is set to true.
   - *element*'s fullscreen flag is set

   then:

   1. If *throwExceptions* is true, then throw a `"InvalidStateError"` `DOMException`.
   2. Return false.

4. Return true.

To get the **auto popover list** for a `Document`[p127] *document*:

1. Let *popovers* be « ».
2. For each `Element` *element* in *document*'s top layer: if *element*'s `popover`[p857] attribute is in the auto state[p859] and *element*'s popover visibility state[p859] is showing[p859], then append *element* to *popovers*.
3. Return *popovers*.

6.11.1 The popover target attributes §[p865]

Buttons[p505] may have the following content attributes:

- **`popovertarget`**
- **`popovertargetaction`**

If specified, the `popovertarget`[p865] attribute value must be the ID of an element with a `popover`[p857] attribute in the same tree as the button[p505] with the `popovertarget`[p865] attribute.

The `popovertargetaction`[p865] attribute is an enumerated attribute[p73] with the following keywords and states:

Keyword	State	Brief description
`toggle`	**toggle**	Shows or hides the targeted popover element.
`show`	**show**	Shows the targeted popover element.
`hide`	**hide**	Hides the targeted popover element.

The `popovertargetaction`[p865] attribute's *invalid value default*[p73] and *missing value default*[p73] are both the toggle[p865] state.

Note

Whenever possible ensure the popover element is placed immediately after its triggering element in the DOM. Doing so will help ensure that the popover is exposed in a logical programmatic reading order for users of assistive technology, such as screen readers.

Example

The following shows how the popovertarget[p865] attribute in combination with the popovertargetaction[p865] attribute can be used to show and close a popover:

```
<button popovertarget="foo" popovertargetaction="show">
  Show a popover
</button>

<article popover="auto" id="foo">
  This is a popover article!
  <button popovertarget="foo" popovertargetaction="hide">Close</button>
</article>
```

If a popovertargetaction[p865] attribute is not specified, the default action will be to toggle the associated popover. The following shows how only specifying the popovertarget[p865] attribute on its invoking button can toggle a manual popover between its opened and closed states. A manual popover will not light dismiss:

```
<input type="button" popovertarget="foo" value="Toggle the popover">

<div popover=manual id="foo">
  This is a popover!
</div>
```

DOM interface[p143]:

IDL
```
interface mixin PopoverInvokerElement {
  [CEReactions] attribute Element? popoverTargetElement;
  [CEReactions] attribute DOMString popoverTargetAction;
};
```

The **popoverTargetElement** IDL attribute must reflect[p101] the popovertarget[p865] attribute.

The **popoverTargetAction** IDL attribute must reflect[p101] the popovertargetaction[p865] attribute, limited to only known values[p102].

To run the **popover target attribute activation behavior** given a Node *node*:

1. Let *popover* be *node*'s popover target element[p866].
2. If *popover* is null, then return.
3. If *node*'s popovertargetaction[p865] attribute is in the show[p865] state and *popover*'s popover visibility state[p859] is showing[p859], then return.
4. If *node*'s popovertargetaction[p865] attribute is in the hide[p865] state and *popover*'s popover visibility state[p859] is hidden[p859], then return.
5. If *popover*'s popover visibility state[p859] is showing[p859], then run the hide popover algorithm[p861] given *popover*, true, true, and false.
6. Otherwise, if *popover*'s popover visibility state[p859] is hidden[p859] and the result of running check popover validity[p864] given *popover*, false, false, and null is true, then run show popover[p860] given *popover*, false, and *node*.

To get the **popover target element** given a Node *node*, perform the following steps. They return an HTML element[p45] or null.

1. If *node* is not a button[p505], then return null.
2. If *node* is disabled[p592], then return null.
3. If *node* has a form owner[p588] and *node* is a submit button[p505], then return null.
4. Let *popoverElement* be *node*'s popovertarget-associated element[p105].
5. If *popoverElement* is null, then return null.
6. If *popoverElement*'s popover[p857] attribute is in the no popover[p859] state, then return null.

7. Return *popoverElement*.

6.11.2 Popover light dismiss §[p867]

Note

"Light dismiss" means that pressing the Esc key or clicking outside of a popover whose `popover`[p857] attribute is in the auto[p859] state will close the popover.

Canceling popovers: when `Document`[p127] has a topmost auto popover[p864] showing, user agents may provide a user interface that, upon activation, queues an element task[p1073] on the user interaction task source[p1080] given topmost auto popover[p864] to run the hide popover algorithm[p861] given the topmost auto popover[p864], true, true, and false.

To **light dismiss open popovers**, given an `Event` *event*:

1. Assert: *event*'s `isTrusted` attribute is true.
2. Let *target* be *event*'s target.
3. Let *document* be *target*'s node document.
4. Let *topmostPopover* be the result of running topmost auto popover[p864] given *document*.
5. If *topmostPopover* is null, then return.
6. If *event* is a `PointerEvent` and *event*'s `type` is "`pointerdown`", then: set *document*'s popover pointerdown target[p859] to the result of running topmost clicked popover[p867] given *target*.
7. If *event* is a `PointerEvent` and *event*'s `type` is "`pointerup`", then:
    1. Let *ancestor* be the result of running topmost clicked popover[p867] given *target*.
    2. Let *sameTarget* be true if *ancestor* is *document*'s popover pointerdown target[p859].
    3. Set *document*'s popover pointerdown target[p859] to null.
    4. If *ancestor* is null, then set *ancestor* to *document*.
    5. If *sameTarget* is true, then run hide all popovers until[p862] given *ancestor*, false, and true.

Light dismiss open popovers[p867] will be called by the Pointer Events spec when the user clicks or touches anywhere on the page.

To find the **topmost clicked popover**, given a `Node` *node*:

1. Let *clickedPopover* be the result of running nearest inclusive open popover[p864] given *node*.
2. Let *invokerPopover* be the result of running nearest inclusive target popover for invoker[p867] given *node*.
3. Let *getStackPosition* be an algorithm which performs the following steps given an HTML element[p45] *popover*:
    1. Let *popoverList* be *popover*'s node document's auto popover list[p865].
    2. If *popover* is in *popoverList*, then return the index of *popover* in *popoverList* + 1.
    3. Return 0.
4. If the result of running *getStackPosition* given *clickedPopover* is greater than the result of running *getStackPosition* given *invokerPopover*, then return *clickedPopover*.
5. Return *invokerPopover*.

To find the **nearest inclusive target popover for invoker** given a `Node` *node*:

1. Let *currentNode* be *node*.
2. While *currentNode* is not null:

1. Let *targetPopover* be *currentNode*'s popover target element[p866].
2. If *targetPopover* is not null and *targetPopover*'s popover[p857] attribute is in the auto[p859] state and *targetPopover*'s popover visibility state[p859] is showing[p859], then return *targetPopover*.
3. Set *currentNode* to *currentNode*'s ancestor in the flat tree.

6.11.3 The ToggleEvent[p868] interface §[p868]

IDL

```
[Exposed=Window]
interface ToggleEvent : Event {
  constructor(DOMString type, optional ToggleEventInit eventInitDict = {});
  readonly attribute DOMString oldState;
  readonly attribute DOMString newState;
};

dictionary ToggleEventInit : EventInit {
  DOMString oldState = "";
  DOMString newState = "";
};
```

For web developers (non-normative)

***event*.oldState**[p868]

Set to "closed" when transitioning from closed to open, or set to "open" when transitioning from open to closed.

***event*.newState**[p868]

Set to "open" when transitioning from closed to open, or set to "closed" when transitioning from open to closed.

The **oldState** attribute must return the value it was initialized to. It is initialized to "open" if the element with the popover[p857] attribute's popover visibility state[p859] is showing[p859]; otherwise "closed".

The **newState** attribute must return the value it was initialized to. It is initialized to "closed" if the element with the popover[p857] attribute's popover visibility state[p859] is showing[p859]; otherwise "open".

7 Loading web pages §p869

This section describes features that apply most directly to web browsers. Having said that, except where specified otherwise, the requirements defined in this section *do* apply to all user agents, whether they are web browsers or not.

7.1 Supporting concepts §p869

7.1.1 Origins §p869

Origins are the fundamental currency of the web's security model. Two actors in the web platform that share an origin are assumed to trust each other and to have the same authority. Actors with differing origins are considered potentially hostile versus each other, and are isolated from each other to varying degrees.

Example

For example, if Example Bank's web site, hosted at `bank.example.com`, tries to examine the DOM of Example Charity's web site, hosted at `charity.example.org`, a `"SecurityError" DOMException` will be raised.

An **origin** is one of the following:

An *opaque origin*

An internal value, with no serialization it can be recreated from (it is serialized as "`null`" per serialization of an origin[p869]), for which the only meaningful operation is testing for equality.

A *tuple origin*

A tuple[p869] consists of:

- A **scheme** (an ASCII string).
- A **host** (a host).
- A **port** (null or a 16-bit unsigned integer).
- A **domain** (null or a domain). Null unless stated otherwise.

Note

Origins[p869] can be shared, e.g., among multiple `Document`[p127] objects. Furthermore, origins[p869] are generally immutable. Only the domain[p869] of a tuple origin[p869] can be changed, and only through the `document.domain`[p872] API.

The **effective domain** of an origin[p869] *origin* is computed as follows:

1. If *origin* is an opaque origin[p869], then return null.
2. If *origin*'s domain[p869] is non-null, then return *origin*'s domain[p869].
3. Return *origin*'s host[p869].

The **serialization of an origin** is the string obtained by applying the following algorithm to the given origin[p869] *origin*:

1. If *origin* is an opaque origin[p869], then return "`null`".
2. Otherwise, let *result* be *origin*'s scheme[p869].
3. Append "`://`" to *result*.
4. Append *origin*'s host[p869], serialized, to *result*.
5. If *origin*'s port[p869] is non-null, append a U+003A COLON character (:), and *origin*'s port[p869], serialized, to *result*.
6. Return *result*.

Example

The serialization[p869] of ("https", "xn--maraa-rta.example", null, null) is "https://xn--maraa-rta.example".

Note

There used to also be a Unicode serialization of an origin. *However, it was never widely adopted.*

Two origins[p869], *A* and *B*, are said to be **same origin** if the following algorithm returns true:

1. If *A* and *B* are the same opaque origin[p869], then return true.
2. If *A* and *B* are both tuple origins[p869] and their schemes[p869], hosts[p869], and port[p869] are identical, then return true.
3. Return false.

Two origins[p869], *A* and *B*, are said to be **same origin-domain** if the following algorithm returns true:

1. If *A* and *B* are the same opaque origin[p869], then return true.
2. If *A* and *B* are both tuple origins[p869], run these substeps:
    1. If *A* and *B*'s schemes[p869] are identical, and their domains[p869] are identical and non-null, then return true.
    2. Otherwise, if *A* and *B* are same origin[p870] and their domains[p869] are identical and null, then return true.
3. Return false.

Example

A	***B***	**same origin[p870]**	**same origin-domain[p870]**
("https", "example.org", null, null)	("https", "example.org", null, null)	✔	✔
("https", "example.org", 314, null)	("https", "example.org", 420, null)	×	×
("https", "example.org", 314, "example.org")	("https", "example.org", 420, "example.org")	×	✔
("https", "example.org", null, null)	("https", "example.org", null, "example.org")	✔	×
("https", "example.org", null, "example.org")	("http", "example.org", null, "example.org")	×	×

7.1.1.1 Sites §[p870]

A **scheme-and-host** is a tuple of a **scheme** (an ASCII string) and a **host** (a host).

A **site** is an opaque origin[p869] or a scheme-and-host[p870].

To **obtain a site**, given an origin *origin*, run these steps:

1. If *origin* is an opaque origin[p869], then return *origin*.
2. If *origin*'s host[p869]'s registrable domain is null, then return (*origin*'s scheme[p869], *origin*'s host[p869]).
3. Return (*origin*'s scheme[p869], *origin*'s host[p869]'s registrable domain).

Two sites[p870], *A* and *B*, are said to be **same site** if the following algorithm returns true:

1. If *A* and *B* are the same opaque origin[p869], the return true.
2. If *A* or *B* is an opaque origin[p869], then return false.
3. If *A*'s and *B*'s scheme[p870] values are different, then return false.
4. If *A*'s and *B*'s host[p870] values are not equal, then return false.
5. Return true.

The **serialization of a site** is the string obtained by applying the following algorithm to the given site[p870] *site*:

1. If *site* is an opaque origin[p869], then return "`null`".
2. Let *result* be *site*[0].
3. Append "`://`" to *result*.
4. Append *site*[1], serialized, to *result*.
5. Return *result*.

⚠Warning!

It needs to be clear from context that the serialized value is a site, not an origin, as there is not necessarily a syntactic difference between the two. For example, the origin ("`https`", "`shop.example`", null, null) and the site ("`https`", "`shop.example`") have the same serialization: "`https://shop.example`".

Two origins[p869], *A* and *B*, are said to be **schemelessly same site** if the following algorithm returns true:

1. If *A* and *B* are the same opaque origin[p869], then return true.
2. If *A* and *B* are both tuple origins[p869], then:
    1. Let *hostA* be *A*'s host[p869], and let *hostB* be *B*'s host[p869].
    2. If *hostA* equals *hostB* and *hostA*'s registrable domain is null, then return true.
    3. If *hostA*'s registrable domain equals *hostB*'s registrable domain and is non-null, then return true.
3. Return false.

Two origins[p869], *A* and *B*, are said to be **same site** if the following algorithm returns true:

1. Let *siteA* be the result of obtaining a site[p870] given *A*.
2. Let *siteB* be the result of obtaining a site[p870] given *B*.
3. If *siteA* is same site[p870] with *siteB*, then return true.
4. Return false.

Note

Unlike the same origin[p870] and same origin-domain[p870] concepts, for schemelessly same site[p871] and same site[p871], the port[p869] and domain[p869] components are ignored.

⚠Warning!

For the reasons explained in URL, the same site[p871] and schemelessly same site[p871] concepts should be avoided when possible, in favor of same origin[p870] checks.

Example

Given that `wildlife.museum`, `museum`, and `com` are public suffixes and that `example.com` is not:

A	*B*	schemelessly same site[p871]	same site[p871]
("https", "example.com")	("https", "sub.example.com")	✔	✔
("https", "example.com")	("https", "sub.other.example.com")	✔	✔
("https", "example.com")	("http", "non-secure.example.com")	✔	×
("https", "r.wildlife.museum")	("https", "sub.r.wildlife.museum")	✔	✔
("https", "r.wildlife.museum")	("https", "sub.other.r.wildlife.museum")	✔	✔
("https", "r.wildlife.museum")	("https", "other.wildlife.museum")	×	×
("https", "r.wildlife.museum")	("https", "wildlife.museum")	×	×
("https", "wildlife.museum")	("https", "wildlife.museum")	✔	✔
("https", "example.com")	("https", "example.com.")	×	×

(Here we have omitted the port[p869] and domain[p869] components since they are not considered.)

7.1.1.2 Relaxing the same-origin restriction §[p87]

For web developers (non-normative)

***document*.domain**[p872] **[= *domain*]**

Returns the current domain used for security checks.

Can be set to a value that removes subdomains, to change the origin[p869]'s domain[p869] to allow pages on other subdomains of the same domain (if they do the same thing) to access each other. This enables pages on different hosts of a domain to synchronously access each other's DOMs.

In sandboxed `iframe`[p383]s, `Document`[p127]s with opaque origins[p869], and `Document`[p127]s without a browsing context[p961], the setter will throw a `"SecurityError"` exception. In cases where `crossOriginIsolated`[p1095] or `originAgentCluster`[p873] return true, the setter will do nothing.

Avoid using the `document.domain`[p872] setter. It undermines the security protections provided by the same-origin policy. This is especially acute when using shared hosting; for example, if an untrusted third party is able to host an HTTP server at the same IP address but on a different port, then the same-origin protection that normally protects two different sites on the same host will fail, as the ports are ignored when comparing origins after the `document.domain`[p872] setter has been used.

Because of these security pitfalls, this feature is in the process of being removed from the web platform. (This is a long process that takes many years.)

Instead, use `postMessage()`[p1140] or `MessageChannel`[p1143] objects to communicate across origins in a safe manner.

The **`domain`** getter steps are:

1. Let *effectiveDomain* be this's origin's effective domain[p869].
2. If *effectiveDomain* is null, then return the empty string.
3. Return *effectiveDomain*, serialized.

The `domain`[p872] setter steps are:

1. If this's browsing context[p961] is null, then throw a `"SecurityError"` `DOMException`.
2. If this's active sandboxing flag set[p887] has its sandboxed `document.domain` browsing context flag[p885] set, then throw a `"SecurityError"` `DOMException`.
3. Let *effectiveDomain* be this's origin's effective domain[p869].
4. If *effectiveDomain* is null, then throw a `"SecurityError"` `DOMException`.
5. If the given value is not a registrable domain suffix of and is not equal to[p872] *effectiveDomain*, then throw a `"SecurityError"` `DOMException`.
6. If the surrounding agent's agent cluster's is origin-keyed[p1029] is true, then return.
7. Set *this*'s origin's domain[p869] to the result of parsing the given value.

To determine if a scalar value string *hostSuffixString* **is a registrable domain suffix of or is equal to** a host *originalHost*:

1. If *hostSuffixString* is the empty string, then return false.
2. Let *hostSuffix* be the result of parsing *hostSuffixString*.
3. If *hostSuffix* is failure, then return false.
4. If *hostSuffix* does not equal *originalHost*, then:
    1. If *hostSuffix* or *originalHost* is not a domain, then return false.

       Note

       This excludes hosts that are IP addresses.

    2. If *hostSuffix*, prefixed by U+002E (.), does not match the end of *originalHost*, then return false.

3. If one of the following is true

   - *hostSuffix* equals *hostSuffix*'s public suffix
   - *hostSuffix*, prefixed by U+002E (.), matches the end *originalHost*'s public suffix

   then return false. [URL][p1417]

4. Assert: *originalHost*'s public suffix, prefixed by U+002E (.), matches the end of *hostSuffix*.

5. Return true.

Example

hostSuffixString	***originalHost***	**Outcome of is a registrable domain suffix of or is equal to**[p872]	**Notes**
`"0.0.0.0"`	`0.0.0.0`	✔	
`"0x10203"`	`0.1.2.3`	✔	
`"[0::1]"`	`::1`	✔	
`"example.com"`	`example.com`	✔	
`"example.com"`	`example.com.`	×	Trailing dot is significant.
`"example.com."`	`example.com`	×	
`"example.com"`	`www.example.com`	✔	
`"com"`	`example.com`	×	At the time of writing, `com` is a public suffix.
`"example"`	`example`	✔	
`"compute.amazonaws.com"`	`example.compute.amazonaws.com`	×	At the time of writing, `*.compute.amazonaws.com` is a public suffix.
`"example.compute.amazonaws.com"`	`www.example.compute.amazonaws.com`	×	
`"amazonaws.com"`	`www.example.compute.amazonaws.com`	×	
`"amazonaws.com"`	`test.amazonaws.com`	✔	At the time of writing, `amazonaws.com` is a registrable domain.

7.1.2 Origin-keyed agent clusters §[p873]

For web developers (non-normative)

`window.originAgentCluster`[p873]

Returns true if this `Window`[p892] belongs to an agent cluster which is origin[p869]-keyed[p1029], in the manner described in this section.

A `Document`[p127] delivered over a secure context[p1039] can request that it be placed in an origin[p869]-keyed[p1029] agent cluster, by using the `**Origin-Agent-Cluster**` HTTP response header. This header is a structured header whose value must be a boolean. [STRUCTURED-FIELDS][p1417]

Per the processing model in the create and initialize a new `Document` object[p1013], values that are not the structured header boolean true value (i.e., `?1`) will be ignored.

The consequences of using this header are that the resulting `Document`[p127]'s agent cluster key[p1029] is its origin, instead of the corresponding site[p870]. In terms of observable effects, this means that attempting to relax the same-origin restriction[p872] using `document.domain`[p872] will instead do nothing, and it will not be possible to send `WebAssembly.Module` objects to cross-origin `Document`[p127]s (even if they are same site[p871]). Behind the scenes, this isolation can allow user agents to allocate implementation-specific resources corresponding to agent clusters, such as processes or threads, more efficiently.

Note that within a browsing context group[p965], the `Origin-Agent-Cluster`[p873] header can never cause same-origin `Document`[p127] objects to end up in different agent clusters, even if one sends the header and the other doesn't. This is prevented by means of the historical agent cluster key map[p965].

Note

This means that the `originAgentCluster`[p873] getter can return false, even if the header is set, if the header was omitted on a previously-loaded same-origin page in the same browsing context group[p965]. Similarly, it can return true even when the header is not set.

The **`originAgentCluster`** getter steps are to return the surrounding agent's agent cluster's is origin-keyed[p1029].

Note

`Document`[p127]s with an opaque origin[p869] can be considered unconditionally origin-keyed; for them the header has no effect, and the `originAgentCluster`[p873] getter will always return true.

Note

Similarly, `Document`[p127]s whose agent cluster's cross-origin isolation mode[p1029] is not "`none`[p965]" are automatically origin-keyed. The `Origin-Agent-Cluster`[p873] header might be useful as an additional hint to implementations about resource allocation, since the `Cross-Origin-Opener-Policy`[p875] and `Cross-Origin-Embedder-Policy`[p883] headers used to achieve cross-origin isolation are more about ensuring that everything in the same address space opts in to being there. But adding it would have no additional observable effects on author code.

7.1.3 Cross-origin opener policies §[p874]

A **cross-origin opener policy value** allows a document which is navigated to in a top-level browsing context[p964] to force the creation of a new top-level browsing context[p964], and a corresponding group[p965]. The possible values are:

"`unsafe-none`"

This is the (current) default and means that the document will occupy the same top-level browsing context[p964] as its predecessor, unless that document specified a different cross-origin opener policy[p874].

"`same-origin-allow-popups`"

This forces the creation of a new top-level browsing context[p964] for the document, unless its predecessor specified the same cross-origin opener policy[p874] and they are same origin[p870].

"`same-origin`"

This behaves the same as "`same-origin-allow-popups`[p874]", with the addition that any auxiliary browsing context[p961] created needs to contain same origin[p870] documents that also have the same cross-origin opener policy[p874] or it will appear closed to the opener.

"`same-origin-plus-COEP`"

This behaves the same as "`same-origin`[p874]", with the addition that it sets the (new) top-level browsing context[p964]'s group[p965]'s cross-origin isolation mode[p965] to one of "`logical`[p965]" or "`concrete`[p965]".

Note

"`same-origin-plus-COEP`[p874]" cannot be directly set via the `Cross-Origin-Opener-Policy`[p875] header, but results from a combination of setting both `Cross-Origin-Opener-Policy`[p875]: `same-origin`[p874] and a `Cross-Origin-Embedder-Policy`[p883] header whose value is compatible with cross-origin isolation[p883] together.

A **cross-origin opener policy** consists of:

- A **value**, which is a cross-origin opener policy value[p874], initially "`unsafe-none`[p874]".
- A **reporting endpoint**, which is string or null, initially null.
- A **report-only value**, which is a cross-origin opener policy value[p874], initially "`unsafe-none`[p874]".
- A **report-only reporting endpoint**, which is a string or null, initially null.

To **match cross-origin opener policy values**, given a cross-origin opener policy value[p874] *A*, an origin[p869] *originA*, a cross-origin opener policy value[p874] *B*, and an origin[p869] *originB*:

1. If *A* is "`unsafe-none`[p874]" and *B* is "`unsafe-none`[p874]", then return true.
2. If *A* is "`unsafe-none`[p874]" or *B* is "`unsafe-none`[p874]", then return false.
3. If *A* is *B* and *originA* is same origin[p870] with *originB*, then return true.
4. Return false.

7.1.3.1 The headers §[p875]

A Document[p127]'s cross-origin opener policy[p128] is derived from the `Cross-Origin-Opener-Policy` and `Cross-Origin-Opener-Policy-Report-Only` HTTP response headers. These headers are structured headers whose value must be a token. [STRUCTURED-FIELDS][p1417]

The valid token values are the opener policy values[p874]. The token may also have attached parameters; of these, the "**report-to**" parameter can have a valid URL string identifying an appropriate reporting endpoint. [REPORTING][p1414]

Note

Per the processing model described below, user agents will ignore this header if it contains an invalid value. Likewise, user agents will ignore this header if the value cannot be parsed as a token.

To **obtain a cross-origin opener policy** given a response *response* and an environment[p1031] *reservedEnvironment*:

1. Let *policy* be a new cross-origin opener policy[p874].
2. If *reservedEnvironment* is a non-secure context[p1039], then return *policy*.
3. Let *parsedItem* be the result of getting a structured field value given `Cross-Origin-Opener-Policy`[p875] and "`item`" from *response*'s header list.
4. If *parsedItem* is not null, then:
    1. If *parsedItem*[0] is "`same-origin`[p874]", then:
        1. Let *coep* be the result of obtaining a cross-origin embedder policy[p883] from *response* and *reservedEnvironment*.
        2. If *coep*'s value[p883] is compatible with cross-origin isolation[p883], then set *policy*'s value[p874] to "`same-origin-plus-COEP`[p874]".
        3. Otherwise, set *policy*'s value[p874] to "`same-origin`[p874]".
    2. If *parsedItem*[0] is "`same-origin-allow-popups`[p874]", then set *policy*'s value[p874] to "`same-origin-allow-popups`[p874]".
    3. If *parsedItem*[1]["`report-to`[p875]"] exists and it is a string, then set *policy*'s reporting endpoint[p874] to *parsedItem*[1]["`report-to`[p875]"].
5. Set *parsedItem* to the result of getting a structured field value given `Cross-Origin-Opener-Policy-Report-Only`[p875] and "`item`" from *response*'s header list.
6. If *parsedItem* is not null, then:
    1. If *parsedItem*[0] is "`same-origin`[p874]", then:
        1. Let *coep* be the result of obtaining a cross-origin embedder policy[p883] from *response* and *reservedEnvironment*.
        2. If *coep*'s value[p883] is compatible with cross-origin isolation[p883] or *coep*'s report-only value[p883] is compatible with cross-origin isolation[p883], then set *policy*'s report-only value[p874] to "`same-origin-plus-COEP`[p874]".

            Note

            Report only COOP also considers report-only COEP to assign the special "`same-origin-plus-COEP`[p874]" value. This allows developers more freedom in the order of deployment of COOP and COEP.

        3. Otherwise, set *policy*'s report-only value[p874] to "`same-origin`[p874]".
    2. If *parsedItem*[0] is "`same-origin-allow-popups`[p874]", then set *policy*'s report-only value[p874] to "`same-origin-allow-popups`[p874]".
    3. If *parsedItem*[1]["`report-to`[p875]"] exists and it is a string, then set *policy*'s report-only reporting endpoint[p874] to *parsedItem*[1]["`report-to`[p875]"].

7. Return *policy*.

7.1.3.2 Browsing context group switches due to cross-origin opener policy §[p876]

To **check if COOP values require a browsing context group switch**, given a boolean *isInitialAboutBlank*, two origins[p869] *responseOrigin* and *activeDocumentNavigationOrigin*, and two cross-origin opener policy values[p874] *responseCOOPValue* and *activeDocumentCOOPValue*:

1. If the result of matching[p874] *activeDocumentCOOPValue*, *activeDocumentNavigationOrigin*, *responseCOOPValue*, and *responseOrigin* is true, return false.

2. If all of the following are true:

   - *isInitialAboutBlank*;
   - *activeDocumentCOOPValue*'s value[p874] is "`same-origin-allow-popups`[p874]"; and
   - *responseCOOPValue* is "`unsafe-none`[p874]"

   then return false.

3. Return true.

To **check if enforcing report-only COOP would require a browsing context group switch**, given a boolean *isInitialAboutBlank*, two origins[p869] *responseOrigin*, *activeDocumentNavigationOrigin*, and two cross-origin opener policies[p874] *responseCOOP* and *activeDocumentCOOP*:

1. If the result of checking if COOP values require a browsing context group switch[p876] given *isInitialAboutBlank*, *responseOrigin*, *activeDocumentNavigationOrigin*, *responseCOOP*'s report-only value[p874] and *activeDocumentCOOPReportOnly*'s report-only value[p874] is false, then return false.

   Note

   Matching report-only policies allows a website to specify the same report-only cross-origin opener policy on all its pages and not receive violation reports for navigations between these pages.

2. If the result of checking if COOP values require a browsing context group switch[p876] given *isInitialAboutBlank*, *responseOrigin*, *activeDocumentNavigationOrigin*, *responseCOOP*'s value[p874] and *activeDocumentCOOPReportOnly*'s report-only value[p874] is true, then return true.

3. If the result of checking if COOP values require a browsing context group switch[p876] given *isInitialAboutBlank*, *responseOrigin*, *activeDocumentNavigationOrigin*, *responseCOOP*'s report-only value[p874] and *activeDocumentCOOPReportOnly*'s value[p874] is true, then return true.

4. Return false.

A **cross-origin opener policy enforcement result** is a struct with the following items:

- A boolean **needs a browsing context group switch**, initially false.
- A boolean **would need a browsing context group switch due to report-only**, initially false.
- A URL **url**.
- An origin[p869] **origin**.
- A cross-origin opener policy[p874] **cross-origin opener policy**.
- A boolean **current context is navigation source**, initially false.

To **enforce a response's cross-origin opener policy**, given a browsing context[p961] *browsingContext*, a URL *responseURL*, an origin[p869] *responseOrigin*, a cross-origin opener policy[p874] *responseCOOP*, a cross-origin opener policy enforcement result[p876] *currentCOOPEnforcementResult*, and a referrer *referrer*:

1. Let *newCOOPEnforcementResult* be a new cross-origin opener policy enforcement result[p876] with

   needs a browsing context group switch[p876]
   currentCOOPEnforcementResult's needs a browsing context group switch[p876]

would need a browsing context group switch due to report-only[p876]
currentCOOPEnforcementResult's would need a browsing context group switch due to report-only[p876]
url[p876]
responseURL
origin[p876]
responseOrigin
cross-origin opener policy[p876]
responseCOOP
current context is navigation source[p876]
true

2. Let *isInitialAboutBlank* be *browsingContext*'s active document[p961]'s is initial `about:blank`[p128].

3. If *isInitialAboutBlank* is true and *browsingContext*'s initial URL[p961] is null, set *browsingContext*'s initial URL[p961] to *responseURL*.

4. If the result of checking if COOP values require a browsing context group switch[p876] given *isInitialAboutBlank*, *currentCOOPEnforcementResult*'s cross-origin opener policy[p876]'s value[p874], *currentCOOPEnforcementResult*'s origin[p876], *responseCOOP*'s value[p874], and *responseOrigin* is true, then:

    1. Set *newCOOPEnforcementResult*'s needs a browsing context group switch[p876] to true.

    2. If *browsingContext*'s group[p965]'s browsing context set[p965]'s size is greater than 1, then:

        1. Queue a violation report for browsing context group switch when navigating to a COOP response[p879] with *responseCOOP*, "`enforce`", *responseURL*, *currentCOOPEnforcementResult*'s url[p876], *currentCOOPEnforcementResult*'s origin[p876], *responseOrigin*, and *referrer*.

        2. Queue a violation report for browsing context group switch when navigating away from a COOP response[p879] with *currentCOOPEnforcementResult*'s cross-origin opener policy[p876], "`enforce`", *currentCOOPEnforcementResult*'s url[p876], *responseURL*, *currentCOOPEnforcementResult*'s origin[p876], *responseOrigin*, and *currentCOOPEnforcementResult*'s current context is navigation source[p876].

5. If the result of checking if enforcing report-only COOP would require a browsing context group switch[p876] given *isInitialAboutBlank*, *responseOrigin*, *currentCOOPEnforcementResult*'s origin[p876], *responseCOOP*, and *currentCOOPEnforcementResult*'s cross-origin opener policy[p876], is true, then:

    1. Set *result*'s would need a browsing context group switch due to report-only[p876] to true.

    2. If *browsingContext*'s group[p965]'s browsing context set[p965]'s size is greater than 1, then:

        1. Queue a violation report for browsing context group switch when navigating to a COOP response[p879] with *responseCOOP*, "`reporting`", *responseURL*, *currentCOOPEnforcementResult*'s url[p876], *currentCOOPEnforcementResult*'s origin[p876], *responseOrigin*, and *referrer*.

        2. Queue a violation report for browsing context group switch when navigating away from a COOP response[p879] with *currentCOOPEnforcementResult*'s cross-origin opener policy[p876], "`reporting`", *currentCOOPEnforcementResult*'s url[p876], *responseURL*, *currentCOOPEnforcementResult*'s origin[p876], *responseOrigin*, and *currentCOOPEnforcementResult*'s current context is navigation source[p876].

6. Return *newCOOPEnforcementResult*.

To **obtain a browsing context to use for a navigation response**, given a browsing context[p961] *browsingContext*, a sandboxing flag set[p885] *sandboxFlags*, a cross-origin opener policy[p874] *navigationCOOP*, and a cross-origin opener policy enforcement result[p876] *coopEnforcementResult*:

1. If *browsingContext* is not a top-level browsing context[p964], then return *browsingContext*.

2. If *coopEnforcementResult*'s needs a browsing context group switch[p876] is false, then:

    1. If *coopEnforcementResult*'s would need a browsing context group switch due to report-only[p876] is true, set *browsing context*'s virtual browsing context group ID[p961] to a new unique identifier.

    2. Return *browsingContext*.

3. Let *newBrowsingContext* be the first return value of creating a new top-level browsing context and document[p963].

Note

In this case we are going to perform a browsing context group swap. browsingContext *will not be used by the new* Document[p127] *that we are about to create*[p1013]*. If it is not used by other* Document[p127]*s either (such as ones in the back/forward cache), then the user agent might destroy it*[p966] *at this point.*

4. If *navigationCOOP*'s value[p874] is "same-origin-plus-COEP[p874]", then set *newBrowsingContext*'s group[p965]'s cross-origin isolation mode[p965] to either "logical[p965]" or "concrete[p965]". The choice of which is implementation-defined.

   Note

   It is difficult on some platforms to provide the security properties required by the cross-origin isolated capability[p1032]*. "concrete*[p965]*" grants access to it and "logical*[p965]*" does not.*

5. If *sandboxFlags* is not empty, then:

   1. Assert *navigationCOOP*'s value[p874] is "unsafe-none[p874]".
   2. Assert: *newBrowsingContext*'s popup sandboxing flag set[p887] is empty.
   3. Set *newBrowsingContext*'s popup sandboxing flag set[p887] to a clone of *sandboxFlags*.

6. Return *newBrowsingContext*.

7.1.3.3 Reporting §[p878]

An **accessor-accessed relationship** is an enum that describes the relationship between two browsing contexts[p961] between which an access happened. It can take the following values:

accessor is opener

The accessor browsing context[p961] or one of its ancestors[p964] is the opener browsing context[p961] of the accessed browsing context[p961]'s top-level browsing context[p964].

accessor is openee

The accessed browsing context[p961] or one of its ancestors[p964] is the opener browsing context[p961] of the accessor browsing context[p961]'s top-level browsing context[p964].

none

There is no opener relationship between the accessor browsing context[p961], the accessor browsing context[p961], or any of their ancestors[p964].

To **check if an access between two browsing contexts should be reported**, given two browsing contexts[p961] *accessor* and *accessed*, a JavaScript property name *P*, and an environment settings object[p1032] *environment*:

1. If *P* is not a cross-origin accessible window property name[p890], then return.
2. Assert: *accessor*'s active document[p961] and *accessed*'s active document[p961] are both fully active[p966].
3. Let *accessorTopDocument* be *accessor*'s top-level browsing context[p964]'s active document[p961].
4. Let *accessorInclusiveAncestorOrigins* be the list obtained by taking the origin of the active document[p952] of each of *accessor*'s active document[p961]'s inclusive ancestor navigables[p957].
5. Let *accessedTopDocument* be *accessed*'s top-level browsing context[p964]'s active document[p961].
6. Let *accessedInclusiveAncestorOrigins* be the list obtained by taking the origin of the active document[p952] of each of *accessed*'s active document[p961]'s inclusive ancestor navigables[p957].
7. If any of *accessorInclusiveAncestorOrigins* are not same origin[p870] with *accessorTopDocument*'s origin, or if any of *accessedInclusiveAncestorOrigins* are not same origin[p870] with *accessedTopDocument*'s origin, then return.

   Note

   This avoids leaking information about cross-origin iframes to a top level frame with cross-origin opener policy reporting.

8. If *accessor*'s top-level browsing context[p964]'s virtual browsing context group ID[p961] is *accessed*'s top-level browsing

context[p964]'s virtual browsing context group ID[p961], then return.

9. Let *accessorAccessedRelationship* be a new accessor-accessed relationship[p878] with value none[p878].

10. If *accessed*'s top-level browsing context[p964]'s opener browsing context[p961] is *accessor* or is an ancestor[p964] of *accessor*, then set *accessorAccessedRelationship* to accessor is opener[p878].

11. If *accessor*'s top-level browsing context[p964]'s opener browsing context[p961] is *accessed* or is an ancestor[p964] of *accessed*, then set *accessorAccessedRelationship* to accessor is openee[p878].

12. Queue violation reports for accesses[p880], given *accessorAccessedRelationship*, *accessorTopDocument*'s cross-origin opener policy[p128], *accessedTopDocument*'s cross-origin opener policy[p128], *accessor*'s active document[p961]'s URL, *accessed*'s active document[p961]'s URL, *accessor*'s top-level browsing context[p964]'s initial URL[p961], *accessed*'s top-level browsing context[p964]'s initial URL[p961], *accessor*'s active document[p961]'s origin, *accessed*'s active document[p961]'s origin, *accessor*'s top-level browsing context[p964]'s opener origin at creation[p961], *accessed*'s top-level browsing context[p964]'s opener origin at creation[p961], *accessorTopDocument*'s referrer[p129], *accessedTopDocument*'s referrer[p129], *P*, and *environment*.

To **sanitize a URL to send in a report** given a URL *url*:

1. Let *sanitizedURL* be a copy of *url*.

2. Set the username given *sanitizedURL* and the empty string.

3. Set the password given *sanitizedURL* and the empty string.

4. Return the serialization of *sanitizedURL* with *exclude fragment* set to true.

To **queue a violation report for browsing context group switch when navigating to a COOP response** given a cross-origin opener policy[p874] *coop*, a string *disposition*, a URL *coopURL*, a URL *previousResponseURL*, two origins[p869] *coopOrigin* and *previousResponseOrigin*, and a referrer *referrer*:

1. If *coop*'s reporting endpoint[p874] is null, return.

2. Let *coopValue* be *coop*'s value[p874].

3. If *disposition* is "`reporting`", then set *coopValue* to *coop*'s report-only value[p874].

4. Let *serializedReferrer* be an empty string.

5. If *referrer* is a URL, set *serializedReferrer* to the serialization of *referrer*.

6. Let *body* be a new object containing the following properties:

key	value
disposition	*disposition*
effectivePolicy	*coopValue*
previousResponseURL	If *coopOrigin* and *previousResponseOrigin* are same origin[p870] this is the sanitization[p879] of *previousResponseURL*, null otherwise.
referrer	*serializedReferrer*
type	"`navigation-to-response`"

7. Queue *body* as "`coop`" for *coop*'s reporting endpoint[p874] with *coopURL*.

To **queue a violation report for browsing context group switch when navigating away from a COOP response** given a cross-origin opener policy[p874] *coop*, a string *disposition*, a URL *coopURL*, a URL *nextResponseURL*, two origins[p869] *coopOrigin* and *nextResponseOrigin*, and a boolean *isCOOPResponseNavigationSource*:

1. If *coop*'s reporting endpoint[p874] is null, return.

2. Let *coopValue* be *coop*'s value[p874].

3. If *disposition* is "`reporting`", then set *coopValue* to *coop*'s report-only value[p874].

4. Let *body* be a new object containing the following properties:

key	value
disposition	*disposition*
effectivePolicy	*coopValue*

key	value
nextResponseURL	If *coopOrigin* and *nextResponseOrigin* are same origin[p870] or *isCOOPResponseNavigationSource* is true, this is the sanitization[p879] of *previousResponseURL*, null otherwise.
type	"navigation-from-response"

5. Queue *body* as "coop" for *coop*'s reporting endpoint[p874] with *coopURL*.

To **queue violation reports for accesses**, given an accessor-accessed relationship[p878] *accessorAccessedRelationship*, two cross-origin opener policies[p874] *accessorCOOP* and *accessedCOOP*, four URLs *accessorURL*, *accessedURL*, *accessorInitialURL*, *accessedInitialURL*, four origins[p869] *accessorOrigin*, *accessedOrigin*, *accessorCreatorOrigin* and *accessedCreatorOrigin*, two referrers[p129] *accessorReferrer* and *accessedReferrer*, a string *propertyName*, and an environment settings object[p1032] *environment*:

1. If *coop*'s reporting endpoint[p874] is null, return.
2. Let *coopValue* be *coop*'s value[p874].
3. If *disposition* is "reporting", then set *coopValue* to *coop*'s report-only value[p874].
4. If *accessorAccessedRelationship* is accessor is opener[p878]:
    1. Queue a violation report for access to an opened window[p881], given *accessorCOOP*, *accessorURL*, *accessedURL*, *accessedInitialURL*, *accessorOrigin*, *accessedOrigin*, *accessedCreatorOrigin*, *propertyName*, and *environment*.
    2. Queue a violation report for access from the opener[p881], given *accessedCOOP*, *accessedURL*, *accessorURL*, *accessedOrigin*, *accessorOrigin*, *propertyName*, and *accessedReferrer*.
5. Otherwise, if *accessorAccessedRelationship* is accessor is openee[p878]:
    1. Queue a violation report for access to the opener[p880], given *accessorCOOP*, *accessorURL*, *accessedURL*, *accessorOrigin*, *accessedOrigin*, *propertyName*, *accessorReferrer*, and *environment*.
    2. Queue a violation report for access from an opened window[p882], given *accessedCOOP*, *accessedURL*, *accessorURL*, *accessorInitialURL*, *accessedOrigin*, *accessorOrigin*, *accessorCreatorOrigin*, and *propertyName*.
6. Otherwise:
    1. Queue a violation report for access to another window[p881], given *accessorCOOP*, *accessorURL*, *accessedURL*, *accessorOrigin*, *accessedOrigin*, *propertyName*, and *environment*
    2. Queue a violation report for access from another window[p882], given *accessedCOOP*, *accessedURL*, *accessorURL*, *accessedOrigin*, *accessorOrigin*, and *propertyName*.

To **queue a violation report for access to the opener**, given a cross-origin opener policy[p874] *coop*, two URLs *coopURL* and *openerURL*, two origins[p869] *coopOrigin* and *openerOrigin*, a string *propertyName*, a referrer *referrer*, and an environment settings object[p1032] *environment*:

1. Let *sourceFile*, *lineNumber* and *columnNumber* be the relevant script URL and problematic position which triggered this report.
2. Let *serializedReferrer* be an empty string.
3. If *referrer* is a URL, set *serializedReferrer* to the serialization of *referrer*.
4. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	*coop*'s report-only value[p874]
property	*propertyName*
openerURL	If *coopOrigin* and *openerOrigin* are same origin[p870], this is the sanitization[p879] of *openerURL*, null otherwise.
referrer	*serializedReferrer*
sourceFile	*sourceFile*
lineNumber	*lineNumber*
columnNumber	*columnNumber*
type	"access-to-opener"

5. Queue *body* as "coop" for *coop*'s reporting endpoint[p874] with *coopURL* and *environment*.

To **queue a violation report for access to an opened window**, given a cross-origin opener policy[p874] *coop*, three URLs *coopURL*, *openedWindowURL* and *initialWindowURL*, three origins[p869] *coopOrigin*, *openedWindowOrigin*, and *openerInitialOrigin*, a string *propertyName*, and an environment settings object[p1032] *environment*:

1. Let *sourceFile*, *lineNumber* and *columnNumber* be the relevant script URL and problematic position which triggered this report.

2. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	*coop*'s report-only value[p874]
property	*propertyName*
openedWindowURL	If *coopOrigin* and *openedWindowOrigin* are same origin[p870], this is the sanitization[p879] of *openedWindowURL*, null otherwise.
openedWindowInitialURL	If *coopOrigin* and *openerInitialOrigin* are same origin[p870], this is the sanitization[p879] of *initialWindowURL*, null otherwise.
sourceFile	*sourceFile*
lineNumber	*lineNumber*
columnNumber	*columnNumber*
type	"access-to-opener"

3. Queue *body* as "coop" for *coop*'s reporting endpoint[p874] with *coopURL* and *environment*.

To **queue a violation report for access to another window**, given a cross-origin opener policy[p874] *coop*, two URLs *coopURL* and *otherURL*, two origins[p869] *coopOrigin* and *otherOrigin*, a string *propertyName*, and an environment settings object[p1032] *environment*:

1. Let *sourceFile*, *lineNumber* and *columnNumber* be the relevant script URL and problematic position which triggered this report.

2. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	*coop*'s report-only value[p874]
property	*propertyName*
otherURL	If *coopOrigin* and *otherOrigin* are same origin[p870], this is the sanitization[p879] of *otherURL*, null otherwise.
sourceFile	*sourceFile*
lineNumber	*lineNumber*
columnNumber	*columnNumber*
type	"access-to-opener"

3. Queue *body* as "coop" for *coop*'s reporting endpoint[p874] with *coopURL* and *environment*.

To **queue a violation report for access from the opener**, given a cross-origin opener policy[p874] *coop*, two URLs *coopURL* and *openerURL*, two origins[p869] *coopOrigin* and *openerOrigin*, a string *propertyName*, and a referrer *referrer*:

1. If *coop*'s reporting endpoint[p874] is null, return.

2. Let *serializedReferrer* be an empty string.

3. If *referrer* is a URL, set *serializedReferrer* to the serialization of *referrer*.

4. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	*coop*'s report-only value[p874]
property	*propertyName*
openerURL	If *coopOrigin* and *openerOrigin* are same origin[p870], this is the sanitization[p879] of *openerURL*, null otherwise.
referrer	*serializedReferrer*
type	"access-to-opener"

5. Queue *body* as "coop" for *coop*'s reporting endpoint[p874] with *coopURL*.

To **queue a violation report for access from an opened window**, given a cross-origin opener policy[p874] *coop*, three URLs *coopURL*, *openedWindowURL* and *initialWindowURL*, three origins[p869] *coopOrigin*, *openedWindowOrigin*, and *openerInitialOrigin*, and a string *propertyName*:

1. If *coop*'s reporting endpoint[p874] is null, return.
2. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	*coopValue*
property	*coop*'s report-only value[p874]
openedWindowURL	If *coopOrigin* and *openedWindowOrigin* are same origin[p870], this is the sanitization[p879] of *openedWindowURL*, null otherwise.
openedWindowInitialURL	If *coopOrigin* and *openerInitialOrigin* are same origin[p870], this is the sanitization[p879] of *initialWindowURL*, null otherwise.
type	"access-to-opener"

3. Queue *body* as "coop" for *coop*'s reporting endpoint[p874] with *coopURL*.

To **queue a violation report for access from another window**, given a cross-origin opener policy[p874] *coop*, two URLs *coopURL* and *otherURL*, two origins[p869] *coopOrigin* and *otherOrigin*, and a string *propertyName*:

1. If *coop*'s reporting endpoint[p874] is null, return.
2. Let *body* be a new object containing the following properties:

key	value
disposition	"reporting"
effectivePolicy	*coop*'s report-only value[p874]
property	*propertyName*
otherURL	If *coopOrigin* and *otherOrigin* are same origin[p870], this is the sanitization[p879] of *otherURL*, null otherwise.
type	access-to-opener

3. Queue *body* as "coop" for *coop*'s reporting endpoint[p874] with *coopURL*.

✔ MDN

7.1.4 Cross-origin embedder policies §[p882]

An **embedder policy value** is one of three strings that controls the fetching of cross-origin resources without explicit permission from resource owners.

"unsafe-none"

This is the default value. When this value is used, cross-origin resources can be fetched without giving explicit permission through the CORS protocol or the `Cross-Origin-Resource-Policy` header.

"require-corp"

When this value is used, fetching cross-origin resources requires the server's explicit permission through the CORS protocol or the `Cross-Origin-Resource-Policy` header.

"credentialless"

When this value is used, fetching cross-origin no-CORS resources omits credentials. In exchange, an explicit `Cross-Origin-Resource-Policy` header is not required. Other requests sent with credentials require the server's explicit permission through the CORS protocol or the `Cross-Origin-Resource-Policy` header.

⚠Warning!

Before supporting "credentialless[p882]", implementers are strongly encouraged to support both:

- ***Private Network Access***
- ***Opaque Response Blocking***

Otherwise, it would allow attackers to leverage the client's network position to read non public resources, using the

cross-origin isolated capability[p1032]**.**

An embedder policy value[p882] is **compatible with cross-origin isolation** if it is "`credentialless`[p882]" or "`require-corp`[p882]".

An **embedder policy** consists of:

- A **value**, which is an embedder policy value[p882], initially "`unsafe-none`[p882]".
- A **reporting endpoint** string, initially the empty string.
- A **report only value**, which is an embedder policy value[p882], initially "`unsafe-none`[p882]".
- A **report only reporting endpoint** string, initially the empty string.

The "**`coep`**" **report type** is a report type whose value is "`coep`". It is visible to `ReportingObservers`.

7.1.4.1 The headers §[p883]

The `` `Cross-Origin-Embedder-Policy` `` and `` `Cross-Origin-Embedder-Policy-Report-Only` `` HTTP response headers allow a server to declare an embedder policy[p883] for an environment settings object[p1032]. These headers are structured headers whose values must be token. [STRUCTURED-FIELDS][p1417]

The valid token values are the embedder policy values[p882]. The token may also have attached parameters; of these, the "**`report-to`**" parameter can have a valid URL string identifying an appropriate reporting endpoint. [REPORTING][p1414]

Note

The processing model[p883] fails open (by defaulting to "`unsafe-none`[p882]") in the presence of a header that cannot be parsed as a token. This includes inadvertent lists created by combining multiple instances of the `Cross-Origin-Embedder-Policy`[p883] header present in a given response:

`Cross-Origin-Embedder-Policy`[p883]	*Final embedder policy value*[p882]
No header delivered	"`unsafe-none`[p882]"
`require-corp`	"`require-corp`[p882]"
`unknown-value`	"`unsafe-none`[p882]"
`require-corp, unknown-value`	"`unsafe-none`[p882]"
`unknown-value, unknown-value`	"`unsafe-none`[p882]"
`unknown-value, require-corp`	"`unsafe-none`[p882]"
`require-corp, require-corp`	"`unsafe-none`[p882]"

(The same applies to `Cross-Origin-Embedder-Policy-Report-Only`[p883].)

To **obtain an embedder policy** from a response *response* and an environment[p1031] *environment*:

1. Let *policy* be a new embedder policy[p883].
2. If *environment* is a non-secure context[p1039], then return *policy*.
3. Let *parsedItem* be the result of getting a structured field value with `Cross-Origin-Embedder-Policy`[p883] and "`item`" from *response*'s header list.
4. If *parsedItem* is non-null and *parsedItem*[0] is compatible with cross-origin isolation[p883]:
    1. Set *policy*'s value[p883] to *parsedItem*[0].
    2. If *parsedItem*[1]["`report-to`[p883]"] exists, then set *policy*'s endpoint[p883] to *parsedItem*[1]["`report-to`[p883]"].
5. Set *parsedItem* to the result of getting a structured field value with `Cross-Origin-Embedder-Policy-Report-Only`[p883] and "`item`" from *response*'s header list.

6. If *parsedItem* is non-null and *parsedItem*[0] is compatible with cross-origin isolation[p883]:

    1. Set *policy*'s report only value[p883] to *parsedItem*[0].

    2. If *parsedItem*[1]["`report-to`[p883]"] exists, then set *policy*'s endpoint[p883] to *parsedItem*[1]["`report-to`[p883]"].

7. Return *policy*.

7.1.4.2 Embedder policy checks §[p884]

To **check a navigation response's adherence to its embedder policy** given a response *response*, a navigable[p952] *navigable*, and an embedder policy[p883] *responsePolicy*:

1. If *navigable* is not a child navigable[p955], then return true.

2. Let *parentPolicy* be *navigable*'s container document[p955]'s policy container[p128]'s embedder policy[p888].

3. If *parentPolicy*'s report-only value[p883] is compatible with cross-origin isolation[p883] and *responsePolicy*'s value[p883] is not, then queue a cross-origin embedder policy inheritance violation[p884] with *response*, "`navigation`", *parentPolicy*'s report only reporting endpoint[p883], "`reporting`", and *navigable*'s container document[p955]'s relevant settings object[p1039].

4. If *parentPolicy*'s value[p883] is not compatible with cross-origin isolation[p883] or *responsePolicy*'s value[p883] is compatible with cross-origin isolation[p883], then return true.

5. Queue a cross-origin embedder policy inheritance violation[p884] with *response*, "`navigation`", *parentPolicy*'s reporting endpoint[p883], "`enforce`", and *navigable*'s container document[p955]'s relevant settings object[p1039].

6. Return false.

To **check a global object's embedder policy** given a `WorkerGlobalScope`[p1166] *workerGlobalScope*, an environment settings object[p1032] *owner*, and a response *response*:

1. If *workerGlobalScope* is not a `DedicatedWorkerGlobalScope`[p1168] object, then return true.

2. Let *policy* be *workerGlobalScope*'s embedder policy[p1167].

3. Let *ownerPolicy* be *owner*'s policy container[p1032]'s embedder policy[p888].

4. If *ownerPolicy*'s report-only value[p883] is compatible with cross-origin isolation[p883] and *policy*'s value[p883] is not, then queue a cross-origin embedder policy inheritance violation[p884] with *response*, "`worker initialization`", *owner's policy*'s report only reporting endpoint[p883], "`reporting`", and *owner*.

5. If *ownerPolicy*'s value[p883] is not compatible with cross-origin isolation[p883] or *policy*'s value[p883] is compatible with cross-origin isolation[p883], then return true.

6. Queue a cross-origin embedder policy inheritance violation[p884] with *response*, "`worker initialization`", *owner's policy*'s reporting endpoint[p883], "`enforce`", and *owner*.

7. Return false.

To **queue a cross-origin embedder policy inheritance violation** given a response *response*, a string *type*, a string *endpoint*, a string *disposition*, and an environment settings object[p1032] *settings*:

1. Let *serialized* be the result of serializing a response URL for reporting with *response*.

2. Let *body* be a new object containing the following properties:

key	value
type	*type*
blockedURL	*serialized*
disposition	*disposition*

3. Queue *body* as the "`coep`" report type[p883] for *endpoint* on *settings*.

7.1.5 Sandboxing §[p885]

A **sandboxing flag set** is a set of zero or more of the following flags, which are used to restrict the abilities that potentially untrusted resources have:

The *sandboxed navigation browsing context flag*

This flag prevents content from navigating browsing contexts other than the sandboxed browsing context itself[p977] (or browsing contexts further nested inside it), auxiliary browsing contexts[p961] (which are protected by the sandboxed auxiliary navigation browsing context flag[p885] defined next), and the top-level browsing context[p964] (which is protected by the sandboxed top-level navigation without user activation browsing context flag[p885] and sandboxed top-level navigation with user activation browsing context flag[p885] defined below).

If the sandboxed auxiliary navigation browsing context flag[p885] is not set, then in certain cases the restrictions nonetheless allow popups (new top-level browsing contexts[p964]) to be opened. These browsing contexts[p961] always have **one permitted sandboxed navigator**, set when the browsing context is created, which allows the browsing context[p961] that created them to actually navigate them. (Otherwise, the sandboxed navigation browsing context flag[p885] would prevent them from being navigated even if they were opened.)

The *sandboxed auxiliary navigation browsing context flag*

This flag prevents content from creating new auxiliary browsing contexts[p960], e.g. using the `target`[p297] attribute or the `window.open()`[p896] method.

The *sandboxed top-level navigation without user activation browsing context flag*

This flag prevents content from navigating their top-level browsing context[p977] and prevents content from closing their top-level browsing context[p898]. It is consulted only when the sandboxed browsing context's active window[p961] does not have transient activation[p811].

When the sandboxed top-level navigation without user activation browsing context flag[p885] is *not* set, content can navigate its top-level browsing context[p964], but other browsing contexts[p961] are still protected by the sandboxed navigation browsing context flag[p885] and possibly the sandboxed auxiliary navigation browsing context flag[p885].

The *sandboxed top-level navigation with user activation browsing context flag*

This flag prevents content from navigating their top-level browsing context[p977] and prevents content from closing their top-level browsing context[p898]. It is consulted only when the sandboxed browsing context's active window[p961] has transient activation[p811].

As with the sandboxed top-level navigation without user activation browsing context flag[p885], this flag only affects the top-level browsing context[p964]; if it is not set, other browsing contexts[p961] might still be protected by other flags.

The *sandboxed origin browsing context flag*

This flag forces content into a unique origin[p964], thus preventing it from accessing other content from the same origin[p869].

This flag also prevents script from reading from or writing to the `document.cookie` IDL attribute[p129], and blocks access to `localStorage`[p1194].

The *sandboxed forms browsing context flag*

This flag blocks form submission[p619].

The *sandboxed pointer lock browsing context flag*

This flag disables the Pointer Lock API. [POINTERLOCK][p1415]

The *sandboxed scripts browsing context flag*

This flag blocks script execution[p1039].

The *sandboxed automatic features browsing context flag*

This flag blocks features that trigger automatically, such as automatically playing a video[p427] or automatically focusing a form control[p828].

The *sandboxed* `document.domain` *browsing context flag*

This flag prevents content from using the `document.domain`[p872] setter.

The *sandbox propagates to auxiliary browsing contexts flag*

This flag prevents content from escaping the sandbox by ensuring that any auxiliary browsing context[p961] it creates inherits the content's active sandboxing flag set[p887].

The *sandboxed modals flag*

This flag prevents content from using any of the following features to produce modal dialogs:

- `window.alert()`[p1106]
- `window.confirm()`[p1107]
- `window.print()`[p1108]
- `window.prompt()`[p1107]
- the `beforeunload`[p1406] event

The *sandboxed orientation lock browsing context flag*

This flag disables the ability to lock the screen orientation. [SCREENORIENTATION][p1416]

The *sandboxed presentation browsing context flag*

This flag disables the Presentation API. [PRESENTATION][p1415]

The *sandboxed downloads browsing context flag*

This flag prevents content from initiating or instantiating downloads, whether through downloading hyperlinks[p304] or through navigation[p993] that gets handled as a download[p305].

The *sandboxed custom protocols navigation browsing context flag*

This flag prevents navigations toward non fetch schemes from being handed off to external software[p986].

When the user agent is to **parse a sandboxing directive**, given a string *input*, a sandboxing flag set[p885] *output*, it must run the following steps:

1. Split *input* on ASCII whitespace, to obtain *tokens*.
2. Let *output* be empty.
3. Add the following flags to *output*:
   - The sandboxed navigation browsing context flag[p885].
   - The sandboxed auxiliary navigation browsing context flag[p885], unless *tokens* contains the **`allow-popups`** keyword.
   - The sandboxed top-level navigation without user activation browsing context flag[p885], unless *tokens* contains the **`allow-top-navigation`** keyword.
   - The sandboxed top-level navigation with user activation browsing context flag[p885], unless *tokens* contains either the **`allow-top-navigation-by-user-activation`** keyword or the `allow-top-navigation`[p886] keyword.

     Note

     This means that if the `allow-top-navigation`[p886] is present, the `allow-top-navigation-by-user-activation`[p886] keyword will have no effect. For this reason, specifying both is a document conformance error.

   - The sandboxed origin browsing context flag[p885], unless the *tokens* contains the **`allow-same-origin`** keyword.

     Note

     The `allow-same-origin`[p886] keyword is intended for two cases.

     First, it can be used to allow content from the same site to be sandboxed to disable scripting, while still allowing access to the DOM of the sandboxed content.

     Second, it can be used to embed content from a third-party site, sandboxed to prevent that site from opening popups, etc, without preventing the embedded page from communicating back to its originating site, using the database APIs to store data, etc.

   - The sandboxed forms browsing context flag[p885], unless *tokens* contains the **`allow-forms`** keyword.
   - The sandboxed pointer lock browsing context flag[p885], unless *tokens* contains the **`allow-pointer-lock`** keyword.
   - The sandboxed scripts browsing context flag[p885], unless *tokens* contains the **`allow-scripts`** keyword.

- The sandboxed automatic features browsing context flag[p885], unless *tokens* contains the `allow-scripts`[p886] keyword (defined above).

  Note

  This flag is relaxed by the same keyword as scripts, because when scripts are enabled these features are trivially possible anyway, and it would be unfortunate to force authors to use script to do them when sandboxed rather than allowing them to use the declarative features.

- The sandboxed `document.domain` browsing context flag[p885].
- The sandbox propagates to auxiliary browsing contexts flag[p885], unless *tokens* contains the **`allow-popups-to-escape-sandbox`** keyword.
- The sandboxed modals flag[p886], unless *tokens* contains the **`allow-modals`** keyword.
- The sandboxed orientation lock browsing context flag[p886], unless *tokens* contains the **`allow-orientation-lock`** keyword.
- The sandboxed presentation browsing context flag[p886], unless *tokens* contains the **`allow-presentation`** keyword.
- The sandboxed downloads browsing context flag[p886], unless *tokens* contains the **`allow-downloads`** keyword.
- The sandboxed custom protocols navigation browsing context flag[p886], unless *tokens* contains either the **`allow-top-navigation-to-custom-protocols`** keyword, the `allow-popups`[p886] keyword, or the `allow-top-navigation`[p886] keyword.

Every top-level browsing context[p964] has a **popup sandboxing flag set**, which is a sandboxing flag set[p885]. When a browsing context[p961] is created, its popup sandboxing flag set[p887] must be empty. It is populated by the rules for choosing a navigable[p959] and the obtain a browsing context to use for a navigation response[p877] algorithm.

Every `iframe`[p383] element has an **`iframe` sandboxing flag set**, which is a sandboxing flag set[p885]. Which flags in an `iframe` sandboxing flag set[p887] are set at any particular time is determined by the `iframe`[p383] element's `sandbox`[p388] attribute.

Every `Document`[p127] has an **active sandboxing flag set**, which is a sandboxing flag set[p885]. When the `Document`[p127] is created, its active sandboxing flag set[p887] must be empty. It is populated by the navigation algorithm[p977].

Every CSP list *cspList* has **CSP-derived sandboxing flags**, which is a sandboxing flag set[p885]. It is the return value of the following algorithm:

1. Let *directives* be an empty ordered set.
2. For each policy in *cspList*:
   1. If *policy*'s disposition is not "`enforce`", then continue.
   2. If *policy*'s directive set contains a directive whose name is "`sandbox`", then append that directive to *directives*.
3. If *directives* is empty, then return an empty sandboxing flag set[p885].
4. Let *directive* be *directives*[*directives*'s size − 1].
5. Return the result of parsing the sandboxing directive[p886] *directive*.

To **determine the creation sandboxing flags** for a browsing context[p961] *browsing context*, given null or an element *embedder*, return the union of the flags that are present in the following sandboxing flag sets[p885]:

- If *embedder* is null, then: the flags set on *browsing context*'s popup sandboxing flag set[p887].
- If *embedder* is an element, then: the flags set on *embedder*'s `iframe` sandboxing flag set[p887].
- If *embedder* is an element, then: the flags set on *embedder*'s node document's active sandboxing flag set[p887].

7.1.6 Policy containers §[p888]

A **policy container** is a struct containing policies that apply to a `Document`[p127], a `WorkerGlobalScope`[p1166], or a `WorkletGlobalScope`[p1184]. It has the following items:

- A **CSP list**, which is a CSP list. It is initially empty.
- An **embedder policy**, which is an embedder policy[p883]. It is initially a new embedder policy[p883].
- A **referrer policy**, which is a referrer policy. It is initially the default referrer policy.

Move other policies into the policy container.

To **clone a policy container** given a policy container[p888] *policyContainer*:

1. Let *clone* be a new policy container[p888].
2. For each *policy* in *policyContainer*'s CSP list[p888], append a copy of *policy* into *clone*'s CSP list[p888].
3. Set *clone*'s embedder policy[p888] to a copy of *policyContainer*'s embedder policy[p888].
4. Set *clone*'s referrer policy[p888] to *policyContainer*'s referrer policy[p888].
5. Return *clone*.

To determine whether a URL *url* **requires storing the policy container in history**:

1. If *url*'s scheme is "`blob`", then return false.
2. If *url* is local, then return true.
3. Return false.

To **create a policy container from a fetch response** given a response *response* and an environment[p1031]-or-null *environment*:

1. If *response*'s URL's scheme is "`blob`", then return a clone[p888] of *response*'s URL's blob URL entry's environment's policy container[p888].
2. Let *result* be a new policy container[p888].
3. Set *result*'s CSP list[p888] to the result of parsing a response's Content Security Policies given *response*.
4. If *environment* is non-null, then set *result*'s embedder policy[p888] to the result of obtaining an embedder policy[p883] given *response* and *environment*. Otherwise, set it to "`unsafe-none`[p882]".
5. Set *result*'s referrer policy[p888] to the result of parsing the `Referrer-Policy` header given *response*. [REFERRERPOLICY][p1416]
6. Return *result*.

To **determine navigation params policy container** given a URL *responseURL* and four policy container[p888]-or-nulls *historyPolicyContainer*, *initiatorPolicyContainer*, *parentPolicyContainer*, and *responsePolicyContainer*:

1. If *historyPolicyContainer* is not null, then:
    1. Assert: *responseURL* requires storing the policy container in history[p888].
    2. Return a clone[p888] of *historyPolicyContainer*.
2. If *responseURL* is `about:srcdoc`[p94], then:
    1. Assert: *parentPolicyContainer* is not null.
    2. Return a clone[p888] of *parentPolicyContainer*.
3. If *responseURL* is local and *initiatorPolicyContainer* is not null, then return a clone[p888] of *initiatorPolicyContainer*.
4. If *responsePolicyContainer* is not null, then return *responsePolicyContainer*.
5. Return a new policy container[p888].

To **initialize a worker global scope's policy container** given a WorkerGlobalScope[p1166] *workerGlobalScope*, a response *response*, and an environment[p1031] *environment*:

1. If *workerGlobalScope*'s url[p1167] is local but its scheme is not "blob":
    1. Assert: *workerGlobalScope*'s owner set[p1166]'s size is 1.
    2. Set *workerGlobalScope*'s policy container[p1167] to a clone[p888] of *workerGlobalScope*'s owner set[p1166][0]'s relevant settings object[p1039]'s policy container[p1032].
2. Otherwise, set *workerGlobalScope*'s policy container[p1167] to the result of creating a policy container from a fetch response[p888] given *response* and *environment*.

7.2 APIs related to navigation and session history §[p889]

7.2.1 Security infrastructure for Window[p892], WindowProxy[p904], and Location[p908] objects §[p889]

Although typically objects cannot be accessed across origins[p869], the web platform would not be true to itself if it did not have some legacy exceptions to that rule that the web depends upon.

This section uses the terminology and typographic conventions from the JavaScript specification. [JAVASCRIPT][p1414]

7.2.1.1 Integration with IDL §[p889]

When perform a security check is invoked, with a *platformObject*, *identifier*, and *type*, run these steps:

1. If *platformObject* is not a Window[p892] or Location[p908] object, then return.
2. For each *e* of CrossOriginProperties[p890](*platformObject*):
    1. If SameValue(*e*.[[Property]], *identifier*) is true, then:
        1. If *type* is "method" and *e* has neither [[NeedsGet]] nor [[NeedsSet]], then return.
        2. Otherwise, if *type* is "getter" and *e*.[[NeedsGet]] is true, then return.
        3. Otherwise, if *type* is "setter" and *e*.[[NeedsSet]] is true, then return.
3. If IsPlatformObjectSameOrigin[p890](*platformObject*) is false, then throw a "SecurityError" DOMException.

7.2.1.2 Shared internal slot: [[CrossOriginPropertyDescriptorMap]] §[p889]

Window[p892] and Location[p908] objects both have a **[[CrossOriginPropertyDescriptorMap]]** internal slot, whose value is initially an empty map.

The [[CrossOriginPropertyDescriptorMap]][p889] internal slot contains a map with entries whose keys are (*currentGlobal*, *objectGlobal*, *propertyKey*)-tuples and values are property descriptors, as a memoization of what is visible to scripts when *currentGlobal* inspects a Window[p892] or Location[p908] object from *objectGlobal*. It is filled lazily by CrossOriginGetOwnPropertyHelper[p891], which consults it on future lookups.

User agents should allow a value held in the map to be garbage collected along with its corresponding key when nothing holds a reference to any part of the value. That is, as long as garbage collection is not observable.

Example

For example, with `const href = Object.getOwnPropertyDescriptor(crossOriginLocation, "href").set` the value and its corresponding key in the map cannot be garbage collected as that would be observable.

User agents may have an optimization whereby they remove key-value pairs from the map when document.domain[p872] is set. This is not observable as document.domain[p872] cannot revisit an earlier value.

Example

For example, setting document.domain[p872] to "example.com" on www.example.com means user agents can remove all key-value pairs from the map where part of the key is www.example.com, as that can never be part of the origin[p869] again and therefore the corresponding value could never be retrieved from the map.

7.2.1.3 Shared abstract operations §[p89]

7.2.1.3.1 CrossOriginProperties (O) §[p89]

1. Assert: *O* is a Location[p908] or Window[p892] object.

2. If *O* is a Location[p908] object, then return « { [[Property]]: "href", [[NeedsGet]]: false, [[NeedsSet]]: true }, { [[Property]]: "replace" } ».

3. Return « { [[Property]]: "window", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "self", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "location", [[NeedsGet]]: true, [[NeedsSet]]: true }, { [[Property]]: "close" }, { [[Property]]: "closed", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "focus" }, { [[Property]]: "blur" }, { [[Property]]: "frames", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "length", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "top", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "opener", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "parent", [[NeedsGet]]: true, [[NeedsSet]]: false }, { [[Property]]: "postMessage" } ».

Note

This abstract operation does not return a Completion Record.

Note

Indexed properties do not need to be safelisted in this algorithm, as they are handled directly by the WindowProxy[p904] object.

A JavaScript property name *P* is a **cross-origin accessible window property name** if it is "window", "self", "location", "close", "closed", "focus", "blur", "frames", "length", "top", "opener", "parent", "postMessage", or an array index property name.

7.2.1.3.2 CrossOriginPropertyFallback (P) §[p89]

1. If *P* is "then", @@toStringTag[p56], @@hasInstance[p56], or @@isConcatSpreadable[p56], then return PropertyDescriptor{ [[Value]]: undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: true }.

2. Throw a "SecurityError" DOMException.

7.2.1.3.3 IsPlatformObjectSameOrigin (O) §[p89]

1. Return true if the current settings object[p1038]'s origin[p1032] is same origin-domain[p870] with *O*'s relevant settings object[p1039]'s origin[p1032], and false otherwise.

Note

This abstract operation does not return a Completion Record.

Note

Here the current settings object[p1038] roughly corresponds to the "caller", because this check occurs before the execution context for the getter/setter/method in question makes its way onto the JavaScript execution context stack. For example, in the code w.document*, this step is invoked before the* document[p894] *getter is reached as part of the [[Get]][p906] algorithm for the* WindowProxy[p904] w*.*

7.2.1.3.4 CrossOriginGetOwnPropertyHelper (O, P) §[p891]

Note

If this abstract operation returns undefined and there is no custom behavior, the caller needs to throw a "SecurityError" DOMException. In practice this is handled by the caller calling CrossOriginPropertyFallback[p890].

1. Let *crossOriginKey* be a tuple consisting of the current settings object[p1038], *O*'s relevant settings object[p1039], and *P*.
2. For each *e* of CrossOriginProperties[p890](*O*):
    1. If SameValue(*e*.[[Property]], *P*) is true, then:
        1. If the value of the [[CrossOriginPropertyDescriptorMap]][p889] internal slot of *O* contains an entry whose key is *crossOriginKey*, then return that entry's value.
        2. Let *originalDesc* be OrdinaryGetOwnProperty(*O*, *P*).
        3. Let *crossOriginDesc* be undefined.
        4. If *e*.[[NeedsGet]] and *e*.[[NeedsSet]] are absent, then:
            1. Let *value* be *originalDesc*.[[Value]].
            2. If IsCallable(*value*) is true, then set *value* to an anonymous built-in function, created in the current realm, that performs the same steps as the IDL operation *P* on object *O*.
            3. Set *crossOriginDesc* to PropertyDescriptor{ [[Value]]: *value*, [[Enumerable]]: false, [[Writable]]: false, [[Configurable]]: true }.
        5. Otherwise:
            1. Let *crossOriginGet* be undefined.
            2. If *e*.[[NeedsGet]] is true, then set *crossOriginGet* to an anonymous built-in function, created in the current realm, that performs the same steps as the getter of the IDL attribute *P* on object *O*.
            3. Let *crossOriginSet* be undefined.
            4. If *e*.[[NeedsSet]] is true, then set *crossOriginSet* to an anonymous built-in function, created in the current realm, that performs the same steps as the setter of the IDL attribute *P* on object *O*.
            5. Set *crossOriginDesc* to PropertyDescriptor{ [[Get]]: *crossOriginGet*, [[Set]]: *crossOriginSet*, [[Enumerable]]: false, [[Configurable]]: true }.
        6. Create an entry in the value of the [[CrossOriginPropertyDescriptorMap]][p889] internal slot of *O* with key *crossOriginKey* and value *crossOriginDesc*.
        7. Return *crossOriginDesc*.
3. Return undefined.

Note

This abstract operation does not return a Completion Record.

Note

The reason that the property descriptors produced here are configurable is to preserve the invariants of the essential internal methods required by the JavaScript specification. In particular, since the value of the property can change as a consequence of navigation, it is required that the property be configurable. (However, see tc39/ecma262 issue #672 and references to it elsewhere in this specification for cases where we are not able to preserve these invariants, for compatibility with existing web content.) [JAVASCRIPT][p1414]

Note

The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing web content. See issue #3183 for details.

7.2.1.3.5 CrossOriginGet (O, P, Receiver) §p89 2

1. Let *desc* be ? *O*.[[GetOwnProperty]](*P*).
2. Assert: *desc* is not undefined.
3. If IsDataDescriptor(*desc*) is true, then return *desc*.[[Value]].
4. Assert: IsAccessorDescriptor(*desc*) is true.
5. Let *getter* be *desc*.[[Get]].
6. If *getter* is undefined, then throw a "SecurityError" DOMException.
7. Return ? Call(*getter*, *Receiver*).

7.2.1.3.6 CrossOriginSet (O, P, V, Receiver) §p89 2

1. Let *desc* be ? *O*.[[GetOwnProperty]](*P*).
2. Assert: *desc* is not undefined.
3. If *desc*.[[Set]] is present and its value is not undefined, then:
    1. Perform ? Call(*setter*, *Receiver*, «*V*»).
    2. Return true.
4. Throw a "SecurityError" DOMException.

7.2.1.3.7 CrossOriginOwnPropertyKeys (O) §p89 2

1. Let *keys* be a new empty List.
2. For each *e* of CrossOriginProperties p890 (*O*), append *e*.[[Property]] to *keys*.
3. Return the concatenation of *keys* and « "then", @@toStringTag p56, @@hasInstance p56, @@isConcatSpreadable p56 ».

Note

This abstract operation does not return a Completion Record.

7.2.2 The Window p892 object §p89 2

MDN

```
IDL
[Global=Window,
 Exposed=Window,
 LegacyUnenumerableNamedProperties]
interface Window : EventTarget {
  // the current browsing context
  [LegacyUnforgeable] readonly attribute WindowProxy window;
  [Replaceable] readonly attribute WindowProxy self;
  [LegacyUnforgeable] readonly attribute Document document;
  attribute DOMString name;
  [PutForwards=href, LegacyUnforgeable] readonly attribute Location location;
  readonly attribute History history;
  readonly attribute Navigation navigation;
  readonly attribute CustomElementRegistry customElements;
  [Replaceable] readonly attribute BarProp locationbar;
  [Replaceable] readonly attribute BarProp menubar;
```

```
  [Replaceable] readonly attribute BarProp personalbar;
  [Replaceable] readonly attribute BarProp scrollbars;
  [Replaceable] readonly attribute BarProp statusbar;
  [Replaceable] readonly attribute BarProp toolbar;
  attribute DOMString status;
  undefined close();
  readonly attribute boolean closed;
  undefined stop();
  undefined focus();
  undefined blur();

  // other browsing contexts
  [Replaceable] readonly attribute WindowProxy frames;
  [Replaceable] readonly attribute unsigned long length;
  [LegacyUnforgeable] readonly attribute WindowProxy? top;
  attribute any opener;
  [Replaceable] readonly attribute WindowProxy? parent;
  readonly attribute Element? frameElement;
  WindowProxy? open(optional USVString url = "", optional DOMString target = "_blank", optional
[LegacyNullToEmptyString] DOMString features = "");

  // Since this is the global object, the IDL named getter adds a NamedPropertiesObject exotic
  // object on the prototype chain. Indeed, this does not make the global object an exotic object.
  // Indexed access is taken care of by the WindowProxy exotic object.
  getter object (DOMString name);

  // the user agent
  readonly attribute Navigator navigator;
  readonly attribute Navigator clientInformation; // legacy alias of .navigator
  readonly attribute boolean originAgentCluster;

  // user prompts
  undefined alert();
  undefined alert(DOMString message);
  boolean confirm(optional DOMString message = "");
  DOMString? prompt(optional DOMString message = "", optional DOMString default = "");
  undefined print();

  undefined postMessage(any message, USVString targetOrigin, optional sequence<object> transfer = []);
  undefined postMessage(any message, optional WindowPostMessageOptions options = {});

  // also has obsolete members
};
Window includes GlobalEventHandlers;
Window includes WindowEventHandlers;

dictionary WindowPostMessageOptions : StructuredSerializeOptions {
  USVString targetOrigin = "/";
};
```

For web developers (non-normative)

***window*.window**[p894]

***window*.frames**[p894]

***window*.self**[p894]

These attributes all return *window*.

***window*.document**[p894]

Returns the Document[p127] associated with *window*.

***document*.defaultView**[p894]

Returns the Window[p892] associated with *document*, if there is one, or null otherwise.

The Window[p892] object has an **associated Document**, which is a Document[p127] object. It is set when the Window[p892] object is created, and only ever changed during navigation[p977] from the initial about:blank[p128] Document[p127].

A Window[p892]'s **browsing context** is its associated Document[p894]'s browsing context[p961]. Note *It is either null or a browsing context[p961].*

A Window[p892]'s **navigable** is the navigable[p952] whose active document[p952] is the Window[p892]'s associated Document[p894]'s, or null if there is no such navigable[p952].

The **window**, **frames**, and **self** getter steps are to return this's relevant realm[p1039].[[GlobalEnv]].[[GlobalThisValue]].

The **document** getter steps are to return this's associated Document[p894].

Note

The Document[p127] object associated with a Window[p892] object can change in exactly one case: when the navigate[p977] algorithm creates a new Document object[p1013] for the first page loaded in a browsing context[p961]. In that specific case, the Window[p892] object of the initial about:blank[p128] page is reused and gets a new Document[p127] object.

The **defaultView** getter steps are:

1. If this's browsing context[p961] is null, then return null.
2. Return this's browsing context[p961]'s WindowProxy[p904] object.

For historical reasons, Window[p892] objects must also have a writable, configurable, non-enumerable property named **HTMLDocument** MDN whose value is the Document[p127] interface object.

7.2.2.1 Opening and closing windows §[p894]

For web developers (non-normative)

***window* = *window*.open[p896]([*url* [, *target* [, *features*]]])**

Opens a window to show *url* (defaults to "about:blank[p53]"), and returns it. *target* (defaults to "_blank") gives the name of the new window. If a window already exists with that name, it is reused. The *features* argument can contain a set of comma-separated tokens[p93]:

"noopener"

"noreferrer"

These behave equivalently to the noopener[p318] and noreferrer[p318] link types on hyperlinks[p297].

"popup"

Encourages user agents to provide a minimal web browser user interface for the new window. (Impacts the visible[p902] getter on all BarProp[p902] objects as well.)

Example

```
globalThis.open("https://email.example/message/
CAOOOkFcWW97r8yg=SsWg7GgCmp4suVX9o85y8BvNRqMjuc5PXg", undefined, "noopener,popup");
```

***window*.name[p898] [= *value*]**

Returns the name of the window.

Can be set, to change the name.

***window*.close[p898]()**

Closes the window.

***window*.closed**[p898]

Returns true if the window has been closed, false otherwise.

***window*.stop**[p898]**()**

Cancels the document load.

The **window open steps**, given a string *url*, a string *target*, and a string *features*, are as follows:

1. If the event loop[p1071]'s termination nesting level[p1021] is nonzero, return null.
2. Let *sourceDocument* be the entry global object[p1035]'s associated `Document`[p894].
3. If *target* is the empty string, then set *target* to "`_blank`".
4. Let *tokenizedFeatures* be the result of tokenizing[p896] *features*.
5. Let *noopener* and *noreferrer* be false.
6. If *tokenizedFeatures*["`noopener`"] exists, then:
    1. Set *noopener* to the result of parsing *tokenizedFeatures*["`noopener`"] as a boolean feature[p897].
    2. Remove *tokenizedFeatures*["`noopener`"].
7. If *tokenizedFeatures*["`noreferrer`"] exists, then:
    1. Set *noreferrer* to the result of parsing *tokenizedFeatures*["`noreferrer`"] as a boolean feature[p897].
    2. Remove *tokenizedFeatures*["`noreferrer`"].
8. Let *referrerPolicy* be the empty string.
9. If *noreferrer* is true, then set *noopener* to true and set *referrerPolicy* to "`no-referrer`".
10. Let *targetNavigable* and *windowType* be the result of applying the rules for choosing a navigable[p959] given *target*, *sourceDocument*'s node navigable[p953], and *noopener*.

    Example

    If there is a user agent that supports control-clicking a link to open it in a new tab, and the user control-clicks on an element whose `onclick`[p1090] handler uses the `window.open()`[p896] API to open a page in an `iframe`[p383] element, the user agent could override the selection of the target browsing context to instead target a new tab.

11. If *targetNavigable* is null, then return null.
12. If *windowType* is either "`new and unrestricted`" or "`new with no opener`", then:
    1. Set *targetNavigable*'s active browsing context[p952]'s is popup[p961] to the result of checking if a popup window is requested[p897], given *tokenizedFeatures*.
    2. Set up browsing context features for *targetNavigable*'s active browsing context[p952] given *tokenizedFeatures*.[CSSOMVIEW][p1412]
    3. Let *urlRecord* be the URL record `about:blank`[p53].
    4. If *url* is not the empty string, then parse[p95] *url* relative to the entry settings object[p1035], and set *urlRecord* to the resulting URL record[p95], if any. If the parse a URL[p95] algorithm failed, then throw a "`SyntaxError`" `DOMException`.
    5. If *urlRecord* matches `about:blank`[p94], then perform the URL and history update steps[p991] given *targetNavigable*'s active document[p952] and *urlRecord*.

        Note

        This is necessary in case url *is something like* `about:blank?foo`*. If* url *is just plain* `about:blank`*, this will do nothing.*

    6. Otherwise, navigate[p977] *targetNavigable* to *urlRecord* using *sourceDocument*, with *referrerPolicy*[p977] set to *referrerPolicy* and *exceptionsEnabled*[p977] set to true.

13. Otherwise:
    1. If *url* is not the empty string, then:
        1. Let *urlRecord* be the URL record `about:blank`[p53].
        2. Parse[p95] *url* relative to the entry settings object[p1035], and set *urlRecord* to the resulting URL record[p95], if any. If the parse a URL[p95] algorithm failed, then throw a `"SyntaxError"` `DOMException`.
        3. Navigate[p977] *targetNavigable* to *urlRecord* using *sourceDocument*, with *referrerPolicy*[p977] set to *referrerPolicy* and *exceptionsEnabled*[p977] set to true.
    2. If *noopener* is false, then set *targetNavigable*'s active browsing context[p952]'s opener browsing context[p961] to *sourceDocument*'s browsing context[p961].
14. If *noopener* is true or *windowType* is "`new with no opener`", then return null.
15. Return *targetNavigable*'s active `WindowProxy`[p952].

The **`open(url, target, features)`** method steps are to run the window open steps[p895] with *url*, *target*, and *features*.

> **Note**
> *The method provides a mechanism for navigating[p977] an existing browsing context[p961] or opening and navigating an auxiliary browsing context[p961].*

To **tokenize the *features* argument**:

1. Let *tokenizedFeatures* be a new ordered map.
2. Let *position* point at the first code point of *features*.
3. While *position* is not past the end of *features*:
    1. Let *name* be the empty string.
    2. Let *value* be the empty string.
    3. Collect a sequence of code points that are feature separators[p897] from *features* given *position*. This skips past leading separators before the name.
    4. Collect a sequence of code points that are not feature separators[p897] from *features* given *position*. Set *name* to the collected characters, converted to ASCII lowercase.
    5. Set *name* to the result of normalizing the feature name[p897] *name*.
    6. While *position* is not past the end of *features* and the code point at *position* in *features* is not U+003D (=):
        1. If the code point at *position* in *features* is U+002C (,), or if it is not a feature separator[p897], then break.
        2. Advance *position* by 1.

        > **Note**
        > *This skips to the first U+003D (=) but does not skip past a U+002C (,) or a non-separator.*

    7. If the code point at *position* in *features* is a feature separator[p897]:
        1. While *position* is not past the end of *features* and the code point at *position* in *features* is a feature separator[p897]:
            1. If the code point at *position* in *features* is U+002C (,), then break.
            2. Advance *position* by 1.

            > **Note**
            > *This skips to the first non-separator but does not skip past a U+002C (,).*

        2. Collect a sequence of code points that are not feature separators[p897] code points from *features* given

position. Set *value* to the collected code points, converted to ASCII lowercase.

8. If *name* is not the empty string, then set *tokenizedFeatures*[*name*] to *value*.

4. Return *tokenizedFeatures*.

To **check if a window feature is set**, given *tokenizedFeatures*, *featureName*, and *defaultValue*:

1. If *tokenizedFeatures*[*featureName*] exists, then return the result of parsing *tokenizedFeatures*[*featureName*] as a boolean feature[p897].

2. Return *defaultValue*.

To **check if a popup window is requested**, given *tokenizedFeatures*:

1. If *tokenizedFeatures* is empty, then return false.

2. If *tokenizedFeatures*["`popup`"] exists, then return the result of parsing *tokenizedFeatures*["`popup`"] as a boolean feature[p897].

3. Let *location* be the result of checking if a window feature is set[p897], given *tokenizedFeatures*, "`location`", and false.

4. Let *toolbar* be the result of checking if a window feature is set[p897], given *tokenizedFeatures*, "`toolbar`", and false.

5. If *location* and *toolbar* are both false, then return true.

6. Let *menubar* be the result of checking if a window feature is set[p897], given *tokenizedFeatures*, `menubar`", and false.

7. If *menubar* is false, then return true.

8. Let *resizable* be the result of checking if a window feature is set[p897], given *tokenizedFeatures*, "`resizable`", and true.

9. If *resizable* is false, then return true.

10. Let *scrollbars* be the result of checking if a window feature is set[p897], given *tokenizedFeatures*, "`scrollbars`", and false.

11. If *scrollbars* is false, then return true.

12. Let *status* be the result of checking if a window feature is set[p897], given *tokenizedFeatures*, "`status`", and false.

13. If *status* is false, then return true.

14. Return false.

A code point is a **feature separator** if it is ASCII whitespace, U+003D (=), or U+002C (,).

For legacy reasons, there are some aliases of some feature names. To **normalize a feature name** *name*, switch on *name*:

↪ **"`screenx`"**
Return "`left`".

↪ **"`screeny`"**
Return "`top`".

↪ **"`innerwidth`"**
Return "`width`".

↪ **"`innerheight`"**
Return "`height`".

↪ **Anything else**
Return *name*.

To **parse a boolean feature** given a string *value*:

1. If *value* is the empty string, then return true.

2. If *value* is "`yes`", then return true.

3. If *value* is "`true`", then return true.

4. Let *parsed* be the result of parsing *value* as an integer[p74].

5. If *parsed* is an error, then set it to 0.
6. Return false if *parsed* is 0, and true otherwise.

The **name** getter steps are:

1. If this's navigable[p894] is null, then return the empty string.
2. Return this's navigable[p894]'s target name[p953].

The name[p898] setter steps are:

1. If this's navigable[p894] is null, then return.
2. Set this's navigable[p894]'s active session history entry[p952]'s document state[p968]'s navigable target name[p970] to the given value.

Note

The name gets reset[p981] when the navigable is navigated[p977] to another origin[p869].

The **close()** method steps are:

1. Let *thisTraversable* be null.
2. For each top-level traversable[p953] *traversable* of the user agent's top-level traversable set[p954]: if *traversable*'s active document[p952]'s relevant global object[p1039] equals this, then set *thisTraversable* to *traversable* and break.
3. If *thisTraversable* is null, then return.

   Note

   In this case the method is being called on a Window[p892] that does not correspond to a top-level traversable[p953], and so closing is not allowed.

4. If *thisTraversable*'s is closing[p952] is true, then return.
5. Let *browsingContext* be *thisTraversable*'s active browsing context[p952].
6. Let *sourceSnapshotParams* be the result of snapshotting source snapshot params[p975] given *thisTraversable*'s active document[p952].
7. If all the following are true:

   - *thisTraversable* is script-closable[p898];
   - the incumbent global object[p1036]'s browsing context[p894] is familiar with[p964] *browsingContext*; and
   - the incumbent global object[p1036]'s node navigable[p953] is allowed by sandboxing to navigate[p987] *thisTraversable*, given *sourceSnapshotParams*

   then:

   1. Set *thisTraversable*'s is closing[p952] to true.
   2. Queue a task[p1072] on the DOM manipulation task source[p1080] to close[p958] *thisTraversable*.

A navigable[p952] is **script-closable** if its active browsing context[p952] is an auxiliary browsing context[p961] that was created by a script (as opposed to by an action of the user), or if it is a top-level traversable[p953] whose session history entries[p953]'s size is 1.

The **closed** getter steps are to return true if this's browsing context[p894] is null or its is closing[p952] is true; otherwise false.

The **stop()** method steps are:

1. If this's navigable[p894] is null, then return.
2. Stop loading[p1024] this's navigable[p894].

7.2.2.2 Indexed access on the Window[p892] object §[p899]

For web developers (non-normative)

***window*.length**[p899]

Returns the number of document-tree child navigables[p958].

***window*[*index*]**

Returns the WindowProxy[p904] corresponding to the indicated document-tree child navigables[p958].

The **length** getter steps are to return this's associated Document[p894]'s document-tree child navigables[p958]'s size.

Note

Indexed access to document-tree child navigables[p958] is defined through the [[GetOwnProperty]][p905] internal method of the WindowProxy[p904] object.

7.2.2.3 Named access on the Window[p892] object §[p899]

For web developers (non-normative)

***window*[*name*]**

Returns the indicated element or collection of elements.

As a general rule, relying on this will lead to brittle code. Which IDs end up mapping to this API can vary over time, as new features are added to the web platform, for example. Instead of this, use `document.getElementById()` or `document.querySelector()`.

The **document-tree child navigable target name property set** of a Window[p892] object *window* is the return value of running these steps:

1. Let *children* be the document-tree child navigables[p958] of *window*'s associated Document[p894].
2. Let *firstNamedChildren* be an empty ordered set.
3. For each *navigable* of *children*:
    1. Let *name* be *navigable*'s target name[p953].
    2. If *name* is the empty string, then continue.
    3. If *firstNamedChildren* contains a navigable[p952] whose target name[p953] is *name*, then continue.
    4. Append *navigable* to *firstNamedChildren*.
4. Let *names* be an empty ordered set.
5. For each *navigable* of *firstNamedChildren*:
    1. Let *name* be *navigable*'s target name[p953].
    2. If *navigable*'s active document[p952]'s origin is same origin[p870] with *window*'s relevant settings object[p1039]'s origin[p1032], then append *name* to *names*.
6. Return *names*.

Example

The two seperate iterations mean that in the following example, hosted on `https://example.org/`, assuming `https://elsewhere.example/` sets window.name[p898] to "`spices`", evaluating `window.spices` after everything has loaded will yield undefined:

```
<iframe src=https://elsewhere.example.com/></iframe>
<iframe name=spices></iframe>
```

The Window[p892] object supports named properties. The supported property names of a Window[p892] object *window* at any moment consist of the following, in tree order according to the element that contributed them, ignoring later duplicates:

- *window*'s document-tree child navigable target name property set[p899];
- the value of the name content attribute for all embed[p391], form[p505], img[p338], and object[p394] elements that have a non-empty name content attribute and are in a document tree with *window*'s associated Document[p894] as their root; and
- the value of the id[p151] content attribute for all HTML elements[p45] that have a non-empty id[p151] content attribute and are in a document tree with *window*'s associated Document[p894] as their root.

To determine the value of a named property *name* in a Window[p892] object *window*, the user agent must return the value obtained using the following steps:

1. Let *objects* be the list of named objects[p900] of *window* with the name *name*.

   Note

   There will be at least one such object, since the algorithm would otherwise not have been invoked by Web IDL.

2. If *objects* contains a navigable[p952], then:
   1. Let *container* be the first navigable container[p955] in *window*'s associated Document[p894]'s descendants whose content navigable[p955] is in *objects*.
   2. Return *container*'s content navigable[p955]'s active WindowProxy[p952].
3. Otherwise, if *objects* has only one element, return that element.
4. Otherwise return an HTMLCollection rooted at *window*'s associated Document[p894], whose filter matches only named objects[p900] of *window* with the name *name*. (By definition, these will all be elements.)

Named objects of Window[p892] object *window* with the name *name*, for the purposes of the above algorithm, consist of the following:

- document-tree child navigables[p958] of *window*'s associated Document[p894] whose target name[p953] is *name*;
- embed[p391], form[p505], img[p338], or object[p394] elements that have a name content attribute whose value is *name* and are in a document tree with *window*'s associated Document[p894] as their root; and
- HTML elements[p45] that have an id[p151] content attribute whose value is *name* and are in a document tree with *window*'s associated Document[p894] as their root.

Note

Since the Window[p892] interface has the [Global] extended attribute, its named properties follow the rules for named properties objects rather than legacy platform objects.

7.2.2.4 Accessing related windows §[p900]

For web developers (non-normative)

***window*.top**[p901]

Returns the WindowProxy[p904] for the top-level traversable[p953].

***window*.opener**[p901] **[= *value*]**

Returns the WindowProxy[p904] for the opener browsing context[p961].

Returns null if there isn't one or if it has been set to null.

Can be set to null.

***window*.parent**[p901]

Returns the WindowProxy[p904] for the parent navigable[p952].

***window*.frameElement**[p901]

Returns the navigable container[p955] element.

Returns null if there isn't one, and in cross-origin situations.

The **top** getter steps are:

1. If this's navigable[p894] is null, then return null.
2. Return this's navigable[p894]'s top-level traversable[p954]'s active WindowProxy[p952].

The **opener** getter steps are:

1. Let *current* be this's browsing context[p894].
2. If *current* is null, then return null.
3. If *current*'s opener browsing context[p961] is null, then return null.
4. Return *current*'s opener browsing context[p961]'s WindowProxy[p904] object.

The opener[p901] setter steps are:

1. If the given value is null and this's browsing context[p894] is non-null, then set this's browsing context[p894]'s opener browsing context[p961] to null.
2. If the given value is non-null, then return ? OrdinaryDefineOwnProperty(this, "opener", { [[Value]]: the given value, [[Writable]]: true, [[Enumerable]]: true, [[Configurable]]: true }).

Note

Setting window.opener[p901] to null clears the opener browsing context[p961] reference. In practice, this prevents future scripts from accessing their opener browsing context[p961]'s Window[p892] object.

By default, scripts can access their opener browsing context[p961]'s Window[p892] object through the window.opener[p901] getter. E.g., a script can set window.opener.location, causing the opener browsing context[p961] to navigate.

The **parent** getter steps are:

1. Let *navigable* be this's navigable[p894].
2. If *navigable* is null, then return null.
3. If *navigable*'s parent[p952] is not null, then set *navigable* to *navigable*'s parent[p952].
4. Return *navigable*'s active WindowProxy[p952].

The **frameElement** getter steps are:

1. Let *current* be this's node navigable[p953].
2. If *current* is null, then return null.
3. Let *container* be *current*'s container[p955].
4. If *container* is null, then return null.
5. If *container*'s node document's origin is not same origin-domain[p870] with the current settings object[p1038]'s origin[p1032], then return null.
6. Return *container*.

Example

An example of when these properties can return null is as follows:

```
<!DOCTYPE html>
<iframe></iframe>

<script>
"use strict";
const element = document.querySelector("iframe");
```

```
const iframeWindow = element.contentWindow;
element.remove();

console.assert(iframeWindow.top === null);
console.assert(iframeWindow.parent === null);
console.assert(iframeWindow.frameElement === null);
</script>
```

Here the browsing context[p961] corresponding to `iframeWindow` was nulled out[p1023] when `element` was removed from the document.

7.2.2.5 Historical browser interface element APIs §[p902]

For historical reasons, the `Window`[p892] interface had some properties that represented the visibility of certain web browser interface elements.

For privacy and interoperability reasons, those properties now return values that represent whether the `Window`[p892]'s browsing context[p894]'s is popup[p961] property is true or false.

Each interface element is represented by a `BarProp`[p902] object:

IDL
```
[Exposed=Window]
interface BarProp {
  readonly attribute boolean visible;
};
```

For web developers (non-normative)

***window*.locationbar**[p903]**.visible**[p902]
***window*.menubar**[p903]**.visible**[p902]
***window*.personalbar**[p903]**.visible**[p902]
***window*.scrollbars**[p903]**.visible**[p902]
***window*.statusbar**[p903]**.visible**[p902]
***window*.toolbar**[p903]**.visible**[p902]

Returns true if the `Window`[p892] is not a popup; otherwise, returns false.

The **`visible`** getter steps are:

1. Let *browsingContext* be this's relevant global object[p1039]'s browsing context[p894].
2. If *browsingContext* is null, then return true.
3. Return the negation of *browsingContext*'s top-level browsing context[p964]'s is popup[p961].

The following `BarProp`[p902] objects must exist for each `Window`[p892] object:

The location bar* `BarProp` *object

Historically represented the user interface element that contains a control that displays the browser's location bar.

The menu bar* `BarProp` *object

Historically represented the user interface element that contains a list of commands in menu form, or some similar interface concept.

The personal bar* `BarProp` *object

Historically represented the user interface element that contains links to the user's favorite pages, or some similar interface concept.

The scrollbar* `BarProp` *object

Historically represented the user interface element that contains a scrolling mechanism, or some similar interface concept.

The status bar `BarProp` object

Historically represented a user interface element found immediately below or after the document, as appropriate for the user's media, which typically provides information about ongoing network activity or information about elements that the user's pointing device is currently indicating.

The toolbar `BarProp` object

Historically represented the user interface element found immediately above or before the document, as appropriate for the user's media, which typically provides session history traversal[p1002] controls (back and forward buttons, reload buttons, etc.).

The **`locationbar`** attribute must return the location bar `BarProp` object[p902].

The **`menubar`** attribute must return the menu bar `BarProp` object[p902].

The **`personalbar`** attribute must return the personal bar `BarProp` object[p902].

The **`scrollbars`** attribute must return the scrollbar `BarProp` object[p902].

The **`statusbar`** attribute must return the status bar `BarProp` object[p903].

The **`toolbar`** attribute must return the toolbar `BarProp` object[p903].

For historical reasons, the **`status`** attribute on the `Window`[p892] object must, on getting, return the last string it was set to, and on setting, must set itself to the new value. When the `Window`[p892] object is created, the attribute must be set to the empty string. It does not do anything else.

7.2.2.6 Script settings for `Window`[p892] objects §[p903]

To **set up a window environment settings object**, given a URL *creationURL*, a JavaScript execution context *execution context*, null or an environment[p1031] *reservedEnvironment*, a URL *topLevelCreationURL*, and an origin[p869] *topLevelOrigin*, run these steps:

1. Let *realm* be the value of *execution context*'s Realm component.
2. Let *window* be *realm*'s global object[p1033].
3. Let *settings object* be a new environment settings object[p1032] whose algorithms are defined as follows:

   The realm execution context[p1032]

   Return *execution context*.

   The module map[p1032]

   Return the module map[p128] of *window*'s associated `Document`[p894].

   The API URL character encoding[p1032]

   Return the current character encoding of *window*'s associated `Document`[p894].

   The API base URL[p1032]

   Return the current base URL[p94] of *window*'s associated `Document`[p894].

   The origin[p1032]

   Return the origin of *window*'s associated `Document`[p894].

   The policy container[p1032]

   Return the policy container[p128] of *window*'s associated `Document`[p894].

   The cross-origin isolated capability[p1032]

   Return true if both of the following hold, and false otherwise:

   1. *realm*'s agent cluster's cross-origin-isolation mode[p1029] is "`concrete`[p965]", and
   2. *window*'s associated `Document`[p894] is allowed to use[p390] the "`cross-origin-isolated`[p72]" feature.

The time origin[p1032]

Return *window*'s associated Document[p894]'s load timing info[p131]'s navigation start time[p131].

4. If *reservedEnvironment* is non-null, then:

    1. Set *settings object*'s id[p1031] to *reservedEnvironment*'s id[p1031], target browsing context[p1032] to *reservedEnvironment*'s target browsing context[p1032], and active service worker[p1032] to *reservedEnvironment*'s active service worker[p1032].

    2. Set *reservedEnvironment*'s id[p1031] to the empty string.

    Note

    The identity of the reserved environment is considered to be fully transferred to the created environment settings object[p1032]. The reserved environment is not searchable by the environment[p1031]'s id[p1031] from this point on.

5. Otherwise, set *settings object*'s id[p1031] to a new unique opaque string, *settings object*'s target browsing context[p1032] to null, and *settings object*'s active service worker[p1032] to null.

6. Set *settings object*'s creation URL[p1031] to *creationURL*, *settings object*'s top-level creation URL[p1031] to *topLevelCreationURL*, and *settings object*'s top-level origin[p1031] to *topLevelOrigin*.

7. Set *realm*'s [[HostDefined]] field to *settings object*.

7.2.3 The WindowProxy[p904] exotic object §[p904]

A **WindowProxy** is an exotic object that wraps a Window[p892] ordinary object, indirecting most operations through to the wrapped object. Each browsing context[p961] has an associated WindowProxy[p904] object. When the browsing context[p961] is navigated[p977], the Window[p892] object wrapped by the browsing context[p961]'s associated WindowProxy[p904] object is changed.

The WindowProxy[p904] exotic object must use the ordinary internal methods except where it is explicitly specified otherwise below.

There is no WindowProxy[p904] interface object.

Every WindowProxy[p904] object has a **[[Window]]** internal slot representing the wrapped Window[p892] object.

Note

Although WindowProxy[p904] is named as a "proxy", it does not do polymorphic dispatch on its target's internal methods as a real proxy would, due to a desire to reuse machinery between WindowProxy[p904] and Location[p908] objects. As long as the Window[p892] object remains an ordinary object this is unobservable and can be implemented either way.

7.2.3.1 [[GetPrototypeOf]] ( ) §[p904]

1. Let *W* be the value of the [[Window]][p904] internal slot of **this**.

2. If IsPlatformObjectSameOrigin[p890](*W*) is true, then return ! OrdinaryGetPrototypeOf(*W*).

3. Return null.

7.2.3.2 [[SetPrototypeOf]] (*V*) §[p904]

1. Return ! SetImmutablePrototype(**this**, *V*).

7.2.3.3 [[IsExtensible]] ( ) §[p904]

1. Return true.

7.2.3.4 [[PreventExtensions]] ( ) §p905

1. Return false.

7.2.3.5 [[GetOwnProperty]] (*P*) §p905

1. Let *W* be the value of the [[Window]]p904 internal slot of **this**.
2. If *P* is an array index property name, then:
    1. Let *index* be ! ToUint32(*P*).
    2. Let *children* be the document-tree child navigablesp958 of *W*'s associated `Document`p894.
    3. Let *value* be undefined.
    4. If *index* is less than *children*'s size, then:
        1. Sort *children* in ascending order, with *navigableA* being less than *navigableB* if *navigableA*'s containerp955 was inserted into *W*'s associated `Document`p894 earlier than *navigableB*'s containerp955 was.
        2. Set *value* to *children*[*index*]'s active `WindowProxy`p952.
    5. If *value* is undefined, then:
        1. If IsPlatformObjectSameOriginp890(*W*) is true, then return undefined.
        2. Throw a `"SecurityError"` `DOMException`.
    6. Return PropertyDescriptor{ [[Value]]: *value*, [[Writable]]: false, [[Enumerable]]: true, [[Configurable]]: true }.
3. If IsPlatformObjectSameOriginp890(*W*) is true, then return ! OrdinaryGetOwnProperty(*W*, *P*).

    Note

    This is a willful violationp28 of the JavaScript specification's invariants of the essential internal methods to maintain compatibility with existing web content. See tc39/ecma262 issue #672 for more information. [JAVASCRIPT]p1414

4. Let *property* be CrossOriginGetOwnPropertyHelperp891(*W*, *P*).
5. If *property* is not undefined, then return *property*.
6. If *property* is undefined and *P* is in *W*'s document-tree child navigable target name property setp899, then:
    1. Let *value* be the active `WindowProxy`p952 of the named objectp900 of *W* with the name *P*.
    2. Return PropertyDescriptor{ [[Value]]: *value*, [[Enumerable]]: false, [[Writable]]: false, [[Configurable]]: true }.

        Note

        The reason the property descriptors are non-enumerable, despite this mismatching the same-origin behavior, is for compatibility with existing web content. See issue #3183 for details.

7. Return ? CrossOriginPropertyFallbackp890(*P*).

7.2.3.6 [[DefineOwnProperty]] (*P*, *Desc*) §p905

1. Let *W* be the value of the [[Window]]p904 internal slot of **this**.
2. If IsPlatformObjectSameOriginp890(*W*) is true, then:
    1. If *P* is an array index property name, return false.
    2. Return ? OrdinaryDefineOwnProperty(*W*, *P*, *Desc*).

Note

This is a willful violation[p28] of the JavaScript specification's invariants of the essential internal methods to maintain compatibility with existing web content. See tc39/ecma262 issue #672 for more information. [JAVASCRIPT][p1414]

3. Throw a "SecurityError" DOMException.

7.2.3.7 [[Get]] (*P*, *Receiver*) §[p906]

1. Let *W* be the value of the [[Window]][p904] internal slot of **this**.
2. Check if an access between two browsing contexts should be reported[p878], given the current global object[p1038]'s browsing context[p894], *W*'s browsing context[p894], *P*, and the current settings object[p1038].
3. If IsPlatformObjectSameOrigin[p890](*W*) is true, then return ? OrdinaryGet(**this**, *P*, *Receiver*).
4. Return ? CrossOriginGet[p892](**this**, *P*, *Receiver*).

Note

this *is passed rather than* W *as OrdinaryGet and CrossOriginGet[p892] will invoke the [[GetOwnProperty]][p905] internal method.*

7.2.3.8 [[Set]] (*P*, *V*, *Receiver*) §[p906]

1. Let *W* be the value of the [[Window]][p904] internal slot of **this**.
2. Check if an access between two browsing contexts should be reported[p878], given the current global object[p1038]'s browsing context[p961], *W*'s browsing context[p961], *P*, and the current settings object[p1038].
3. If IsPlatformObjectSameOrigin[p890](*W*) is true, then:
    1. If *P* is an array index property name, then return false.
    2. Return ? OrdinarySet(*W*, *P*, *V*, *Receiver*).
4. Return ? CrossOriginSet[p892](**this**, *P*, *V*, *Receiver*).

Note

this *is passed rather than* W *as CrossOriginSet[p892] will invoke the [[GetOwnProperty]][p905] internal method.*

7.2.3.9 [[Delete]] (*P*) §[p906]

1. Let *W* be the value of the [[Window]][p904] internal slot of **this**.
2. If IsPlatformObjectSameOrigin[p890](*W*) is true, then:
    1. If *P* is an array index property name, then:
        1. Let *desc* be ! **this**.[[GetOwnProperty]](*P*).
        2. If *desc* is undefined, then return true.
        3. Return false.
    2. Return ? OrdinaryDelete(*W*, *P*).
3. Throw a "SecurityError" DOMException.

7.2.3.10 [[OwnPropertyKeys]] ( ) §p907

1. Let *W* be the value of the [[Window]]p904 internal slot of **this**.
2. Let *maxProperties* be *W*'s associated Documentp894's document-tree child navigablesp958's size.
3. Let *keys* be the range 0 to *maxProperties*, exclusive.
4. If IsPlatformObjectSameOriginp890(*W*) is true, then return the concatenation of *keys* and OrdinaryOwnPropertyKeys(*W*).
5. Return the concatenation of *keys* and ! CrossOriginOwnPropertyKeysp892(*W*).

7.2.4 The Locationp908 interface §p907

Each Windowp892 object is associated with a unique instance of a Locationp908 object, allocated when the Windowp892 object is created.

⚠Warning!

The Locationp908 exotic object is defined through a mishmash of IDL, invocation of JavaScript internal methods post-creation, and overridden JavaScript internal methods. Coupled with its scary security policy, please take extra care while implementing this excrescence.

To create a Locationp908 object, run these steps:

1. Let *location* be a new Locationp908 platform object.
2. Let *valueOf* be *location*'s relevant realmp1039.[[Intrinsics]].[[%Object.prototype.valueOf%]].
3. Perform ! *location*.[[DefineOwnProperty]]("`valueOf`", { [[Value]]: *valueOf*, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }).
4. Perform ! *location*.[[DefineOwnProperty]](@@toPrimitivep56, { [[Value]]: undefined, [[Writable]]: false, [[Enumerable]]: false, [[Configurable]]: false }).
5. Set the value of the [[DefaultProperties]]p913 internal slot of *location* to *location*.[[OwnPropertyKeys]]().
6. Return *location*.

Note

The addition of `valueOf` and @@toPrimitivep56 own data properties, as well as the fact that all of Locationp908's IDL attributes are marked [LegacyUnforgeable], is required by legacy code that consulted the Locationp908 interface, or stringified it, to determine the document URL, and then used it in a security-sensitive way. In particular, the `valueOf`, @@toPrimitivep56, and [LegacyUnforgeable] stringifier mitigations ensure that code such as `foo[location] = bar` or `location + ""` cannot be misdirected.

For web developers (non-normative)

***document*.location**p907 **[= *value*]**

***window*.location**p907 **[= *value*]**

Returns a Locationp908 object with the current page's location.

Can be set, to navigate to another page.

The Documentp127 object's **location** getter steps are to return this's relevant global objectp1039's Locationp908 object, if this is fully activep966, and null otherwise.

The Windowp892 object's **location** getter steps are to return this's Locationp908 object.

Locationp908 objects provide a representation of the URL of their associated Documentp127, as well as methods for navigatingp977 and reloadingp990 the associated navigablep952.

IDL
```
[Exposed=Window]
```

```
interface Location { // but see also additional creation steps and overridden internal methods
  [LegacyUnforgeable] stringifier attribute USVString href;
  [LegacyUnforgeable] readonly attribute USVString origin;
  [LegacyUnforgeable] attribute USVString protocol;
  [LegacyUnforgeable] attribute USVString host;
  [LegacyUnforgeable] attribute USVString hostname;
  [LegacyUnforgeable] attribute USVString port;
  [LegacyUnforgeable] attribute USVString pathname;
  [LegacyUnforgeable] attribute USVString search;
  [LegacyUnforgeable] attribute USVString hash;

  [LegacyUnforgeable] undefined assign(USVString url);
  [LegacyUnforgeable] undefined replace(USVString url);
  [LegacyUnforgeable] undefined reload();

  [LegacyUnforgeable, SameObject] readonly attribute DOMStringList ancestorOrigins;
};
```

For web developers (non-normative)

***location*.toString()**

***location*.href**[p909]

Returns the Location[p908] object's URL.

Can be set, to navigate to the given URL.

***location*.origin**[p909]

Returns the Location[p908] object's URL's origin.

***location*.protocol**[p910]

Returns the Location[p908] object's URL's scheme.

Can be set, to navigate to the same URL with a changed scheme.

***location*.host**[p910]

Returns the Location[p908] object's URL's host and port (if different from the default port for the scheme).

Can be set, to navigate to the same URL with a changed host and port.

***location*.hostname**[p910]

Returns the Location[p908] object's URL's host.

Can be set, to navigate to the same URL with a changed host.

***location*.port**[p911]

Returns the Location[p908] object's URL's port.

Can be set, to navigate to the same URL with a changed port.

***location*.pathname**[p911]

Returns the Location[p908] object's URL's path.

Can be set, to navigate to the same URL with a changed path.

***location*.search**[p911]

Returns the Location[p908] object's URL's query (includes leading "?" if non-empty).

Can be set, to navigate to the same URL with a changed query (ignores leading "?").

***location*.hash**[p912]

Returns the Location[p908] object's URL's fragment (includes leading "#" if non-empty).

Can be set, to navigate to the same URL with a changed fragment (ignores leading "#").

***location*.assign**[p912]**(*url*)**

Navigates to the given URL.

***location*.replace**[p913]**(*url*)**

Removes the current page from the session history and navigates to the given URL.

***location*.reload[p913]()**

Reloads the current page.

***location*.ancestorOrigins[p913]**

Returns a DOMStringList[p113] object listing the origins of the ancestor navigables[p957]' active documents[p952].

A Location[p908] object has an associated **relevant Document**, which is its relevant global object[p1039]'s browsing context[p894]'s active document[p961], if this Location[p908] object's relevant global object[p1039]'s browsing context[p894] is non-null, and null otherwise.

A Location[p908] object has an associated **url**, which is this Location[p908] object's relevant Document[p909]'s URL, if this Location[p908] object's relevant Document[p909] is non-null, and about:blank[p53] otherwise.

A Location[p908] object has an associated **ancestor origins list**. When a Location[p908] object is created, its ancestor origins list[p909] must be set to a DOMStringList[p113] object whose associated list is the list of strings that the following steps would produce:

1. Let *output* be a new list of strings.
2. Let *current* be the Location[p908] object's relevant Document[p909].
3. While *current*'s container document[p955] is non-null:
    1. Set *current* to *current*'s container document[p955].
    2. Append the serialization[p869] of *current*'s origin to *output*.
4. Return *output*.

To **Location-object navigate** a Location[p908] object *location* to a URL *url*, optionally given a history handling behavior[p976] *historyHandling* (default "auto[p976]"):

1. Let *navigable* be *location*'s relevant global object[p1039]'s navigable[p894].
2. Let *sourceDocument* be the incumbent global object[p1036]'s associated Document[p894].
3. If *location*'s relevant Document[p909] is not yet completely loaded[p1021], and the incumbent global object[p1036] does not have transient activation[p811], then set *historyHandling* to "replace[p976]".
4. Navigate[p977] *navigable* to *url* using *sourceDocument*, with *exceptionsEnabled*[p977] set to true and *historyHandling*[p977] set to *historyHandling*.

The **href** getter steps are:

1. If this's relevant Document[p909] is non-null and its origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
2. Return this's url[p909], serialized.

The href[p909] setter steps are:

1. If this's relevant Document[p909] is null, then return.
2. Parse[p95] the given value relative to the entry settings object[p1035]. If that failed, throw a "SyntaxError" DOMException.
3. Location-object navigate[p909] this to the resulting URL record[p95].

Note

The href[p909] *setter intentionally has no security check.*

The **origin** getter steps are:

1. If this's relevant Document[p909] is non-null and its origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
2. Return the serialization[p869] of this's url[p909]'s origin.

The **protocol** getter steps are:

1. If this's relevant Document[p909] is non-null and its origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
2. Return this's url[p909]'s scheme, followed by ":".

The protocol[p910] setter steps are:

1. If this's relevant Document[p909] is null, then return.
2. If this's relevant Document[p909]'s origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
3. Let *copyURL* be a copy of this's url[p909].
4. Let *possibleFailure* be the result of basic URL parsing the given value, followed by ":", with *copyURL* as *url* and scheme start state as *state override*.

   Note

   Because the URL parser ignores multiple consecutive colons, providing a value of "https:" *(or even* "https::::") *is the same as providing a value of* "https".

5. If *possibleFailure* is failure, then throw a "SyntaxError" DOMException.
6. If *copyURL*'s scheme is not an HTTP(S) scheme, then terminate these steps.
7. Location-object navigate[p909] this to *copyURL*.

The **host** getter steps are:

1. If this's relevant Document[p909] is non-null and its origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
2. Let *url* be this's url[p909].
3. If *url*'s host is null, return the empty string.
4. If *url*'s port is null, return *url*'s host, serialized.
5. Return *url*'s host, serialized, followed by ":" and *url*'s port, serialized.

The host[p910] setter steps are:

1. If this's relevant Document[p909] is null, then return.
2. If this's relevant Document[p909]'s origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
3. Let *copyURL* be a copy of this's url[p909].
4. If *copyURL* has an opaque path, then return.
5. Basic URL parse the given value, with *copyURL* as *url* and host state as *state override*.
6. Location-object navigate[p909] this to *copyURL*.

The **hostname** getter steps are:

1. If this's relevant Document[p909] is non-null and its origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
2. If this's url[p909]'s host is null, return the empty string.
3. Return this's url[p909]'s host, serialized.

The hostname[p910] setter steps are:

1. If this's relevant Document[p909] is null, then return.

2. If this's relevant Document[p909]'s origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
3. Let *copyURL* be a copy of this's url[p909].
4. If *copyURL* has an opaque path, then return.
5. Basic URL parse the given value, with *copyURL* as *url* and hostname state as *state override*.
6. Location-object navigate[p909] this to *copyURL*.

The **port** getter steps are:

1. If this's relevant Document[p909] is non-null and its origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
2. If this's url[p909]'s port is null, return the empty string.
3. Return this's url[p909]'s port, serialized.

The port[p911] setter steps are:

1. If this's relevant Document[p909] is null, then return.
2. If this's relevant Document[p909]'s origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
3. Let *copyURL* be a copy of this's url[p909].
4. If *copyURL* cannot have a username/password/port, then return.
5. If the given value is the empty string, then set *copyURL*'s port to null.
6. Otherwise, basic URL parse the given value, with *copyURL* as *url* and port state as *state override*.
7. Location-object navigate[p909] this to *copyURL*.

The **pathname** getter steps are:

1. If this's relevant Document[p909] is non-null and its origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
2. Return the result of URL path serializing this Location[p908] object's url[p909].

The pathname[p911] setter steps are:

1. If this's relevant Document[p909] is null, then return.
2. If this's relevant Document[p909]'s origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
3. Let *copyURL* be a copy of this's url[p909].
4. If *copyURL* has an opaque path, then return.
5. Set *copyURL*'s path to the empty list.
6. Basic URL parse the given value, with *copyURL* as *url* and path start state as *state override*.
7. Location-object navigate[p909] this to *copyURL*.

The **search** getter steps are:

1. If this's relevant Document[p909] is non-null and its origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
2. If this's url[p909]'s query is either null or the empty string, return the empty string.
3. Return "?", followed by this's url[p909]'s query.

The `search`[p911] setter steps are:

1. If this's relevant `Document`[p909] is null, then return.
2. If this's relevant `Document`[p909]'s origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a `"SecurityError"` `DOMException`.
3. Let *copyURL* be a copy of this's url[p909].
4. If the given value is the empty string, set *copyURL*'s query to null.
5. Otherwise, run these substeps:
    1. Let *input* be the given value with a single leading "?" removed, if any.
    2. Set *copyURL*'s query to the empty string.
    3. Basic URL parse *input*, with null, the relevant `Document`[p909]'s document's character encoding, *copyURL* as *url*, and query state as *state override*.
6. `Location`-object navigate[p909] this to *copyURL*.

The **`hash`** getter steps are:

1. If this's relevant `Document`[p909] is non-null and its origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a `"SecurityError"` `DOMException`.
2. If this's url[p909]'s fragment is either null or the empty string, return the empty string.
3. Return "#", followed by this's url[p909]'s fragment.

The `hash`[p912] setter steps are:

1. If this's relevant `Document`[p909] is null, then return.
2. If this's relevant `Document`[p909]'s origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a `"SecurityError"` `DOMException`.
3. Let *copyURL* be a copy of this's url[p909].
4. Let *input* be the given value with a single leading "#" removed, if any.
5. Set *copyURL*'s fragment to the empty string.
6. Basic URL parse *input*, with *copyURL* as *url* and fragment state as *state override*.
7. If *copyURL*'s fragment is this's url[p909]'s fragment, then return.

    Note

    This bailout is necessary for compatibility with deployed content, which redundantly sets `location.hash` on scroll. It does not apply to other mechanisms of fragment navigation, such as the `location.href`[p909] setter or `location.assign()`[p912].

8. `Location`-object navigate[p909] this to *copyURL*.

Note

Unlike the equivalent API for the `a`[p252] and `area`[p463] elements, the `hash`[p912] setter does not special case the empty string, to remain compatible with deployed scripts.

The **`assign(`*`url`*`)`** method steps are:

1. If this's relevant `Document`[p909] is null, then return.
2. If this's relevant `Document`[p909]'s origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a `"SecurityError"` `DOMException`.
3. Parse[p95] *url* relative to the entry settings object[p1035]. If that failed, throw a `"SyntaxError"` `DOMException`.

4. Location-object navigate[p909] this to the resulting URL record[p95].

The **replace(*url*)** method steps are:

1. If this's relevant Document[p909] is null, then return.
2. Parse[p95] *url* relative to the entry settings object[p1035]. If that failed, throw a "SyntaxError" DOMException.
3. Location-object navigate[p909] this to the resulting URL record[p95] given "replace[p976]".

Note

The replace()[p913] method intentionally has no security check.

The **reload()** method steps are:

1. Let *document* be this's relevant Document[p909].
2. If *document* is null, then return.
3. If *document*'s origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
4. Reload[p990] *document*'s node navigable[p953].

The **ancestorOrigins** getter steps are:

1. If this's relevant Document[p909] is null, then return an empty list.
2. If this's relevant Document[p909]'s origin is not same origin-domain[p870] with the entry settings object[p1035]'s origin[p1032], then throw a "SecurityError" DOMException.
3. Otherwise, return this's ancestor origins list[p909].

⚠Warning!

The details of how the ancestorOrigins[p913] attribute works are still controversial and might change. See issue #1918 for more information.

As explained earlier, the Location[p908] exotic object requires additional logic beyond IDL for security purposes. The Location[p908] object must use the ordinary internal methods except where it is explicitly specified otherwise below.

Also, every Location[p908] object has a **[[DefaultProperties]]** internal slot representing its own properties at time of its creation.

7.2.4.1 [[GetPrototypeOf]] ( ) §[p913]

1. If IsPlatformObjectSameOrigin[p890](**this**) is true, then return ! OrdinaryGetPrototypeOf(**this**).
2. Return null.

7.2.4.2 [[SetPrototypeOf]] (*V*) §[p913]

1. Return ! SetImmutablePrototype(**this**, *V*).

7.2.4.3 [[IsExtensible]] ( ) §[p913]

1. Return true.

7.2.4.4 [[PreventExtensions]] ( ) §p914

1. Return false.

7.2.4.5 [[GetOwnProperty]] (*P*) §p914

1. If IsPlatformObjectSameOrigin[p890](**this**) is true, then:
    1. Let *desc* be OrdinaryGetOwnProperty(**this**, *P*).
    2. If the value of the [[DefaultProperties]][p913] internal slot of **this** contains *P*, then set *desc*.[[Configurable]] to true.
    3. Return *desc*.
2. Let *property* be CrossOriginGetOwnPropertyHelper[p891](**this**, *P*).
3. If *property* is not undefined, then return *property*.
4. Return ? CrossOriginPropertyFallback[p890](*P*).

7.2.4.6 [[DefineOwnProperty]] (*P*, *Desc*) §p914

1. If IsPlatformObjectSameOrigin[p890](**this**) is true, then:
    1. If the value of the [[DefaultProperties]][p913] internal slot of **this** contains *P*, then return false.
    2. Return ? OrdinaryDefineOwnProperty(**this**, *P*, *Desc*).
2. Throw a `"SecurityError"` `DOMException`.

7.2.4.7 [[Get]] (*P*, *Receiver*) §p914

1. If IsPlatformObjectSameOrigin[p890](**this**) is true, then return ? OrdinaryGet(**this**, *P*, *Receiver*).
2. Return ? CrossOriginGet[p892](**this**, *P*, *Receiver*).

7.2.4.8 [[Set]] (*P*, *V*, *Receiver*) §p914

1. If IsPlatformObjectSameOrigin[p890](**this**) is true, then return ? OrdinarySet(**this**, *P*, *V*, *Receiver*).
2. Return ? CrossOriginSet[p892](**this**, *P*, *V*, *Receiver*).

7.2.4.9 [[Delete]] (*P*) §p914

1. If IsPlatformObjectSameOrigin[p890](**this**) is true, then return ? OrdinaryDelete(**this**, *P*).
2. Throw a `"SecurityError"` `DOMException`.

7.2.4.10 [[OwnPropertyKeys]] ( ) §p914

1. If IsPlatformObjectSameOrigin[p890](**this**) is true, then return OrdinaryOwnPropertyKeys(**this**).
2. Return CrossOriginOwnPropertyKeys[p892](**this**).

7.2.5 The History[p915] interface §[p915]

IDL
```
enum ScrollRestoration { "auto", "manual" };

[Exposed=Window]
interface History {
  readonly attribute unsigned long length;
  attribute ScrollRestoration scrollRestoration;
  readonly attribute any state;
  undefined go(optional long delta = 0);
  undefined back();
  undefined forward();
  undefined pushState(any data, DOMString unused, optional USVString? url = null);
  undefined replaceState(any data, DOMString unused, optional USVString? url = null);
};
```

For web developers (non-normative)

history[p916].length[p916]

Returns the number of overall session history entries[p953] for the current traversable navigable[p953].

history[p916].scrollRestoration[p916]

Returns the scroll restoration mode[p968] of the active session history entry[p952].

history[p916].scrollRestoration[p916] = *value*

Set the scroll restoration mode[p968] of the active session history entry[p952] to *value*.

history[p916].state[p916]

Returns the classic history API state[p968] of the active session history entry[p952], deserialized into a JavaScript value.

history[p916].go[p916]()

Reloads the current page.

history[p916].go[p916](*delta*)

Goes back or forward the specified number of steps in the overall session history entries[p953] list for the current traversable navigable[p953].

A zero delta will reload the current page.

If the delta is out of range, does nothing.

history[p916].back[p916]()

Goes back one step in the overall session history entries[p953] list for the current traversable navigable[p953].

If there is no previous page, does nothing.

history[p916].forward[p916]()

Goes forward one step in the overall session history entries[p953] list for the current traversable navigable[p953].

If there is no next page, does nothing.

history[p916].pushState[p917](*data*, "")

Adds a new entry into session history with its classic history API state[p968] set to a serialization of *data*. The active history entry[p952]'s URL[p968] will be copied over and used for the new entry's URL.

(The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

history[p916].pushState[p917](*data*, "", *url*)

Adds a new entry into session history with its classic history API state[p968] set to a serialization of *data*, and with its URL[p968] set to *url*.

If the current Document[p127] cannot have its URL rewritten[p917] to *url*, a "SecurityError" DOMException will be thrown.

(The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

history[p916].replaceState[p917](*data*, "")

Updates the classic history API state[p968] of the active session history entry[p952] to a structured clone of *data*.

(The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

history[p916]**.replaceState**[p917]**(*data*, "", *url*)**

Updates the classic history API state[p968] of the active session history entry[p952] to a structured clone of *data*, and its URL[p968] to *url*.

If the current Document[p127] cannot have its URL rewritten[p917] to *url*, a "SecurityError" DOMException will be thrown.

(The second parameter exists for historical reasons, and cannot be omitted; passing the empty string is traditional.)

A Document[p127] has a **history object**, a History[p915] object.

The **history** getter steps are to return this's associated Document[p894]'s history object[p916].

Each History[p915] object has **state**, initially null.

Each History[p915] object has a **length**, a non-negative integer, initially 0.

Each History[p915] object has an **index**, a non-negative integer, initially 0.

Note

Although the index[p916] is not directly exposed, it can be inferred from changes to the length[p916] during synchronous navigations. In fact, that is what it's used for.

The **length** getter steps are:

1. If this's relevant global object[p1039]'s associated Document[p894] is not fully active[p966], then throw a "SecurityError" DOMException.
2. Return this's length[p916].

The **scrollRestoration** getter steps are:

1. If this's relevant global object[p1039]'s associated Document[p894] is not fully active[p966], then throw a "SecurityError" DOMException.
2. Return this's node navigable[p953]'s active session history entry[p952]'s scroll restoration mode[p968].

The scrollRestoration[p916] setter steps are:

1. If this's relevant global object[p1039]'s associated Document[p894] is not fully active[p966], then throw a "SecurityError" DOMException.
2. Set this's node navigable[p953]'s active session history entry[p952]'s scroll restoration mode[p968] to the given value.

The **state** getter steps are:

1. If this's relevant global object[p1039]'s associated Document[p894] is not fully active[p966], then throw a "SecurityError" DOMException.
2. Return this's state[p916].

The **go(*delta*)** method steps are to delta traverse[p916] this given *delta*.

The **back()** method steps are to delta traverse[p916] this given −1.

The **forward()** method steps are to delta traverse[p916] this given +1.

To **delta traverse** a History[p915] object *history* given an integer *delta*:

1. Let *document* be *history*'s relevant global object[p1039]'s associated Document[p894].
2. If *document* is not fully active[p966], then throw a "SecurityError" DOMException.
3. If *delta* is 0, then reload[p990] *document*'s node navigable[p953].

4. Traverse the history by a delta[p990] given *document*'s node navigable[p953]'s traversable navigable[p953], *delta*, and with *sourceDocument*[p990] set to *document*.

The **`pushState(data, unused, url)`** method steps are to run the shared history push/replace state steps[p917] given this, *data*, *url*, and "`push`[p976]".

The **`replaceState(data, unused, url)`** method steps are to run the shared history push/replace state steps[p917] given this, *data*, *url*, and "`replace`[p976]".

The **shared history push/replace state steps**, given a `History`[p915] *history*, a value *data*, a scalar value string-or-null *url*, and a history handling behavior[p976] *historyHandling*, are:

1. Let *document* be *history*'s associated `Document`[p127].
2. If *document* is not fully active[p966], then throw a `"SecurityError"` `DOMException`.
3. Optionally, return. (For example, the user agent might disallow calls to these methods that are invoked on a timer, or from event listeners that are not triggered in response to a clear user action, or that are invoked in rapid succession.)
4. Let *serializedData* be StructuredSerializeForStorage[p120](*data*). Rethrow any exceptions.
5. Let *newURL* be *document*'s URL.
6. If *url* is not null or the empty string, then:
    1. Parse[p95] *url*, relative to the relevant settings object[p1039] of *history*.
    2. If that fails, then throw a `"SecurityError"` `DOMException`.
    3. Set *newURL* to the resulting URL record[p95].
    4. If *document* cannot have its URL rewritten[p917] to *newURL*, then throw a `"SecurityError"` `DOMException`.

    Note

    The special case for the empty string here is historical, and leads to different resulting URLs when comparing code such as `location.href = ""` *(which performs URL parsing on the empty string) versus* `history.pushState(null, "", "")` *(which bypasses it).*
7. Let *navigation* be *history*'s relevant global object[p1039]'s navigation API[p922].
8. Let *continue* be the result of firing a push/replace/reload `navigate` event[p944] at *navigation* with *navigationType*[p944] set to *historyHandling*, *isSameDocument*[p944] set to true, *destinationURL*[p944] set to *newURL*, and *classicHistoryAPIState*[p944] set to *serializedData*.
9. If *continue* is false, then return.
10. Run the URL and history update steps[p991] given *document* and *newURL*, with *serializedData*[p991] set to *serializedData* and *historyHandling*[p991] set to *historyHandling*.

User agents may limit the number of state objects added to the session history per page. If a page hits the implementation-defined limit, user agents must remove the entry immediately after the first entry for that `Document`[p127] object in the session history after having added the new entry. (Thus the state history acts as a FIFO buffer for eviction, but as a LIFO buffer for navigation.)

A `Document`[p127] *document* **can have its URL rewritten** to a URL *targetURL* if the following algorithm returns true:

1. Let *documentURL* be *document*'s URL.
2. If *targetURL* and *documentURL* differ in their scheme, username, password, host, or port components, then return false.
3. If *targetURL*'s scheme is an HTTP(S) scheme, then return true. (Differences in path, query, and fragment are allowed for `http:` and `https:` URLs.)
4. If *targetURL*'s scheme is "`file`", and *targetURL* and *documentURL* differ in their path component, then return false. (Differences in query and fragment are allowed for `file:` URLs.)
5. If *targetURL* and *documentURL* differ in their path component or query components, then return false. (Only differences in fragment are allowed for other types of URLs.)
6. Return true.

Example

document's URL	*targetURL*	can have its URL rewritten[p917]
https://example.com/home	https://example.com/home#about	✔
https://example.com/home	https://example.com/home?page=shop	✔
https://example.com/home	https://example.com/shop	✔
https://example.com/home	https://user:pass@example.com/home	✘
https://example.com/home	http://example.com/home	✘
file:///path/to/x	file:///path/to/x#hash	✔
file:///path/to/x	file:///path/to/x?search	✔
file:///path/to/x	file:///path/to/y	✘
about:blank	about:blank#hash	✔
about:blank	about:blank?search	✘
about:blank	about:srcdoc	✘

Note how only the URL of the Document[p127] matters, and not its origin. They can mismatch in cases like about:blank[p53] Document[p127]s with inherited origins, in sandboxed iframe[p383]s, or when the document.domain[p872] setter has been used.

Example

Consider a game where the user can navigate along a line, such that the user is always at some coordinate, and such that the user can bookmark the page corresponding to a particular coordinate, to return to it later.

A static page implementing the x=5 position in such a game could look like the following:

```
<!DOCTYPE HTML>
<!-- this is https://example.com/line?x=5 -->
<html lang="en">
<title>Line Game - 5</title>
<p>You are at coordinate 5 on the line.</p>
<p>
 <a href="?x=6">Advance to 6</a> or
 <a href="?x=4">retreat to 4</a>?
</p>
```

The problem with such a system is that each time the user clicks, the whole page has to be reloaded. Here instead is another way of doing it, using script:

```
<!DOCTYPE HTML>
<!-- this starts off as https://example.com/line?x=5 -->
<html lang="en">
<title>Line Game - 5</title>
<p>You are at coordinate <span id="coord">5</span> on the line.</p>
<p>
 <a href="?x=6" onclick="go(1); return false;">Advance to 6</a> or
 <a href="?x=4" onclick="go(-1); return false;">retreat to 4</a>?
</p>
<script>
```

```
  var currentPage = 5; // prefilled by server
  function go(d) {
    setupPage(currentPage + d);
    history.pushState(currentPage, "", '?x=' + currentPage);
  }
  onpopstate = function(event) {
    setupPage(event.state);
  }
  function setupPage(page) {
    currentPage = page;
    document.title = 'Line Game - ' + currentPage;
    document.getElementById('coord').textContent = currentPage;
    document.links[0].href = '?x=' + (currentPage+1);
    document.links[0].textContent = 'Advance to ' + (currentPage+1);
    document.links[1].href = '?x=' + (currentPage-1);
    document.links[1].textContent = 'retreat to ' + (currentPage-1);
  }
</script>
```

In systems without script, this still works like the previous example. However, users that *do* have script support can now navigate much faster, since there is no network access for the same experience. Furthermore, contrary to the experience the user would have with just a naïve script-based approach, bookmarking and navigating the session history still work.

In the example above, the *data* argument to the `pushState()` [p917] method is the same information as would be sent to the server, but in a more convenient form, so that the script doesn't have to parse the URL each time the user navigates.

Example

Most applications want to use the same scroll restoration mode [p969] value for all of their history entries. To achieve this they can set the `scrollRestoration` [p916] attribute as soon as possible (e.g., in the first `script` [p638] element in the document's `head` [p168] element) to ensure that any entry added to the history session gets the desired scroll restoration mode.

```
<head>
  <script>
       if ('scrollRestoration' in history)
            history.scrollRestoration = 'manual';
  </script>
</head>
```

7.2.6 The navigation API §[p919]

7.2.6.1 Introduction §[p919]

This section is non-normative.

The navigation API, provided by the global `navigation` [p922] property, provides a modern and web application-focused way of managing navigations and history entries. It is a successor to the classic `location` [p907] and `history` [p916] APIs.

One ability the API provides is inspecting session history entries [p968]. For example, the following will display the entries' URLs in an ordered list:

```
const ol = document.createElement("ol");
ol.start = 0; // so that the list items' ordinal values match up with the entry indices

for (const entry of navigation.entries()) {
  const li = document.createElement("li");
```

```
  if (entry.index < navigation.currentEntry.index) {
    li.className = "backward";
  } else if (entry.index > navigation.currentEntry.index) {
    li.className = "forward";
  } else {
    li.className = "current";
  }

  li.textContent = entry.url;
  ol.append(li);
}
```

The navigation.entries()[p928] array contains NavigationHistoryEntry[p926] instances, which have other useful properties in addition to the url[p927] and index[p927] properties shown here. Note that the array only contains NavigationHistoryEntry[p926] objects that represent the current navigable[p952], and thus its contents are not impacted by navigations inside navigable containers[p955] such as iframe[p383]s, or by navigations of the parent navigable[p952] in cases where the navigation API is itself being used inside an iframe[p383]. Additionally, it only contains NavigationHistoryEntry[p926] objects representing same-origin[p869] session history entries[p968], meaning that if the user has visited other origins before or after the current one, there will not be corresponding NavigationHistoryEntry[p926]s.

The navigation API can also be used to navigate, reload, or traverse through the history:

```
<button onclick="navigation.reload()">Reload</button>

<input type="url" id="navigationURL">
<button onclick="navigation.navigate(navigationURL.value)">Navigate</button>

<button id="backButton" onclick="navigation.back()">Back</button>
<button id="forwardButton" onclick="navigation.forward()">Forward</button>

<select id="traversalDestinations"></select>
<button id="goButton" onclick="navigation.traverseTo(traversalDestinations.value)">Traverse To</button>

<script>
backButton.disabled = !navigation.canGoBack;
forwardButton.disabled = !navigation.canGoForward;

for (const entry of navigation.entries()) {
  traversalDestinations.append(new Option(entry.url, entry.key));
}
</script>
```

Note that traversals are again limited to same-origin[p869] destinations, meaning that, for example, navigation.canGoBack[p929] will be false if the previous session history entry[p968] is for a page from another origin.

The most powerful part of the navigation API is the navigate[p1407] event, which fires whenever almost any navigation or traversal occurs in the current navigable[p952]:

```
navigation.onnavigate = event => {
  console.log(event.navigationType); // "push", "replace", "reload", or "traverse"
  console.log(event.destination.url);
  console.log(event.userInitiated);
  // ... and other useful properties
};
```

(The event will not fire for location bar-initiated navigations[p1026], or navigations initiated from other windows, when the destination of the navigation is a new document.)

Much of the time, the event's cancelable property will be true, meaning this event can be canceled using preventDefault():

```
navigation.onnavigate = event => {
  if (event.cancelable && isDisallowedURL(event.destination.url)) {
    alert(`Please don't go to ${event.destination.url}!`);
    event.preventDefault();
  }
};
```

The cancelable property will be false for some "traverse[p924]" navigations, such as those taking place inside child navigables[p955], those crossing to new origins, or when the user attempts to traverse again shortly after a previous call to preventDefault() prevented them from doing so.

The NavigateEvent[p939]'s intercept()[p941] method allows intercepting a navigation and converting it into a same-document navigation:

```
navigation.addEventListener("navigate", e => {
  // Some navigations, e.g. cross-origin navigations, we cannot intercept.
  // Let the browser handle those normally.
  if (!e.canIntercept) {
    return;
  }

  // Similarly, don't intercept fragment navigations or downloads.
  if (e.hashChange || e.downloadRequest !== null) {
    return;
  }

  const url = new URL(event.destination.url);

  if (url.pathname.startsWith("/articles/")) {
    e.intercept({
      async handler() {
        // The URL has already changed, so show a placeholder while
        // fetching the new content, such as a spinner or loading page.
        renderArticlePagePlaceholder();

        // Fetch the new content and display when ready.
        const articleContent = await getArticleContent(url.pathname, { signal: e.signal });
        renderArticlePage(articleContent);
      }
    });
  }
});
```

Note that the handler[p939] function can return a promise to represent the asynchronous progress, and success or failure, of the navigation. While the promise is still pending, browser UI can treat the navigation as ongoing (e.g., by presenting a loading spinner). Other parts of the navigation API are also sensitive to these promises, such as the return value of navigation.navigate()[p930]:

```
const { committed, finished } = await navigation.navigate("/articles/the-navigation-api-is-cool");

// The committed promise will fulfill once the URL has changed, which happens
// immediately (as long as the NavigateEvent wasn't canceled).
await committed;

// The finished promise will fulfill once the Promise returned by handler() has
// fulfilled, which happens once the article is downloaded and rendered. (Or,
// it will reject, if handler() fails along the way).
await finished;
```

7.2.6.2 The Navigation[p922] inteface §[p922]

IDL

```
[Exposed=Window]
interface Navigation : EventTarget {
  sequence<NavigationHistoryEntry> entries();
  readonly attribute NavigationHistoryEntry? currentEntry;
  undefined updateCurrentEntry(NavigationUpdateCurrentEntryOptions options);
  readonly attribute NavigationTransition? transition;

  readonly attribute boolean canGoBack;
  readonly attribute boolean canGoForward;

  NavigationResult navigate(USVString url, optional NavigationNavigateOptions options = {});
  NavigationResult reload(optional NavigationReloadOptions options = {});

  NavigationResult traverseTo(DOMString key, optional NavigationOptions options = {});
  NavigationResult back(optional NavigationOptions options = {});
  NavigationResult forward(optional NavigationOptions options = {});

  attribute EventHandler onnavigate;
  attribute EventHandler onnavigatesuccess;
  attribute EventHandler onnavigateerror;
  attribute EventHandler oncurrententrychange;
};

dictionary NavigationUpdateCurrentEntryOptions {
  required any state;
};

dictionary NavigationOptions {
  any info;
};

dictionary NavigationNavigateOptions : NavigationOptions {
  any state;
  NavigationHistoryBehavior history = "auto";
};

dictionary NavigationReloadOptions : NavigationOptions {
  any state;
};

dictionary NavigationResult {
  Promise<NavigationHistoryEntry> committed;
  Promise<NavigationHistoryEntry> finished;
};

enum NavigationHistoryBehavior {
  "auto",
  "push",
  "replace"
};
```

Each Window[p892] has an associated **navigation API**, which is a Navigation[p922] object. Upon creation of the Window[p892] object, its navigation API[p922] must be set to a new Navigation[p922] object created in the Window[p892] object's relevant realm[p1039].

The **navigation** getter steps are to return this's navigation API[p922].

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported, as event handler IDL attributes[p1084], by all objects implementing the Navigation[p922] interface:

Event handler[p1083]	Event handler event type[p1085]
onnavigate	navigate[p1407]
onnavigatesuccess	navigatesuccess[p1407]
onnavigateerror	navigateerror[p1407]
oncurrententrychange	currententrychange[p1406]

7.2.6.3 Core infrastructure §[p923]

Each Navigation[p922] has an associated **entry list**, a list of NavigationHistoryEntry[p926] objects, initially empty.

Each Navigation[p922] has an associated **current entry index**, an integer, initially −1.

The **current entry** of a Navigation[p922] *navigation* is the result of running the following steps:

1. If *navigation* has entries and events disabled[p923], then return null.
2. Assert: *navigation*'s current entry index[p923] is not −1.
3. Return *navigation*'s entry list[p923][*navigation*'s current entry index[p923]].

A Navigation[p922] *navigation* **has entries and events disabled** if the following steps return true:

1. Let *document* be *navigation*'s relevant global object[p1039]'s associated Document[p894].
2. If *document* is not fully active[p966], then return true.
3. If *document*'s is initial about:blank[p128] is true, then return true.
4. If *document*'s origin is opaque[p869], then return true.
5. Return false.

To **get the navigation API entry index** of a session history entry[p968] *she* within a Navigation[p922] *navigation*:

1. Let *index* be 0.
2. For each *nhe* of *navigation*'s entry list[p923]:
    1. If *nhe*'s session history entry[p927] is equal to *she*, then return *index*.
    2. Increment *index* by 1.
3. Return −1.

A key type used throughout the navigation API is the NavigationType[p923] enumeration:

```
IDL
enum NavigationType {
  "push",
  "replace",
  "reload",
  "traverse"
};
```

This captures the main web developer-visible types of "navigations", which (as noted elsewhere[p974]) do not exactly correspond to this standard's singular navigate[p977] algorithm. The meaning of each value is the following:

"push"

Corresponds to calls to navigate[p977] where the history handling behavior[p976] ends up as "push[p976]", or to history.pushState()[p917].

"replace"

Corresponds to calls to navigate[p977] where the history handling behavior[p976] ends up as "replace[p976]", or to history.replaceState()[p917].

"**reload**"

Corresponds to calls to reload[p990].

"**traverse**"

Corresponds to calls to traverse the history by a delta[p990].

Note

The value space of the NavigationType[p923] *enumeration is a superset of the value space of the specification-internal history handling behavior[p976] type. Several parts of this standard make use of this overlap, by passing in a history handling behavior[p976] to an algorithm that expects a* NavigationType[p923].

7.2.6.4 Initializing and updating the entry list §[p924]

To **initialize the navigation API entries for a new document** given a Navigation[p922] *navigation*, a list of session history entries[p968] *newSHEs*, and a session history entry[p968] *initialSHE*:

1. Assert: *navigation*'s entry list[p923] is empty.
2. Assert: *navigation*'s current entry index[p923] is −1.
3. If *navigation* has entries and events disabled[p923], then return.
4. For each *newSHE* of *newSHEs*:
    1. Let *newNHE* be a new NavigationHistoryEntry[p926] created in the relevant realm[p1039] of *navigation*.
    2. Set *newNHE*'s session history entry[p927] to *newSHE*.
    3. Append *newNHE* to *navigation*'s entry list[p923].

    Note

    newSHEs *will have originally come from getting session history entries for the navigation API[p973], and thus each* newSHE *will be contiguous same[p870] origin[p969] with* initialSHE.

5. Set *navigation*'s current entry index[p923] to the result of getting the navigation API entry index[p923] of *initialSHE* within *navigation*.

To **update the navigation API entries for reactivation** given a Navigation[p922] *navigation*, a list of session history entries[p968] *newSHEs*, and a session history entry[p968] *reactivatedSHE*:

1. If *navigation* has entries and events disabled[p923], then return.
2. Let *newNHEs* be a new empty list.
3. Let *oldNHEs* be a clone of *navigation*'s entry list[p923].
4. For each *newSHE* of *newSHEs*:
    1. Let *newNHE* be null.
    2. If *oldNHEs* contains a NavigationHistoryEntry[p926] *matchingOldNHE* whose session history entry[p927] is *newSHE*, then:
        1. Set *newNHE* to *matchingOldNHE*.
        2. Remove *matchingOldNHE* from *oldNHEs*.
    3. Otherwise:
        1. Set *newNHE* to a new NavigationHistoryEntry[p926] created in the relevant realm[p1039] of *navigation*.
        2. Set *newNHE*'s session history entry[p927] to *newSHE*.
    4. Append *newNHE* to *newNHEs*.

Note

newSHEs will have originally come from getting session history entries for the navigation API[p973], and thus each newSHE *will be contiguous same[p870] origin[p969] with* reactivatedSHE.

Note

By the end of this loop, all `NavigationHistoryEntry`[p926]*s that remain in* oldNHEs *represent session history entries[p968] which have been disposed while the* `Document`[p127] *was in bfcache[p969].*

5. Set *navigation*'s entry list[p622] to *newNHEs*.

6. Set *navigation*'s current entry index[p923] to the result of getting the navigation API entry index[p923] of *reactivatedSHE* within *navigation*.

7. Queue a global task[p1073] on the navigation and traversal task source[p1081] given *navigation*'s relevant global object[p1039] to run the following steps:

    1. For each *disposedNHE* of *oldNHEs*:

        1. Fire an event named `dispose`[p1406] at *disposedNHE*.

Note

We delay these steps by a task to ensure that `dispose`[p1406] *events will fire after the* `pageshow`[p1407] *event. This ensures that* `pageshow`[p1407] *is the first event a page receives upon reactivation[p1010].*

(However, the rest of this algorithm runs before the `pageshow`[p1407] *event fires. This ensures that* `navigation.entries()`[p928] *and* `navigation.currentEntry`[p928] *will have correctly-updated values during any* `pageshow`[p1407] *event handlers.)*

To **update the navigation API entries for a same-document navigation** given a `Navigation`[p922] *navigation*, a session history entry[p968] *destinationSHE*, and a `NavigationType`[p923] *navigationType*:

1. If *navigation* has entries and events disabled[p923], then return.

2. Let *oldCurrentNHE* be the current entry[p923] of *navigation*.

3. Let *disposedNHEs* be a new empty list.

4. If *navigationType* is "`traverse`[p924]", then:

    1. Set *navigation*'s current entry index[p923] to the result of getting the navigation API entry index[p923] of *destinationSHE* within *navigation*.

    2. Assert: *navigation*'s current entry index[p923] is not −1.

Note

This algorithm is only called for same-document traversals. Cross-document traversals will instead call either initialize the navigation API entries for a new document[p924] or update the navigation API entries for reactivation[p924].

5. Otherwise, if *navigationType* is "`push`[p923]", then:

    1. Set *navigation*'s current entry index[p923] to *navigation*'s current entry index[p923] + 1.

    2. Let *i* be *navigation*'s current entry index[p923].

    3. While *i* < *navigation*'s entry list[p923]'s size:

        1. Append *navigation*'s entry list[p923][*i*] to *disposedNHEs*.

        2. Set *i* to *i* + 1.

    4. Remove all items in *disposedNHEs* from *navigation*'s entry list[p923].

6. Otherwise, if *navigationType* is "`replace`[p923]", then:

    1. Append *oldCurrentNHE* to *disposedNHEs*.

7. If *navigationType* is "`push`[p923]" or "`replace`[p923]", then:

1. Let *newNHE* be a new NavigationHistoryEntry[p926] created in the relevant realm[p1039] of *navigation*.
2. Set *newNHE*'s session history entry[p927] to *destinationSHE*.
3. Set *navigation*'s entry list[p923][*navigation*'s current entry index[p923]] to *newNHE*.

8. If *navigation*'s ongoing API method tracker[p934] is non-null, then notify about the committed-to entry[p936] given *navigation*'s ongoing API method tracker[p934] and the current entry[p923] of *navigation*.

   Note

   It is important to do this before firing the dispose[p1406] *or* currententrychange[p1406] *events, since event handlers could start another navigation, or otherwise change the value of* navigation's *ongoing API method tracker*[p934].

9. Prepare to run script[p1052] given *navigation*'s relevant settings object[p1039].

   Note

   See the discussion for other navigation API events[p946] *to understand why we do this.*

10. Fire an event named currententrychange[p1406] at *navigation* using NavigationCurrentEntryChangeEvent[p949], with its navigationType[p949] attribute initialized to *navigationType* and its from[p949] initialized to *oldCurrentNHE*.
11. For each *disposedNHE* of *disposedNHEs*:
    1. Fire an event named dispose[p1406] at *disposedNHE*.
12. Clean up after running script[p1052] given *navigation*'s relevant settings object[p1039].

In implementations, same-document navigations can cause session history entries[p968] to be disposed by falling off the back of the session history entry list. This is not yet handled by the above algorithm (or by any other part of this standard). See issue #8620 to track progress on defining the correct behavior in such cases.

7.2.6.5 The NavigationHistoryEntry[p926] interface §[p926]

IDL

```
[Exposed=Window]
interface NavigationHistoryEntry : EventTarget {
  readonly attribute USVString? url;
  readonly attribute DOMString key;
  readonly attribute DOMString id;
  readonly attribute long long index;
  readonly attribute boolean sameDocument;

  any getState();

  attribute EventHandler ondispose;
};
```

For web developers (non-normative)

***entry*.*url*[p927]**

The URL of this navigation history entry.

This can return null if the entry corresponds to a different Document[p127] than the current one (i.e., if sameDocument[p927] is false), and that Document[p127] was fetched with a referrer policy of "no-referrer" or "origin", since that indicates the Document[p127] in question is hiding its URL even from other same-origin pages.

***entry*.*key*[p927]**

A user agent-generated random UUID string representing this navigation history entry's place in the navigation history list. This value will be reused by other NavigationHistoryEntry[p926] instances that replace this one due to "replace[p923]" navigations, and will survive reloads and session restores.

This is useful for navigating back to this entry in the navigation history list, using navigation.traverseTo(key)[p932].

***entry*.id**[p927]

A user agent-generated random UUID string representing this specific navigation history entry. This value will *not* be reused by other `NavigationHistoryEntry`[p926] instances. This value will survive reloads and session restores.

This is useful for associating data with this navigation history entry using other storage APIs.

***entry*.index**[p927]

The index of this `NavigationHistoryEntry`[p926] within `navigation.entries()`[p928], or −1 if the entry is not in the navigation history entry list.

***entry*.sameDocument**[p927]

Indicates whether or not this navigation history entry is for the same `Document`[p127] as the current one, or not. This will be true, for example, when the entry represents a fragment navigation or single-page app navigation.

***entry*.getState**[p928]**()**

Returns the deserialization[p120] of the state stored in this entry, which was added to the entry using `navigation.navigate()`[p930] or `navigation.updateCurrentEntry()`[p928]. This state survives reloads and session restores.

Note that in general, unless the state value is a primitive, `entry.getState() !== entry.getState()`, since a fresh deserialization is returned each time.

This state is unrelated to the classic history API's `history.state`[p916].

Each `NavigationHistoryEntry`[p926] has an associated **session history entry**, which is a session history entry[p968].

The **key** of a `NavigationHistoryEntry`[p926] *nhe* is given by the return value of the following algorithm:

1. If *nhe*'s relevant global object[p1039]'s associated `Document`[p894] is not fully active[p966], then return the empty string.
2. Return *nhe*'s session history entry[p927]'s navigation API key[p968].

The **ID** of a `NavigationHistoryEntry`[p926] *nhe* is given by the return value of the following algorithm:

1. If *nhe*'s relevant global object[p1039]'s associated `Document`[p894] is not fully active[p966], then return the empty string.
2. Return *nhe*'s session history entry[p927]'s navigation API ID[p968].

The **index** of a `NavigationHistoryEntry`[p926] *nhe* is given by the return value of the following algorithm:

1. If *nhe*'s relevant global object[p1039]'s associated `Document`[p894] is not fully active[p966], then return −1.
2. Return the result of getting the navigation API entry index[p923] of this's session history entry[p927] within this's relevant global object[p1039]'s navigation API[p922].

The **`url`** getter steps are:

1. Let *document* be this's relevant global object[p1039]'s associated `Document`[p894].
2. If *document* is not fully active[p966], then return the empty string.
3. Let *she* be this's session history entry[p927].
4. If *she*'s document[p968] does not equal *document*, and *she*'s document state[p968]'s request referrer policy[p969] is "`no-referrer`" or "`origin`", then return null.
5. Return *she*'s URL[p968], serialized.

The **`key`** getter steps are to return this's key[p927].

The **`id`** getter steps are to return this's ID[p927].

The **`index`** getter steps are to return this's index[p927].

The **`sameDocument`** getter steps are:

1. Let *document* be this's relevant global object[p1039]'s associated `Document`[p894].

2. If *document* is not fully active[p966], then return false.

3. Return true if this's session history entry[p927]'s document[p968] equals *document*, and false otherwise.

The **getState()** method steps are:

1. If this's relevant global object[p1039]'s associated Document[p894] is not fully active[p966], then return undefined.

2. Return StructuredDeserialize[p120](this's session history entry[p927]'s navigation API state[p968]). Rethrow any exceptions.

> **Note**
> *This can in theory throw an exception, if attempting to deserialize a large ArrayBuffer when not enough memory is available.*

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported, as event handler IDL attributes[p1084], by all objects implementing the NavigationHistoryEntry[p926] interface:

Event handler[p1083]	Event handler event type[p1085]
ondispose	dispose[p1406]

7.2.6.6 The history entry list §[p928]

> **For web developers (non-normative)**
>
> ***entries* = navigation[p922].entries()[p928]**
>
> Returns an array of NavigationHistoryEntry[p926] instances represent the current navigation history entry list, i.e., all session history entries[p968] for this navigable[p952] that are same origin[p870] and contiguous to the current session history entry[p952].
>
> **navigation[p922].currentEntry[p928]**
>
> Returns the NavigationHistoryEntry[p926] corresponding to the current session history entry[p952].
>
> **navigation[p922].updateCurrentEntry[p928]({ state[p922] })**
>
> Updates the navigation API state[p968] of the current session history entry[p952], without performing a navigation like navigation.reload()[p931] would do.
>
> This method is best used to capture updates to the page that have already happened, and need to be reflected into the navigation API state. For cases where the state update is meant to drive a page update, instead use navigation.navigate()[p930] or navigation.reload()[p931], which will trigger a navigate[p1407] event.
>
> **navigation[p922].canGoBack[p929]**
>
> Returns true if the current current session history entry[p952] (i.e., currentEntry[p928]) is not the first one in the navigation history entry list (i.e., in entries()[p928]). This means that there is a previous session history entry[p968] for this navigable[p952], and its document state[p968]'s origin[p969] is same origin[p870] with the current Document[p127]'s origin.
>
> **navigation[p922].canGoForward[p929]**
>
> Returns true if the current current session history entry[p952] (i.e., currentEntry[p928]) is not the last one in the navigation history entry list (i.e., in entries()[p928]). This means that there is a next session history entry[p968] for this navigable[p952], and its document state[p968]'s origin[p969] is same origin[p870] with the current Document[p127]'s origin.

The **entries()** method steps are:

1. If this has entries and events disabled[p923], then return the empty list.

2. Return this's entry list[p923].

> **Note**
> *Recall that because of Web IDL's sequence type conversion rules, this will create a new JavaScript array object on each call. That is,* navigation.entries()[p928] !== navigation.entries()[p928].

The **currentEntry** getter steps are to return the current entry[p923] of this.

The **updateCurrentEntry(*options*)** method steps are:

1. Let *current* be the current entry[p923] of this.
2. If *current* is null, then throw an "InvalidStateError" DOMException.
3. Let *serializedState* be StructuredSerializeForStorage[p120](*options*["state[p922]"]), rethrowing any excpetions.
4. Set *current*'s session history entry[p927]'s navigation API state[p968] to *serializedState*.
5. Fire an event named currententrychange[p1406] at this using NavigationCurrentEntryChangeEvent[p949], with its navigationType[p949] attribute initialized to null and its from[p949] initialized to *current*.

The **canGoBack** getter steps are:

1. If this has entries and events disabled[p923], then return false.
2. Assert: this's current entry index[p923] is not −1.
3. If this's current entry index[p923] is 0, then return false.
4. Return true.

The **canGoForward** getter steps are:

1. If this has entries and events disabled[p923], then return false.
2. Assert: this's current entry index[p923] is not −1.
3. If this's current entry index[p923] is equal to this's entry list[p923]'s size, then return false.
4. Return true.

7.2.6.7 Initiating navigations §[p929]

For web developers (non-normative)

{ committed[p922], finished[p922] } = navigation[p922].navigate[p930](*url*)
{ committed[p922], finished[p922] } = navigation[p922].navigate[p930](*url*, *options*)

Navigates[p977] the current page to the given *url*. *options* can contain the following values:

- history[p922] can be set to "replace[p976]" to replace the current session history entry, instead of pushing a new one.
- info[p922] can be set to any value; it will populate the info[p941] property of the corresponding NavigateEvent[p939].
- state[p922] can be set to any serializable[p114] value; it will populate the state retrieved by navigation.currentEntry.getState()[p928] once the navigation completes, for same-document navigations. (It will be ignored for navigations that end up cross-document.)

By default this will perform a full navigation (i.e., a cross-document navigation, unless the given URL differs only in a fragment from the current one). The navigateEvent.intercept()[p941] method can be used to convert it into a same-document navigation.

The returned promises will behave as follows:

- For navigations that get aborted, both promises will reject with an "AbortError" DOMException.
- For same-document navigations created by using the navigateEvent.intercept()[p941] method, committed[p922] will fulfill immediately, and finished[p922] will fulfill or reject according to any promsies returned by handlers passed to intercept()[p941].
- For other same-document navigations (e.g., non-intercepted fragment navigations[p984]), both promises will fulfill immediately.
- For cross-document navigations, or navigations that result in 204 or 205 statuses or `Content-Disposition: attachment` header fields from the server (and thus do not actually navigate), both promises will never settle.

In all cases, when the returned promises fulfill, it will be with the NavigationHistoryEntry[p926] that was navigated to.

{ committed[p922], finished[p922] } = navigation[p922].reload[p931](*options*)

Reloads[p990] the current page. *options* can contain `info`[p922] and `state`[p922], which behave as described above.

The default behavior of performing a from-network-or-cache reload of the current page can be overriden by the using the `navigateEvent.intercept()`[p941] method. Doing so will mean this call only updates state or passes along the appropriate `info`[p922], plus performing whater actions the `navigate`[p1407] event handlers see fit to carry out.

The returned promises will behave as follows:

- If the reload is intercepted by using the `navigateEvent.intercept()`[p941] method, `committed`[p922] will fulfill immediately, and `finished`[p922] will fulfill or reject according to any promsies returned by handlers passed to `intercept()`[p941].
- Otherwise, both promises will never settle.

{ committed[p922], finished[p922] } = navigation[p922].traverseTo[p932](*key*)

{ committed[p922], finished[p922] } = navigation[p922].traverseTo[p932](*key*, { info[p922] })

Traverses[p1002] to the closest session history entry[p968] that matches the `NavigationHistoryEntry`[p926] with the given *key*. `info`[p922] can be set to any value; it will populate the `info`[p941] property of the corresponding `NavigateEvent`[p939].

If a traversal to that session history entry[p968] is already in progress, then this will return the promises for that original traversal, and `info`[p941] will be ignored.

The returned promises will behave as follows:

- If there is no `NavigationHistoryEntry`[p926] in `navigation.entries()`[p928] whose `key`[p927] matches *key*, both promises will reject with an `"InvalidStateError"` `DOMException`.
- For same-document traversals intercepted by the `navigateEvent.intercept()`[p941] method, `committed`[p922] will fulfill as soon as the traversal is processed and `navigation.currentEntry`[p928] is updated, and `finished`[p922] will fulfill or reject according to any promsies returned by the handlers passed to `intercept()`[p941].
- For non-intercepted same-document travesals, both promises will fulfill as soon as the traversal is processed and `navigation.currentEntry`[p928] is updated.
- For cross-document traversals, including attempted cross-document traversals that end up resulting in a 204 or 205 statuses or `` `Content-Disposition: attachment` `` header fields from the server (and thus do not actually traverse), both promises will never settle.

{ committed[p922], finished[p922] } = navigation[p922].back[p932](*key*)

{ committed[p922], finished[p922] } = navigation[p922].back[p932](*key*, { info[p922] })

Traverses to the closest previous session history entry[p968] which results in this navigable[p952] traversing, i.e., which corresponds to a different `NavigationHistoryEntry`[p926] and thus will cause `navigation.currentEntry`[p928] to change. `info`[p922] can be set to any value; it will populate the `info`[p941] property of the corresponding `NavigateEvent`[p939].

If a traversal to that session history entry[p968] is already in progress, then this will return the promises for that original traversal, and `info`[p941] will be ignored.

The returned promises behave equivalently to those returned by `traverseTo()`[p932].

{ committed[p922], finished[p922] } = navigation[p922].forward[p932](*key*)

{ committed[p922], finished[p922] } = navigation[p922].forward[p932](*key*, { info[p922] })

Traverses to the closest forward session history entry[p968] which results in this navigable[p952] traversing, i.e., which corresponds to a different `NavigationHistoryEntry`[p926] and thus will cause `navigation.currentEntry`[p928] to change. `info`[p922] can be set to any value; it will populate the `info`[p941] property of the corresponding `NavigateEvent`[p939].

If a traversal to that session history entry[p968] is already in progress, then this will return the promises for that original traversal, and `info`[p941] will be ignored.

The returned promises behave equivalently to those returned by `traverseTo()`[p932].

The **navigate(*options*)** method steps are:

1. Parse[p95] *url* relative to this's relevant settings object[p1039]. If that returns failure, then return an early error result[p933] for a `"SyntaxError"` `DOMException`. Otherwise, let *urlRecord* be the resulting URL record[p95].
2. Let *document* be this's relevant global object[p1039]'s associated `Document`[p894].

3. If *options*["history[p922]"] is "push[p976]", and the navigation must be a replace[p977] given *urlRecord* and *document*, then return an early error result[p933] for a "NotSupportedError" DOMException.

4. Let *state* be *options*["state[p922]"], if it exists; otherwise, undefined.

5. Let *serializedState* be StructuredSerializeForStorage[p120](*state*). If this throws an exception, then return an early error result[p933] for that exception.

   Note

   It is importantly to perform this step early, since serialization can invoke web developer code, which in turn might change various things we check in later steps.

6. If *document* is not fully active[p966], then return an early error result[p933] for an "InvalidStateError" DOMException.

7. If *document*'s unload counter[p1021] is greater than 0, then return an early error result[p933] for an "InvalidStateError" DOMException.

8. Let *info* be *options*["info[p922]"], if it exists; otherwise, undefined.

9. Let *apiMethodTracker* be the result of maybe setting the upcoming non-traverse API method tracker[p934] for this given *info* and *serializedState*.

10. Navigate[p977] *document*'s node navigable[p953] to *urlRecord* using *document*, with *historyHandling*[p977] set to *options*["history[p922]"] and *navigationAPIState*[p977] set to *serializedState*.

    Note

    Unlike location.assign()[p912] *and friends, which are exposed across origin-domain*[p870] *boundaries,* navigation.navigate()[p930] *can only be accessed by code with direct synchronous access to the* window.navigation[p922] *property. Thus, we avoid the complications about attributing the source document of the navigation, and we don't need to deal with the allowed by sandboxing to navigate*[p987] *check and its acccompanying* exceptionsEnabled[p977] *flag. We just treat all navigations as if they come from the* Document[p127] *corresponding to this* Navigation[p922] *object itself (i.e.,* document*).*

11. If this's upcoming non-traverse API method tracker[p934] is *apiMethodTracker*, then:

    Note

    If the upcoming non-traverse API method tracker[p934] *is still* apiMethodTracker*, this means that the navigate*[p977] *algorithm bailed out before ever getting to the inner* navigate *event firing algorithm*[p944] *which would promote that upcoming API method tracker to ongoing*[p936]*.*

    1. Set this's upcoming non-traverse API method tracker[p934] to null.

    2. Return an early error result[p933] for an "AbortError" DOMException.

12. Return a navigation API method tracker-derived result[p933] for *apiMethodTracker*.

The **reload(*options*)** method steps are:

1. Let *document* be this's relevant global object[p1039]'s associated Document[p894].

2. Let *serializedState* be StructuredSerializeForStorage[p120](undefined).

3. If *options*["state[p922]"] exists, then set *serializedState* to StructuredSerializeForStorage[p120](*options*["state[p922]"]). If this throws an exception, then return an early error result[p933] for that exception.

   Note

   It is importantly to perform this step early, since serialization can invoke web developer code, which in turn might change various things we check in later steps.

4. Otherwise:

   1. Let *current* be the current entry[p923] of this.

   2. If *current* is not null, then set *serializedState* to *current*'s session history entry[p927]'s navigation API state[p968].

5. If *document* is not fully active[p966], then return an early error result[p933] for an "InvalidStateError" DOMException.

6. If *document*'s unload counter[p1021] is greater than 0, then return an early error result[p933] for an "InvalidStateError" DOMException.

7. Let *info* be *options*["info[p922]"], if it exists; otherwise, undefined.

8. Let *apiMethodTracker* be the result of maybe setting the upcoming non-traverse API method tracker[p934] for this given *info* and *serializedState*.

9. Reload[p990] *document*'s node navigable[p953] with *navigationAPIState*[p990] set to *serializedState*.

10. Return a navigation API method tracker-derived result[p933] for *apiMethodTracker*.

The **traverseTo(*key*, *options*)** method steps are:

1. If this's current entry index[p923] is −1, then return an early error result[p933] for an "InvalidStateError" DOMException.

2. If this's entry list[p923] does not contain a NavigationHistoryEntry[p926] whose session history entry[p927]'s navigation API key[p968] equals *key*, then return an early error result[p933] for an "InvalidStateError" DOMException.

3. Return the result of performing a navigation API traversal[p932] given this, *key*, and *options*.

The **back(*options*)** method steps are:

1. If this's current entry index[p923] is −1 or 0, then return an early error result[p933] for an "InvalidStateError" DOMException.

2. Let *key* be this's entry list[p923][this's current entry index[p923] − 1]'s session history entry[p927]'s navigation API key[p968].

3. Return the result of performing a navigation API traversal[p932] given this, *key*, and *options*.

The **forward(*options*)** method steps are:

1. If this's current entry index[p923] is −1 or is equal to this's entry list[p923]'s size − 1, then return an early error result[p933] for an "InvalidStateError" DOMException.

2. Let *key* be this's entry list[p923][this's current entry index[p923] + 1]'s session history entry[p927]'s navigation API key[p968].

3. Return the result of performing a navigation API traversal[p932] given this, *key*, and *options*.

To **perform a navigation API traversal** given a Navigation[p922] *navigation*, a string *key*, and a NavigationOptions[p922] *options*:

1. Let *document* be *navigation*'s relevant global object[p1039]'s associated Document[p894].

2. If *document* is not fully active[p966], then return an early error result[p933] for an "InvalidStateError" DOMException.

3. If *document*'s unload counter[p1021] is greater than 0, then return an early error result[p933] for an "InvalidStateError" DOMException.

4. Let *current* be the current entry[p923] of *navigation*.

5. If *key* equals *current*'s session history entry[p927]'s navigation API key[p968], then return «["committed[p922]" → a promise resolved with *current*, "finished[p922]" → a promise resolved with *current*]».

6. If *navigation*'s upcoming traverse API method trackers[p934][*key*] exists, then return a navigation API method tracker-derived result[p933] for *navigation*'s upcoming traverse API method trackers[p934][*key*].

7. Let *info* be *options*["info[p922]"], if it exists; otherwise, undefined.

8. Let *apiMethodTracker* be the result of adding an upcoming traverse API method tracker[p935] for *navigation* given *key* and *info*.

9. Let *navigable* be *document*'s node navigable[p953].

10. Let *traversable* be *navigable*'s traversable navigable[p953].

11. Let *sourceSnapshotParams* be the result of snapshotting source snapshot params[p975] given *document*.

12. Append the following session history traversal steps[p971] to *traversable*:

    1. Let *navigableSHEs* be the result of getting session history entries[p973] given *navigable*.

    2. Let *targetSHE* be the session history entry[p968] in *navigableSHEs* whose navigation API key[p968] is *key*. If no such

entry exists, then:

1. Queue a global task[p1073] on the navigation and traversal task source[p1081] given *navigation*'s relevant global object[p1039] to reject the finished promise[p937] for *apiMethodTracker* with an "InvalidStateError" DOMException.

2. Abort these steps.

Note

This path is taken if navigation's *entry list[p923] was outdated compared to* navigableSHEs*, which can occur for brief periods while all the relevant threads and processes are being synchronized in reaction to a history change.*

3. If *targetSHE* is *navigable*'s active session history entry[p952], then abort these steps.

Note

This can occur if a previously queued[p971] traversal already took us to this session history entry[p968]. In that case the previous traversal will have dealt with apiMethodTracker *already.*

4. Let *result* be the result of applying the traverse history step[p1002] given by *targetSHE*'s step[p968] to *traversable*, given *sourceSnapshotParams*, *navigable*, and "none[p977]".

5. If *result* is "canceled-by-beforeunload", then queue a global task[p1073] on the navigation and traversal task source[p1081] given *navigation*'s relevant global object[p1039] to reject the finished promise[p937] for *apiMethodTracker* with a new "AbortError" DOMException created in *navigation*'s relevant realm[p1039].

6. If *result* is "initiator-disallowed", then queue a global task[p1073] on the navigation and traversal task source[p1081] given *navigation*'s relevant global object[p1039] to reject the finished promise[p937] for *apiMethodTracker* with a new "SecurityError" DOMException created in *navigation*'s relevant realm[p1039].

Note

When result *is* "canceled-by-beforeunload" *or* "initiator-disallowed"*, the* navigate[p1407] *event was never fired, aborting the ongoing navigation[p937] would not be correct; it would result in a* navigateerror[p1407] *event without a preceding* navigate[p1407] *event.*

In the "canceled-by-navigate" *case,* navigate[p1407] *is fired, but the inner* navigate *event firing algorithm[p944] will take care of aborting the ongoing navigation[p937].*

13. Return a navigation API method tracker-derived result[p933] for *apiMethodTracker*.

An **early error result** for an exception *e* is a NavigationResult[p922] dictionary instance given by «["committed[p922]" → a promise rejected with *e*, "finished[p922]" → a promise rejected with *e*]».

A **navigation API method tracker-derived result** for a navigation API method tracker[p934] is a NavigationResult[p922] dictionary instance given by «["committed[p922]" *apiMethodTracker*'s committed promise[p934], "finished[p922]" → *apiMethodTracker*'s finished promise[p934]]».

7.2.6.8 Ongoing navigation tracking §[p933]

During any given navigation (in the broad sense of the word[p923]), the Navigation[p922] object needs to keep track of the following:

For all navigations

State	Duration	Explanation
The NavigateEvent[p939]	For the duration of event firing	So that if the navigation is canceled while the event is firing, we can cancel the event
The event's abort controller[p941]	Until all promises returned from handlers passed to intercept()[p941] have settled	So that if the navigation is canceled, we can signal abort
Whether a new element was focused[p822]	Until all promises returned from handlers passed to intercept()[p941] have settled	So that if one was, focus is not reset[p948]
The NavigationHistoryEntry[p926] being navigated to	From when it is determined, until all promises returned from handlers passed to intercept()[p941] have settled	So that we know what to resolve any committed[p922] and finished[p922] promises with
Any finished[p922] promise that	Until all promises returned from handlers passed to intercept()[p941]	So that we can resolve or reject it appropriately

State	Duration	Explanation
was returned	have settled	

For non-"traverse[p924]" navigations

State	Duration	Explanation
Any state[p922]	For the duration of event firing	So that we can update the current entry's navigation API state[p968] if the event finishes firing without being canceled

For "traverse[p924]" navigations

State	Duration	Explanation
Any info[p922]	Until the task is queued to fire the navigate[p1407] event	So that we can use it to fire the navigate[p1407] after the trip through the session history traversal queue[p953].
Any committed[p922] promise that was returned	Until the session history is updated (inside that same task)	So that we can resolve or reject it appropriately
Whether intercept()[p941] was called	Until the session history is updated (inside that same task)	So that we can suppress the normal scroll restoration logic in favor of the behavior given by the scroll[p939] option

We also cannot assume there is only a single navigation requested at any given time, due to web developer code such as:

```
const p1 = navigation.navigate(url1).finished;
const p2 = navigation.navigate(url2).finished;
```

That is, in this scenario, we need to ensure that while navigating to `url2`, we still have the promise `p1` around so that we can reject it. We can't just get rid of any ongoing navigation promises the moment the second call to navigate()[p930] happens.

We end up accomplishing all this by associating the following with each Navigation[p922]:

- **Ongoing navigate event**, a NavigateEvent[p939] or null, initially null.
- **Focus changed during ongoing navigation**, a boolean, initially false.
- **Suppress normal scroll restoration during ongoing navigation**, a boolean, initially false.
- **Ongoing API method tracker**, a navigation API method tracker[p934] or null, initially null.
- **Upcoming non-traverse API method tracker**, a navigation API method tracker[p934] or null, initially null.
- **Upcoming traverse API method trackers**, a map[p461] from strings to navigation API method trackers[p934], initially empty.

Note

The state here that is not stored in navigation API method trackers[p934] is state which needs to be tracked even for navigations that are not initiated via navigation API methods.

A **navigation API method tracker** is a struct with the following items:

- A **navigation object**, a Navigation[p922]
- A **key**, a string or null
- An **info**, a JavaScript value
- A **serialized state**, a serialized state[p968] or null
- A **committed-to entry**, a NavigationHistoryEntry[p926] or null
- A **committed promise**, a promise
- A **finished promise**, a promise

All this state is then managed via the following algorithms.

To **maybe set the upcoming non-traverse API method tracker** given a Navigation[p922] *navigation*, a JavaScript value *info*, and a serialized state[p968]-or-null *serializedState*:

1. Let *committedPromise* and *finishedPromise* be new promises created in *navigation*'s relevant realm[p1039].

2. Mark as handled *finishedPromise*.

> **Note**
> *The web developer doesn't necessarily care about* finishedPromise *being rejected:*
>
> - *They might only care about* committedPromise.
> - *They could be doing multiple synchronous navigations within the same task, in which case all but the last will be aborted (causing their* finishedPromise *to reject). This could be an application bug, but also could just be an emergent feature of disparate parts of the application overriding each others' actions.*
> - *They might prefer to listen to other transition-failure signals instead of* finishedPromise*, e.g., the* `navigateerror`[p1407] *event, or the* `navigation.transition.finished`[p939] *promise.*
>
> *As such, we mark it as handled to ensure that it never triggers* `unhandledrejection`[p1407] *events.*

3. Let *apiMethodTracker* be a new navigation API method tracker[p934] with:

   navigation object[p934]
   navigation
   key[p934]
   null
   info[p934]
   info
   serialized state[p934]
   serializedState
   comitted-to entry[p934]
   null
   comitted promise[p934]
   committedPromise
   finished promise[p934]
   finishedPromise

4. Assert: *navigation*'s upcoming non-traverse API method tracker[p934] is null.

5. If *navigation* does not have entries and events disabled[p923], then set *navigation*'s upcoming non-traverse API method tracker[p934] to *apiMethodTracker*.

> **Note**
> *If* navigation *has entries and events disabled*[p923]*, then* committedPromise *and* finishedPromise *will never fulfill (since we never create a* `NavigationHistoryEntry`[p926] *object for such* `Document`[p127]*s, and so we have nothing to resolve them with); there is no* `NavigationHistoryEntry`[p926] *to apply* serializedState *to; and there is no* `navigate`[p1407] *event to include* info *with. So, we don't need to track this API method call after all.*

6. Return *apiMethodTracker*.

To **add an upcoming traverse API method tracker** given a `Navigation`[p922] *navigation*, a string *destinationKey*, and a JavaScript value *info*:

1. Let *committedPromise* and *finishedPromise* be new promises created in *navigation*'s relevant realm[p1039].

2. Mark as handled *finishedPromise*.

> **Note**
> *See the previous discussion*[p935] *about why this is done.*

3. Let *apiMethodTracker* be a new navigation API method tracker[p934] with:

   navigation object[p934]
   navigation
   key[p934]
   destinationKey
   info[p934]
   info

serialized state[p934]
null
comitted-to entry[p934]
null
comitted promise[p934]
committedPromise
finished promise[p934]
finishedPromise

4. Set *navigation*'s upcoming traverse API method trackers[p934][*key*] to *apiMethodTracker*.

5. Return *apiMethodTracker*.

To **promote an upcoming API method tracker to ongoing** given a `Navigation`[p922] *navigation* and a string-or-null *destinationKey*:

1. Assert: *navigation*'s ongoing API method tracker[p934] is null.

2. If *destinationKey* is not null, then:

    1. Assert: *navigation*'s upcoming non-traverse API method tracker[p934] is null.

    2. If *navigation*'s upcoming traverse API method trackers[p934][*destinationKey*] exists, then:

        1. Set *navigation*'s ongoing API method tracker[p934] to *navigation*'s upcoming traverse API method trackers[p934][*destinationKey*].

        2. Remove *navigation*'s upcoming traverse API method trackers[p934][*destinationKey*].

3. Otherwise:

    1. Set *navigation*'s ongoing API method tracker[p934] to *navigation*'s upcoming non-traverse API method tracker[p934].

    2. Set *navigation*'s upcoming non-traverse API method tracker[p934] to null.

To **clean up** a navigation API method tracker[p934] *apiMethodTracker*:

1. Let *navigation* be *apiMethodTracker*'s navigation object[p934].

2. If *navigation*'s ongoing API method tracker[p934] is *apiMethodTracker*, then set *navigation*'s ongoing API method tracker[p934] to null.

3. Otherwise:

    1. Let *key* be *apiMethodTracker*'s key[p934].

    2. Assert: *key* is not null.

    3. Assert: *navigation*'s upcoming traverse API method trackers[p934][*key*] exists.

    4. Remove *navigation*'s upcoming traverse API method trackers[p934][*key*].

To **notify about the committed-to entry** given a navigation API method tracker[p934] *apiMethodTracker* and a `NavigationHistoryEntry`[p926] *nhe*:

1. Set *apiMethodTracker*'s committed-to entry[p934] to *nhe*.

2. If *apiMethodTracker*'s serialized state[p934] is not null, then set *nhe*'s session history entry[p927]'s navigation API state[p968] to *apiMethodTracker*'s serialized state[p934].

    Note
    If it's null, then we're traversing to nhe *via* `navigation.traverseTo()`[p932]*, which does not allow changing the state.*

    Note
    At this point, apiMethodTracker's *serialized state*[p934] *is no longer needed. Implementations might want to clear it out to avoid keeping it alive for the lifetime of the navigation API method tracker*[p934]*.*

3. Resolve *apiMethodTracker*'s committed promise[p934] with *nhe*.

> **Note**
> *At this point,* apiMethodTracker's *committed promise*[p934] *is only needed in cases where it has not yet been returned to author code. Implementations might want to clear it out to avoid keeping it alive for the lifetime of the navigation API method tracker*[p934].

To **resolve the finished promise** for a navigation API method tracker[p934] *apiMethodTracker*:

1. Resolve *apiMethodTracker*'s committed promise[p934] with its committed-to entry[p934].

   > **Note**
   > *Usually, notify about the committed-to entry*[p936] *has previously been called on* apiMethodTracker, *and so this will do nothing. However, in some cases resolve the finished promise*[p937] *is called directly, in which case this step is necessary.*

2. Resolve *apiMethodTracker*'s finished promise[p934] with its committed-to entry[p934].
3. Clean up[p936] *apiMethodTracker*.

To **reject the finished promise** for a navigation API method tracker[p934] *apiMethodTracker* with a JavaScript value *exception*:

1. Reject *apiMethodTracker*'s committed promise[p934] with *exception*.

   > **Note**
   > *This will do nothing if* apiMethodTracker's *committed promise*[p934] *was previously resolved via notify about the committed-to entry*[p936].

2. Reject *apiMethodTracker*'s finished promise[p934] with *exception*.
3. Clean up[p936] *apiMethodTracker*.

To **abort the ongoing navigation** given a `Navigation`[p922] *navigation* and an optional `DOMException` *error*:

1. Let *event* be *navigation*'s ongoing `navigate` event[p934].
2. Assert: *event* is not null.
3. Set *navigation*'s focus changed during ongoing navigation[p934] to false.
4. Set *navigation*'s suppress normal scroll restoration during ongoing navigation[p934] to false.
5. If *error* was not given, then let *error* be a new `"AbortError"` `DOMException` created in *navigation*'s relevant realm[p1039].
6. If *event*'s dispatch flag is set, then set *event*'s canceled flag to true.
7. Signal abort on *event*'s abort controller[p941] given *error*.
8. Set *navigation*'s ongoing `navigate` event[p934] to null.
9. Fire an event named `navigateerror`[p1407] at *navigation* using `ErrorEvent`[p1054], with `error`[p1054] initialized to *error*, and `message`[p1054], `filename`[p1054], `lineno`[p1054], and `colno`[p1054] initialized to appropriate values that can be extracted from *error* and the current JavaScript stack in the same underspecified way that the report the exception[p1053] algorithm does.

   > **Note**
   > *Thus, for example, if this algorithm is reached because of a call to* `window.stop()`[p898]*, these properties would probably end up initialized based on the line of script that called* `window.stop()`[p898]*. But if it's because the user clicked the stop button, these properties would probably end up with default values like the empty string or 0.*

10. If *navigation*'s ongoing API method tracker[p934] is non-null, then reject the finished promise[p937] for *apiMethodTracker* with *error*.
11. If *navigation*'s transition[p938] is not null, then:
    1. Reject *navigation*'s transition[p938]'s finished promise[p938] with *error*.
    2. Set *navigation*'s transition[p938] to null.

To **inform the navigation API about aborting navigation** in a navigable[p952] *navigable*:

1. If this algorithm is running on *navigable*'s active window[p952]'s relevant agent[p1029]'s event loop[p1071], then continue on to the following steps. Otherwise, queue a global task[p1073] on the navigation and traversal task source[p1081] given *navigable*'s active window[p952] to run the following steps.
2. Let *navigation* be *navigable*'s active window[p952]'s navigation API[p922].
3. If *navigation*'s ongoing navigate event[p934] is null, then return.
4. Abort the ongoing navigation[p937] given *navigation*.

To **inform the navigation API about child navigable destruction** given a navigable[p952] *navigable*:

1. Inform the navigation API about aborting navigation[p937] in *navigable*.
2. Let *navigation* be *navigable*'s active window[p952]'s navigation API[p922].
3. Let *traversalAPIMethodTrackers* to be clone of *navigation*'s upcoming traverse API method trackers[p934].
4. For each *apiMethodTracker* of *traversalAPIMethodTrackers*: reject the finished promise[p937] for *apiMethodTracker* with a new `"AbortError"` `DOMException` created in *navigation*'s relevant realm[p1039].

The ongoing navigation concept is most-directly exposed to web developers through the `navigation.transition`[p938] property, which is an instance of the `NavigationTransition`[p938] interface:

IDL
```
[Exposed=Window]
interface NavigationTransition {
  readonly attribute NavigationType navigationType;
  readonly attribute NavigationHistoryEntry from;
  readonly attribute Promise<undefined> finished;
};
```

For web developers (non-normative)

`navigation`[p922]`.transition`[p938]

A `NavigationTransition`[p938] representing any ongoing navigation that hasn't yet reached the `navigatesuccess`[p1407] or `navigateerror`[p1407] stage, if one exists; or null, if there is no such transition ongoing.

Since `navigation.currentEntry`[p928] (and other properties like `location.href`[p909]) are updated immediately upon navigation, this `navigation.transition`[p938] property is useful for determining when such navigations are not yet fully settled, according to any handlers passed to `navigateEvent.intercept()`[p941].

`navigation`[p922]`.transition`[p938]`.navigationType`[p938]

One of "`push`[p923]", "`replace`[p923]", "`reload`[p924]", or "`traverse`[p924]", indicating what type of navigation this transition is for.

`navigation`[p922]`.transition`[p938]`.from`[p938]

The `NavigationHistoryEntry`[p926] from which the transition is coming. This can be useful to compare against `navigation.currentEntry`[p928].

`navigation`[p922]`.transition`[p938]`.finished`[p939]

A promise which fulfills at the same time as the `navigatesuccess`[p1407] fires, or rejects at the same time the `navigateerror`[p1407] event fires.

Each `Navigation`[p922] has a **transition**, which is a `NavigationTransition`[p938] or null, initially null.

The **`transition`** getter steps are to return this's transition[p938].

Each `NavigationTransition`[p938] has an associated **navigation type**, which is a `NavigationType`[p923].

Each `NavigationTransition`[p938] has an associated **from entry**, which is a `NavigationHistoryEntry`[p926].

Each `NavigationTransition`[p938] has an associated **finished promise**, which is a promise.

The **`navigationType`** getter steps are to return this's navigation type[p938].

The **`from`** getter steps are to return this's from entry[p938].

The **finished** getter steps are to return this's finished promise[p938].

7.2.6.9 The navigate[p1407] event §[p939]

A major feature of the navigation API is the navigate[p1407] event. This event is fired on any navigation (in the broad sense of the word[p923]), allowing web developers to monitor such outgoing navigations. In many cases, the event is cancelable, which allows preventing the navigation from happening. And in others, the navigation can be intercepted and replaced with a same-document navigation by using the intercept()[p941] method of the NavigateEvent[p939] class.

7.2.6.9.1 The NavigateEvent[p939] interface §[p939]

IDL

```
[Exposed=Window]
interface NavigateEvent : Event {
  constructor(DOMString type, NavigateEventInit eventInitDict);

  readonly attribute NavigationType navigationType;
  readonly attribute NavigationDestination destination;
  readonly attribute boolean canIntercept;
  readonly attribute boolean userInitiated;
  readonly attribute boolean hashChange;
  readonly attribute AbortSignal signal;
  readonly attribute FormData? formData;
  readonly attribute DOMString? downloadRequest;
  readonly attribute any info;

  undefined intercept(optional NavigationInterceptOptions options = {});
  undefined scroll();
};

dictionary NavigateEventInit : EventInit {
  NavigationType navigationType = "push";
  required NavigationDestination destination;
  boolean canIntercept = false;
  boolean userInitiated = false;
  boolean hashChange = false;
  required AbortSignal signal;
  FormData? formData = null;
  DOMString? downloadRequest = null;
  any info;
};

dictionary NavigationInterceptOptions {
  NavigationInterceptHandler handler;
  NavigationFocusReset focusReset;
  NavigationScrollBehavior scroll;
};

enum NavigationFocusReset {
  "after-transition",
  "manual"
};

enum NavigationScrollBehavior {
  "after-transition",
  "manual"
};

callback NavigationInterceptHandler = Promise<undefined> ();
```

For web developers (non-normative)

***event*.navigationType**[p941]

One of "push[p923]", "replace[p923]", "reload[p924]", or "traverse[p924]", indicating what type of navigation this is.

***event*.destination**[p941]

A NavigationDestination[p942] representing the destination of the navigation.

***event*.canIntercept**[p941]

True if intercept()[p941] can be called to intercept this navigation and convert it into a same-document navigation, replacing its usual behavior; false otherwise.

Generally speaking, this will be true whenever the current Document[p127] can have its URL rewritten[p917] to the destination URL, except for in the case of cross-document "traverse[p924]" navigations, where it will always be false.

***event*.userInitiated**[p941]

True if this navigation was due to a user clicking on an a[p252] element, submitting a form[p505] element, or using the browser UI[p1026] to navigate; false otherwise.

***event*.hashChange**[p941]

True for a fragment navigation[p984]; false otherwise.

***event*.signal**[p941]

An AbortSignal which will become aborted if the navigation gets canceled, e.g., by the user pressing their browser's "Stop" button, or by another navigation interrupting this one.

The expected pattern is for developers to pass this along to any async operations, such as fetch(), which they perform as part of handling this navigation.

***event*.formData**[p941]

The FormData representing the submitted form entries for this navigation, if this navigation is a "push[p923]" or "replace[p923]" navigation representing a POST form submission[p619]; null otherwise.

(Notably, this will be null even for "reload[p924]" or "traverse[p924]" navigations that are revisiting a session history entry[p968] that was originally created from a form submission.)

***event*.downloadRequest**[p941]

Represents whether or not this navigation was requested to be a download, by using an a[p252] or area[p463] element's download[p297] attribute:

- If a download was not requested, then this property is null.
- If a download was requested, returns the filename that was supplied as the download[p297] attribute's value. (This could be the empty string.)

Note that a download being requested does not always mean that a download will happen: for example, a download might be blocked by browser security policies, or end up being treated as a "push[p976]" navigation for unspecified reasons.

Similarly, a navigation might end up being a download even if it was not requested to be one, due to the destination server responding with a `Content-Disposition: attachment` header.

Finally, note that the navigate[p1407] event will not fire at all for downloads initiated using browser UI affordances, e.g., those created by right-clicking and choosing to save the target of a link.

***event*.info**[p941]

An arbitrary JavaScript value passed via one of the navigation API methods[p929] which initiated this navigation, or undefined if the navigation was initiated by the user or by a different API.

***event*.intercept**[p941]**({ handler**[p939]**, focusReset**[p939]**, scroll**[p939]**})**

Intercepts this navigation, preventing its normal handling and instead converting it into a same-document navigation of the same type to the destination URL.

The handler[p939] option can be a function that returns a promise. The handler function will run after the navigate[p1407] event has finished firing, and the navigation.currentEntry[p928] property has been synchronously updated. This returned promise is used to signal the duration, and success or failure, of the navigation. After it settles, the browser signals to the user (e.g., via a loading spinner UI, or assistive technology) that the navigation is finished. Additionally, it fires navigatesuccess[p1407] or navigateerror[p1407] events as appropriate, which other parts of the web application can respond to.

By default, using this method will cause focus to reset when any handlers' returned promises settle. Focus will be reset to the first element with the autofocus[p828] attribute set, or the body element[p133] if the attribute isn't present. The focusReset[p939] option can be set to "manual[p939]" to avoid this behavior.

By default, using this method will delay the browser's scroll restoration logic for "traverse[p924]" or "reload[p924]" navigations, or its scroll-reset/scroll-to-a-fragment logic for "push[p923]" or "replace[p923]" navigations, until any handlers' returned promises settle. The scroll[p939] option can be set to "manual[p939]" to turn off any browser-driven scroll behavior entirely for this navigation, or scroll()[p941] can be called before the promise settles to trigger this behavior early.

This method will throw a "SecurityError" DOMException if canIntercept[p941] is false, or if isTrusted is false. It will throw an "InvalidStateError" DOMException if not called synchronously, during event dispatch.

***event*.scroll[p941]()**

For "traverse[p924]" or "reload[p924]" navigations, restores the scroll position using the browser's usual scroll restoration logic.

For "push[p923]" or "replace[p923]" navigations, either resets the scroll position to the top of the document or scrolls to the fragment specified by destination.url[p943] if there is one.

If called more than once, or called after automatic post-transition scroll processing has happened due to the scroll[p939] option being left as "after-transition[p939]", or called before the navigation has committed, this method will throw an "InvalidStateError" DOMException.

Each NavigateEvent[p939] has an **interception state**, which is either "none", "intercepted", "committed", "scrolled", or "finished", initially "none".

Each NavigateEvent[p939] has a **navigation handler list**, a list of NavigationInterceptHandler[p939] callbacks, initially empty.

Each NavigateEvent[p939] has a **focus reset behavior**, a NavigationFocusReset[p939]-or-null, initially null.

Each NavigateEvent[p939] has a **scroll behavior**, a NavigationScrollBehavior[p939]-or-null, initially null.

Each NavigateEvent[p939] has an **abort controller**, an AbortController-or-null, initially null.

Each NavigateEvent[p939] has a **classic history API state**, a serialized state[p968] or null. It is only used in some cases where the event's navigationType[p941] is "push[p923]" or "replace[p923]", and is set appropriately when the event is fired.

The **navigationType**, **destination**, **canIntercept**, **userInitiated**, **hashChange**, **signal**, **formData**, **downloadRequest**, and **info** attributes must return the values they are initialized to.

The **intercept(*options*)** method steps are:

1. Perform shared checks[p942] given this.
2. If this's canIntercept[p941] attribute was initialized to false, then throw a "SecurityError" DOMException.
3. If this's dispatch flag is unset, then throw an "InvalidStateError" DOMException.
4. Assert: this's interception state[p941] is either "none" or "intercepted".
5. Set this's interception state[p941] to "intercepted".
6. If *options*["handler[p939]"] exists, then append it to this's navigation handler list[p941].
7. If *options*["focusReset[p939]"] exists, then:
    1. If this's focus reset behavior[p941] is not null, and it is not equal to *options*["focusReset[p939]"], then the user agent may report a warning to the console indicating that the focusReset[p939] option for a previous call to intercept()[p941] was overridden by this new value, and the previous value will be ignored.
    2. Set this's focus reset behavior[p941] to *options*["focusReset[p939]"].
8. If *options*["scroll[p939]"] exists, then:
    1. If this's scroll behavior[p941] is not null, and it is not equal to *options*["scroll[p939]"], then the user agent may report a warning to the console indicating that the scroll[p939] option for a previous call to intercept()[p941] was overridden by this new value, and the previous value will be ignored.
    2. Set this's scroll behavior[p941] to *options*["scroll[p939]"].

The **scroll()** method steps are:

1. Perform shared checks[p942] given this.
2. If this's interception state[p941] is not "committed", then throw an "InvalidStateError" DOMException.
3. Process scroll behavior[p949] given this.

To **perform shared checks** for a NavigateEvent[p939] *event*:

1. If *event*'s relevant global object[p1039]'s associated Document[p894] is not fully active[p966], then throw an "InvalidStateError" DOMException.
2. If *event*'s isTrusted attribute was initialized to false, then throw a "SecurityError" DOMException.
3. If *event*'s canceled flag is set, then throw an "InvalidStateError" DOMException.

7.2.6.9.2 The NavigationDestination[p942] interface §[p942]

IDL
```
[Exposed=Window]
interface NavigationDestination {
  readonly attribute USVString url;
  readonly attribute DOMString key;
  readonly attribute DOMString id;
  readonly attribute long long index;
  readonly attribute boolean sameDocument;

  any getState();
};
```

For web developers (non-normative)

***event*.destination[p941].url[p943]**

The URL being navigated to.

***event*.destination[p941].key[p943]**

The value of the key[p927] property of the destination NavigationHistoryEntry[p926], if this is a "traverse[p924]" navigation, or the empty string otherwise.

***event*.destination[p941].id[p943]**

The value of the id[p927] property of the destination NavigationHistoryEntry[p926], if this is a "traverse[p924]" navigation, or the empty string otherwise.

***event*.destination[p941].index[p943]**

The value of the index[p927] property of the destination NavigationHistoryEntry[p926], if this is a "traverse[p924]" navigation, or −1 otherwise.

***event*.destination[p941].sameDocument[p943]**

Indicates whether or not this navigation is to the same Document[p127] as the current one, or not. This will be true, for example, in the case of fragment navigations or history.pushState()[p917] navigations.

Note that this property indicates the original nature of the navigation. If a cross-document navigation is converted into a same-document navigation using navigateEvent.intercept()[p941], that will not change the value of this property.

***event*.destination[p941].getState[p943]()**

For "traverse[p924]" navigations, returns the deserialization[p120] of the state stored in the destination session history entry[p968].

For "push[p923]" or "replace[p923]" navigations, returns the deserialization[p120] of the state passed to navigation.navigate()[p930], if the navigation was initiated by that method, or undefined it if it wasn't.

For "reload[p924]" navigations, returns the deserialization[p120] of the state passed to navigation.reload()[p931], if the reload was initiated by that method, or undefined it if it wasn't.

Each NavigationDestination[p942] has a **URL**, which is a URL.

Each NavigationDestination[p942] has an **entry**, which is a NavigationHistoryEntry[p926] or null.

Note

It will be non-null if and only if the NavigationDestination[p942] corresponds to a "traverse[p924]" navigation.

Each NavigationDestination[p942] has a **state**, which is a serialized state[p968].

Each NavigationDestination[p942] has an **is same document**, which is a boolean.

The **url** getter steps are to return this's URL[p942], serialized.

The **key** getter steps are:

1. If this's entry[p942] is null, then return the empty string.
2. Return this's entry[p942]'s key[p927].

The **id** getter steps are:

1. If this's entry[p942] is null, then return the empty string.
2. Return this's entry[p942]'s ID[p927].

The **index** getter steps are:

1. If this's entry[p942] is null, then return −1.
2. Return this's entry[p942]'s index[p927].

The **sameDocument** getter steps are to return this's is same document[p943].

The **getState()** method steps are to return StructuredDeserialize[p120](this's state[p943]).

7.2.6.9.3 Firing the event §[p943]

Other parts of the standard fire the navigate[p1407] event, through a series of wrapper algorithms given in this section.

To **fire a traverse navigate event** at a Navigation[p922] *navigation* given a session history entry[p968] ***destinationSHE*** and an optional user navigation involvement[p977] ***userInvolvement*** (default "none[p977]"):

1. Let *event* be the result of creating an event given NavigateEvent[p939], in *navigation*'s relevant realm[p1039].
2. Set *event*'s classic history API state[p941] to null.
3. Let *destination* be a new NavigationDestination[p942] created in *navigation*'s relevant realm[p1039].
4. Set *destination*'s URL[p942] to *destinationSHE*'s URL[p968].
5. Let *destinationNHE* be the NavigationHistoryEntry[p926] in *navigation*'s entry list[p923] whose session history entry[p927] is *destinationSHE*, or null if no such NavigationHistoryEntry[p926] exists.
6. If *destinationNHE* is non-null, then:
    1. Set *destination*'s entry[p942] to *destinationNHE*.
    2. Set *destination*'s state[p943] to *destinationSHE*'s navigation API state[p968].
7. Otherwise,
    1. Set *destination*'s entry[p942] to null.
    2. Set *destination*'s state[p943] to StructuredSerializeForStorage[p120](null).
8. Set *destination*'s is same document[p943] to true if *destinationSHE*'s document[p968] is equal to *navigation*'s relevant global object[p1039]'s associated Document[p894]; otherwise false.
9. Return the result of performing the inner navigate event firing algorithm[p944] given *navigation*, "traverse[p924]", *event*,

destination, *userInvolvement*, null, and null.

To **fire a push/replace/reload navigate event** at a Navigation[p922] *navigation* given a NavigationType[p923] ***navigationType***, a URL ***destinationURL***, a boolean ***isSameDocument***, an optional user navigation involvement[p977] ***userInvolvement*** (default "none[p977]"), an optional entry list[p622]-or-null ***formDataEntryList*** (default null), an optional serialized state[p968] ***navigationAPIState*** (default StructuredSerializeForStorage[p120](null)), and an optional serialized state[p968]-or-null ***classicHistoryAPIState*** (default null):

1. Let *event* be the result of creating an event given NavigateEvent[p939], in *navigation*'s relevant realm[p1039].
2. Set *event*'s classic history API state[p941] to *classicHistoryAPIState*.
3. Let *destination* be a new NavigationDestination[p942] created in *navigation*'s relevant realm[p1039].
4. Set *destination*'s URL[p942] to *destinationURL*.
5. Set *destination*'s entry[p942] to null.
6. Set *destination*'s state[p943] to *navigationAPIState*.
7. Set *destination*'s is same document[p943] to *isSameDocument*.
8. Return the result of performing the inner navigate event firing algorithm[p944] given *navigation*, *navigationType*, *event*, *destination*, *userInvolvement*, *formDataEntryList*, and null.

To **fire a download request navigate event** at a Navigation[p922] *navigation* given a URL ***destinationURL***, a user navigation involvement[p977] ***userInvolvement***, and a string ***filename***:

1. Let *event* be the result of creating an event given NavigateEvent[p939], in *navigation*'s relevant realm[p1039].
2. Set *event*'s classic history API state[p941] to null.
3. Let *destination* be a new NavigationDestination[p942] created in *navigation*'s relevant realm[p1039].
4. Set *destination*'s URL[p942] to *destinationURL*.
5. Set *destination*'s entry[p942] to null.
6. Set *destination*'s state[p943] to StructuredSerializeForStorage[p120](null).
7. Set *destination*'s is same document[p943] to false.
8. Return the result of performing the inner navigate event firing algorithm[p944] given *navigation*, "push[p923]", *event*, *destination*, *userInvolvement*, null, and *filename*.

The **inner navigate event firing algorithm** consists of the following steps, given a Navigation[p922] *navigation*, a NavigationType[p923] *navigationType*, a NavigateEvent[p939] *event*, a NavigationDestination[p942] *destination*, a user navigation involvement[p977] *userInvolvement*, an entry list[p622]-or-null *formDataEntryList*, and a string-or-null *downloadRequestFilename*:

1. If *navigation* has entries and events disabled[p923], then:
    1. Assert: *navigation*'s ongoing API method tracker[p934] is null.
    2. Assert: *navigation*'s upcoming non-traverse API method tracker[p934] is null.
    3. Assert: *navigation*'s upcoming traverse API method trackers[p934] is empty.
    4. Return true.

    Note

    These assertions holds because traverseTo()[p932], back()[p932], and forward()[p932] will immediately fail when entries and events are disabled (since there are no entries to traverse to), and if our starting point is instead navigate()[p930] or reload()[p931], then we avoided[p935] setting the upcoming non-traverse API method tracker[p934] in the first place.

2. Let *destinationKey* be null.
3. If *destination*'s entry[p942] is non-null, then set *destinationKey* to *destination*'s entry[p942]'s key[p927].
4. Assert: *destinationKey* is not the empty string.

5. Promote an upcoming API method tracker to ongoing[p936] given *navigation* and *destinationKey*.

6. Let *apiMethodTracker* be *navigation*'s ongoing API method tracker[p934].

7. Let *navigable* be *navigation*'s relevant global object[p1039]'s navigable[p894].

8. Let *document* be *navigation*'s relevant global object[p1039]'s associated `Document`[p894].

9. If *document* can have its URL rewritten[p917] to *destination*'s URL[p942], and either *destination*'s is same document[p943] is true or *navigationType* is not "`traverse`[p924]", then initialize *event*'s `canIntercept`[p941] to true. Otherwise, initialize it to false.

10. Let *traverseCanBeCanceled* be true if all of the following are true:

    - *navigable* is a top-level traversable[p953];
    - *destination*'s is same document[p943] is true; and
    - either *userInvolvement* is not "`browser UI`[p977]", or *navigation*'s relevant global object[p1039] has transient activation[p811].

    Otherwise, let it be false.

11. If either:

    - *navigationType* is not "`traverse`[p924]"; or
    - *traverseCanBeCanceled* is true

    the initialize *event*'s `cancelable` to true. Otherwise, initialize it to false.

12. Initialize *event*'s `type` to "`navigate`[p1407]".

13. Initialize *event*'s `navigationType`[p941] to *navigationType*.

14. Initialize *event*'s `destination`[p941] to *destination*.

15. Initialize *event*'s `downloadRequest`[p941] to *downloadRequestFilename*.

16. If *apiMethodTracker* is not null, then initialize *event*'s `info`[p941] to *apiMethodTracker*'s info[p934]. Otherwise, initialize it to undefined.

    Note

    At this point apiMethodTracker's *info*[p934] *is no longer needed and can be nulled out instead of keeping it alive for the lifetime of the navigation API method tracker*[p934].

17. Set *event*'s abort controller[p941] to a new `AbortController` created in *navigation*'s relevant realm[p1039].

18. Initialize *event*'s `signal`[p941] to *event*'s abort controller[p941]'s signal.

19. Let *currentURL* be *document*'s URL.

20. If all of the following are true:

    - *destination*'s is same document[p943] is true;
    - *destination*'s URL[p942] equals *currentURL* with *exclude fragments* set to true; and
    - *destination*'s URL[p942]'s fragment is not identical to *currentURL*'s fragment

    then initialize *event*'s `hashChange`[p941] to true. Otherwise, initialize it to false.

21. If *userInvolvement* is not "`none`[p977]", then initialize *event*'s `userInitiated`[p941] to true. Otherwise, initialize it to false.

22. If *formDataEntryList* is not null, then initialize *event*'s `formData`[p941] to a new `FormData` created in *navigation*'s relevant realm[p1039], associated to *formDataEntryList*. Otherwise, initialize it to null.

23. Assert: *navigation*'s ongoing `navigate` event[p934] is null.

24. Set *navigation*'s ongoing `navigate` event[p934] to *event*.

25. Set *navigation*'s focus changed during ongoing navigation[p934] to false.

26. Set *navigation*'s suppress normal scroll restoration during ongoing navigation[p934] to false.

27. Let *dispatchResult* be the result of dispatching *event* at *navigation*.

28. If *dispatchResult* is false:

    1. If *navigationType* is "traverse[p924]", then consume history-action user activation[p812].

    2. If *event*'s abort controller[p941]'s signal is not aborted, then abort the ongoing navigation[p937] given *navigation*.

    3. Return false.

29. Let *endResultIsSameDocument* be true if *event*'s interception state[p941] is not "none" or *event*'s destination[p941]'s is same document[p943] is true.

30. Prepare to run script[p1052] given *navigation*'s relevant settings object[p1039].

    Note

    This is done to avoid the JavaScript execution context stack becoming empty right after any currententrychange[p1406] event handlers run as a result of the URL and history update steps[p991] that could soon happen. If the stack were to become empty at that time, then it would immediately perform a microtask checkpoint[p1077], causing various promise fulfillment handlers to run interleaved with the event handlers and before any handlers passed to navigateEvent.intercept()[p941]. This is undesirable since it means promise handler ordering vs. currententrychange[p1406] event handler ordering vs. intercept()[p941] handler ordering would be dependent on whether the navigation is happening with an empty JavaScript execution context stack (e.g., because the navigation was user-initiated) or with a nonempty one (e.g., because the navigation was caused by a JavaScript API call).

    By inserting an otherwise-unnecessary JavaScript execution context onto the stack in this step, we essentially suppress the perform a microtask checkpoint[p1077] algorithm until later, thus ensuring that the sequence is always: currententrychange[p1406] event handlers, then intercept()[p941] handlers, then promise handlers.

31. If *event*'s interception state[p941] is not "none":

    1. Set *event*'s interception state[p941] to "committed".

    2. Let *fromNHE* be the current entry[p923] of *navigation*.

    3. Assert: *fromNHE* is not null.

    4. Set *navigation*'s transition[p938] to a new NavigationTransition[p938] created in *navigation*'s relevant realm[p1039], whose navigation type[p938] is *navigationType*, from entry[p938] is *fromNHE*, and whose finished promise[p938] is a new promise created in *navigation*'s relevant realm[p1039].

    5. Mark as handled *navigation*'s transition[p938]'s finished promise[p938].

       Note

       See the discussion about other finished promises[p935] to understand why this is done.

    6. If *navigationType* is "traverse[p924]", then set *navigation*'s suppress normal scroll restoration during ongoing navigation[p934] to true.

       Note

       If event's *scroll behavior[p941] was set to "after-transition[p939]", then scroll restoration will happen as part of finishing[p948] the relevant NavigateEvent[p939]. Otherwise, there will be no scroll restoration. That is, no navigation which is intercepted by intercept()[p941] goes through the normal scroll restoration process; scroll restoration for such navigations is either done manually, by the web developer, or is done after the transition.*

    7. If *navigationType* is "push[p923]" or "replace[p923]", then run the URL and history update steps[p991] given *document* and *event*'s destination[p941]'s URL[p943], with *serialiedData[p991]* set to *event*'s classic history API state[p941] and *historyHandling[p991]* set to *navigationType*.

       Note

       If navigationType *is "reload[p924]", then we are converting a reload[p990] into a "same-document reload", for which the URL and history update steps[p991] are not appropriate. Navigation API-related stuff still happens, such as updating the active session history entry[p952]'s navigation API state[p968] if this was caused by a call to navigation.reload()[p931], and all the ongoing navigation tracking[p933].*

       If navigationType *is "traverse[p924]", then this event firing is happening as part of the traversal process[p1002], and that process will take care of performing the appropriate session history entry updates.*

32. If *endResultIsSameDocument* is true:

    1. Let *promisesList* be an empty list.

    2. For each *handler* of *event*'s navigation handler list[p941]:

        1. Append the result of invoking *handler* with an empty arguments list to *promisesList*.

    3. If *promisesList*'s size is 0, then set *promisesList* to « a promise resolved with undefined ».

    Note

    There is a subtle timing difference between how waiting for all schedules its success and failure steps when given zero promises versus ≥1 promises. For most uses of waiting for all, this does not matter. However, with this API, there are so many events and promise handlers which could fire around the same time that the difference is pretty easily observable: it can cause the event/promise handler sequence to vary. (Some of the events and promises involved include: `navigatesuccess`[p1407] / `navigateerror`[p1407], `currententrychange`[p1406], `dispose`[p1406], apiMethodTracker'*s promises, and the* `navigation.transition.finished`[p939] *promise.)*

    4. Wait for all of *promisesList*, with the following success steps:

        1. If *event*'s relevant global object[p1039] is not fully active[p966], then abort these steps.

        2. If *event*'s abort controller[p941]'s signal is aborted, then abort these steps.

        3. Assert: *event* equals *navigation*'s ongoing `navigate` event[p934].

        4. Set *navigation*'s ongoing `navigate` event[p934] to null.

        5. Finish[p948] *event* given true.

        6. Fire an event named `navigatesuccess`[p1407] at *navigation*.

        7. If *navigation*'s transition[p938] is not null, then resolve *navigation*'s transition[p938]'s finished promise[p938] with undefined.

        8. Set *navigation*'s transition[p938] to null.

        9. If *apiMethodTracker* is non-null, then resolve the finished promise[p937] for *apiMethodTracker*.

    and the following failure steps given reason *rejectionReason*:

        1. If *event*'s relevant global object[p1039] is not fully active[p966], then abort these steps.

        2. If *event*'s abort controller[p941]'s signal is aborted, then abort these steps.

        3. Assert: *event* equals *navigation*'s ongoing `navigate` event[p934].

        4. Set *navigation*'s ongoing `navigate` event[p934] to null.

        5. Finish[p948] *event* given false.

        6. Fire an event named `navigateerror`[p1407] at *navigation* using `ErrorEvent`[p1054], with `error`[p1054] initialized to *rejectionReason*, and `message`[p1054], `filename`[p1054], `lineno`[p1054], and `colno`[p1054] initialized to appropriate values that can be extracted from *rejectionReason* in the same underspecified way that the report the exception[p1053] algorithm does.

        7. If *navigation*'s transition[p938] is not null, then reject *navigation*'s transition[p938]'s finished promise[p938] with *rejectionReason*.

        8. Set *navigation*'s transition[p938] to null.

        9. If *apiMethodTracker* is non-null, then reject the finished promise[p937] for *apiMethodTracker* with *rejectionReason*.

33. Otherwise, if *apiMethodTracker* is non-null, then clean up[p936] *apiMethodTracker*.

34. Clean up after running script[p1052] given *navigation*'s relevant settings object[p1039].

Note

Per the previous note[p946], this stops suppressing any potential promise handler microtasks, causing them to run at this point or later.

35. If *event*'s interception state[p941] is "`none`", then return true.
36. Return false.

7.2.6.9.4 Scroll and focus behavior §[p948]

By calling `navigateEvent.intercept()`[p941], web developers can suppress the normal scroll and focus behavior for same-document navigations, instead invoking cross-document navigation-like behavior at a later time. The algorithms in this section are called at those appropriate later points.

To **finish** a `NavigateEvent`[p939] *event*, given a boolean *didFulfill*:

1. Assert: *event*'s interception state[p941] is not "`intercepted`" or "`finished`".
2. If *event*'s interception state[p941] is "`none`", then return.
3. Potentially reset the focus[p948] given *event*.
4. If *didFulfill* is true, then potentially process scroll behavior[p948] given *event*.
5. Set *event*'s interception state[p941] to "`finished`".

To **potentially reset the focus** given a `NavigateEvent`[p939] *event*:

1. Assert: *event*'s interception state[p941] is "`committed`" or "`scrolled`".
2. Let *navigation* be *event*'s relevant global object[p1039]'s navigation API[p922].
3. Let *focusChanged* be *navigation*'s focus changed during ongoing navigation[p934].
4. Set *navigation*'s focus changed during ongoing navigation[p934] to false.
5. If *focusChanged* is true, then return.
6. If *event*'s focus reset behavior[p941] is "`manual`[p939]", then return.

   Note

   If it was left as null, then we treat that as "`after-transition`[p939]", and continue onward.

7. Let *document* be *event*'s relevant global object[p1039]'s associated `Document`[p894].
8. Let *focusTarget* be the autofocus delegate[p822] for *document*.
9. If *focusTarget* is null, then set *focusTarget* to *document*'s body element[p133].
10. If *focusTarget* is null, then set *focusTarget* to *document*'s document element.
11. Run the focusing steps[p822] for *focusTarget*, with *document*'s viewport as the *fallback target*.
12. Move the sequential focus navigation starting point[p825] to *focusTarget*.

To **potentially process scroll behavior** given a `NavigateEvent`[p939] *event*:

1. Assert: *event*'s interception state[p941] is "`committed`" or "`scrolled`".
2. If *event*'s interception state[p941] is "`scrolled`", then return.
3. If *event*'s scroll behavior[p941] is "`manual`[p939]", then return.

   Note

   If it was left as null, then we treat that as "`after-transition`[p939]", and continue onward.

4. Process scroll behavior[p949] given *event*.

To **process scroll behavior** given a NavigateEvent[p939] *event*:

1. Assert: *event*'s interception state[p941] is "committed".
2. Set *event*'s interception state[p941] to "scrolled".
3. If *event*'s navigationType[p941] was initialized to "traverse[p924]" or "reload[p924]", then restore scroll position data[p1013] given *event*'s relevant global object[p1039]'s navigable[p894]'s active session history entry[p952].
4. Otherwise:
    1. Let *document* be *event*'s relevant global object[p1039]'s associated Document[p894].
    2. If *document*'s indicated part[p1012] is null, then scroll to the beginning of the document given *document*. [CSSOMVIEW][p1412]
    3. Otherwise, scroll to the fragment[p1011] given *document*.

7.2.7 Event interfaces §[p949]

Note

The NavigateEvent[p939] interface has its own dedicated section[p939], due to its complexity.

7.2.7.1 The NavigationCurrentEntryChangeEvent[p949] interface §[p949]

IDL

```
[Exposed=Window]
interface NavigationCurrentEntryChangeEvent : Event {
  constructor(DOMString type, NavigationCurrentEntryChangeEventInit eventInitDict);

  readonly attribute NavigationType? navigationType;
  readonly attribute NavigationHistoryEntry from;
};

dictionary NavigationCurrentEntryChangeEventInit : EventInit {
  NavigationType? navigationType = null;
  required NavigationHistoryEntry from;
};
```

For web developers (non-normative)

***event*.navigationType[p949]**

Returns the type of navigation which caused the current entry to change, or null if the change is due to navigation.updateCurrentEntry()[p928].

***event*.from[p949]**

Returns the previous value of navigation.currentEntry[p928], before the current entry changed.

If navigationType[p949] is null or "reload[p924]", then this value will be the same as navigation.currentEntry[p928]. In that case, the event signifies that the contents of the entry changed, even if we did not move to a new entry or replace the current one.

The **navigationType** and **from** attributes must return the values they were initialized to.

7.2.7.2 The PopStateEvent[p949] interface §[p949]

IDL

```
[Exposed=Window]
interface PopStateEvent : Event {
```

```
  constructor(DOMString type, optional PopStateEventInit eventInitDict = {});

  readonly attribute any state;
};

dictionary PopStateEventInit : EventInit {
  any state = null;
};
```

For web developers (non-normative)

***event*.state**[p950]

Returns a copy of the information that was provided to pushState()[p917] or replaceState()[p917].

The **state** attribute must return the value it was initialized to. It represents the context information for the event, or null, if the state represented is the initial state of the Document[p127].

7.2.7.3 The HashChangeEvent[p950] interface §[p950]

IDL

```
[Exposed=Window]
interface HashChangeEvent : Event {
  constructor(DOMString type, optional HashChangeEventInit eventInitDict = {});

  readonly attribute USVString oldURL;
  readonly attribute USVString newURL;
};

dictionary HashChangeEventInit : EventInit {
  USVString oldURL = "";
  USVString newURL = "";
};
```

For web developers (non-normative)

***event*.oldURL**[p950]

Returns the URL of the session history entry[p968] that was previously current.

***event*.newURL**[p950]

Returns the URL of the session history entry[p968] that is now current.

The **oldURL** attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the session history entry[p968] that was traversed from.

The **newURL** attribute must return the value it was initialized to. It represents context information for the event, specifically the URL of the session history entry[p968] that was traversed to.

7.2.7.4 The PageTransitionEvent[p950] interface §[p950]

IDL

```
[Exposed=Window]
interface PageTransitionEvent : Event {
  constructor(DOMString type, optional PageTransitionEventInit eventInitDict = {});

  readonly attribute boolean persisted;
};

dictionary PageTransitionEventInit : EventInit {
  boolean persisted = false;
```

```
};
```

For web developers (non-normative)

***event*.persisted**[p951]

For the pageshow[p1407] event, returns false if the page is newly being loaded (and the load[p1407] event will fire). Otherwise, returns true.

For the pagehide[p1407] event, returns false if the page is going away for the last time. Otherwise, returns true, meaning that the page might be reused if the user navigates back to this page (if the Document[p127]'s *salvageable*[p1021] state stays true).

Things that can cause the page to be unsalvageable include:

- The user agent decided to not keep the Document[p127] alive in a session history entry[p968] after unload[p1021]
- Having iframe[p383]s that are not *salvageable*[p1021]
- Active WebSocket objects
- Aborting a Document[p1023]

The **persisted** attribute must return the value it was initialized to. It represents the context information for the event.

To **fire a page transition event** named *eventName* at a Window[p892] *window* with a boolean *persisted*, fire an event named *eventName* at *window*, using PageTransitionEvent[p950], with the persisted[p951] attribute initialized to *persisted*, the cancelable attribute initialized to true, the bubbles attribute initialized to true, and *legacy target override flag* set.

Note

The values for cancelable and bubbles don't make any sense, since canceling the event does nothing and it's not possible to bubble past the Window[p892] object. They are set to true for historical reasons.

MDN

7.2.7.5 The BeforeUnloadEvent[p951] interface §[p951]

IDL

```
[Exposed=Window]
interface BeforeUnloadEvent : Event {
  attribute DOMString returnValue;
};
```

Note

There are no BeforeUnloadEvent[p951]-specific initialization methods.

The BeforeUnloadEvent[p951] interface is a legacy interface which allows checking if unloading is canceled[p987] to be controlled not only by canceling the event, but by setting the returnValue[p951] attribute to a value besides the empty string. Authors should use the preventDefault() method, or other means of canceling events, instead of using returnValue[p951].

The **returnValue** attribute controls the process of checking if unloading is canceled[p987]. When the event is created, the attribute must be set to the empty string. On getting, it must return the last value it was set to. On setting, the attribute must be set to the new value.

Note

This attribute is a DOMString only for historical reasons. Any value besides the empty string will be treated as a request to ask the user for confirmation.

7.3 Infrastructure for sequences of documents §[p951]

This standard contains several related concepts for grouping sequences of documents. As a brief, non-normative summary:

- Navigables[p952] are a user-facing representation of a sequence of documents, i.e., they represent something that can be navigated between documents. Typical examples are tabs or windows in a web browser, or iframe[p383]s, or frame[p1369]s in a

frameset[p1369].

- Traversable navigables[p953] are a special type of navigable which control the session history of themselves and of their descendant navigables. That is, in addition to their own series of documents, they represent a tree of further series of documents, plus the ability to linearly traverse back and forward through a flattened view of this tree.
- Browsing contexts[p961] are a developer-facing representation of a series of documents. They correspond 1:1 with WindowProxy[p904] objects. Each navigable can present a series of browsing contexts, with switches[p876] between those browsing contexts occuring under certain well-defined circumstances.

Most of this standard works in the language of navigables, but certain APIs expose the existence of browsing context switches, and so some parts of the standard need to work in terms of browsing contexts.

7.3.1 Navigables §[p952]

A **navigable** presents a Document[p127] to the user via its active session history entry[p952]. Each navigable has:

- An **id**, a new unique internal value[p94].
- A **parent**, a navigable[p952] or null.
- A **current session history entry**, a session history entry[p968].

  This can only be modified within the session history traversal queue[p953] of the parent traversable navigable[p953].
- An **active session history entry**, a session history entry[p968].

  This can only be modified from the event loop of the active session history entry[p952]'s document[p968].
- An **is closing** boolean, initially false.

  Note

  This is only ever set to true for top-level traversable navigables[p953].
- An **is delaying load events** boolean, initially false.

  Note

  This is only ever set to true in cases where the navigable's parent[p952] is non-null.

The current session history entry[p952] and the active session history entry[p952] are usually the same, but they get out of sync when:

- Synchronous navigations are performed. This causes the active session history entry[p952] to temporarily step ahead of the current session history entry[p952].
- A non-displayable, non-error response is received when applying the history step[p1002]. This updates the current session history entry[p952] but leaves the active session history entry[p952] as-is.

A navigable[p952]'s **active document** is its active session history entry[p952]'s document[p968].

Note

This can be safely read from within the session history traversal queue[p953] of the navigable's top-level traversable[p954]. Although a navigable[p952]'s active history entry[p952] can change synchronously, the new entry will always have the same Document[p127].

A navigable[p952]'s **active browsing context** is its active document[p952]'s browsing context[p961]. If this navigable[p952] is a traversable navigable[p953], then its active browsing context[p952] will be a top-level browsing context[p964].

A navigable[p952]'s **active WindowProxy** is its active browsing context[p952]'s associated WindowProxy[p904].

A navigable[p952]'s **active window** is its active WindowProxy[p952]'s [[Window]][p904].

Note

This will always equal the navigable's active document[p952]'s relevant global object[p1039]; this is kept in sync by the make active[p1010] algorithm.

A navigable[p952]'s **target name** is its active session history entry[p952]'s document state[p968]'s navigable target name[p970].

To get the **node navigable** of a node *node*, return the navigable[p952] whose active document[p952] is *node*'s node document, or null if there is no such navigable[p952].

To **initialize the navigable** navigable[p952] *navigable*, given a document state[p969] *documentState* and an optional navigable[p952]-or-null *parent* (default null):

1. Assert: *documentState*'s document[p969] is non-null.
2. Let *entry* be a new session history entry[p968], with

   URL[p968]
   documentState's document[p969]'s URL
   document state[p968]
   documentState

   Note

   The caller of this algorithm is responsible for initializing entry's *step[p968]; it will be left as* "`pending`" *until that is complete.*

3. Set *navigable*'s current session history entry[p952] to *entry*.
4. Set *navigable*'s active session history entry[p952] to *entry*.
5. Set *navigable*'s parent[p952] to *parent*.

7.3.1.1 Traversable navigables §[p953]

A **traversable navigable** is a navigable[p952] that also controls which session history entry[p968] should be the current session history entry[p952] and active session history entry[p952] for itself and its descendant navigables[p952].

In addition to the properties of a navigable[p952], a traversable navigable[p953] has:

- A **current session history step**, a number, initially 0.
- **Session history entries**, a list of session history entries[p968], initially a new list.
- A **session history traversal queue**, a session history traversal parallel queue[p970], the result of starting a new session history traversal parallel queue[p971].
- A **running nested apply history step** boolean, initially false.
- A **system visibility state**, which is either "`hidden`" or "`visible`".

  See the page visibility[p807] section for the requirements on this item.

To get the **traversable navigable** of a navigable[p952] *inputNavigable*:

1. Let *navigable* be *inputNavigable*.
2. While *navigable* is not a traversable navigable[p953], set *navigable* to *navigable*'s parent[p952].
3. Return *navigable*.

7.3.1.2 Top-level traversables §[p953]

A **top-level traversable** is a traversable navigable[p953] with a null parent[p952].

Note

Currently, all traversable navigables[p953] are top-level traversables[p953]. Future proposals envision introducing non-top-level traversables.

A user agent holds a **top-level traversable set** (a set of top-level traversables[p953]). These are typically presented to the user in the form of browser windows or browser tabs.

To get the **top-level traversable** of a navigable[p952] *inputNavigable*:

1. Let *navigable* be *inputNavigable*.
2. While *navigable*'s parent[p952] is not null, set *navigable* to *navigable*'s parent[p952].
3. Return *navigable*.

To **create a new top-level traversable** given a browsing context[p961]-or-null *opener* and a string *targetName*:

1. Let *document* be null.
2. If *opener* is null, then set *document* to the second return value of creating a new top-level browsing context and document[p963].
3. Otherwise, set *document* to the second return value of creating a new auxiliary browsing context and document[p963] given *opener*.
4. Let *documentState* be a new document state[p969], with

   document[p969]
   document
   initiator origin[p969]
   null if *opener* is null; otherwise, *document*'s origin
   origin[p969]
   document's origin
   navigable target name[p970]
   targetName
   about base URL[p969]
   document's about base URL[p128]

5. Let *traversable* be a new traversable navigable[p953].
6. Initialize the navigable[p953] *traversable* given *documentState*.
7. Let *initialHistoryEntry* be *traversable*'s active session history entry[p952].
8. Set *initialHistoryEntry*'s step[p968] to 0.
9. Append *initialHistoryEntry* to *traversable*'s session history entries[p953].
10. If *opener* is non-null, then legacy-clone a traversable storage shed given *opener*'s top-level traversable[p961] and *traversable*. [STORAGE][p1417]
11. Append *traversable* to the user agent's top-level traversable set[p954].
12. Return *traversable*.

To **create a fresh top-level traversable** given a URL *initialNavigationURL* and an optional POST resource[p970]-or-null *initialNavigationPostResource* (default null):

1. Let *traversable* be the result of creating a new top-level traversable[p954] given null and the empty string.
2. Navigate[p977] *traversable* to *initialNavigationURL* using *traversable*'s active document[p952], with *documentResource*[p977] set to *initialNavigationPostResource*.

   Note

   We treat these initial navigations as traversable *navigating itself, which will ensure all relevant security checks pass.*

3. Return *traversable*.

7.3.1.3 Child navigables §[p955]

Certain elements (for example, `iframe`[p383] elements) can present a navigable[p952] to the user. These elements are called **navigable containers**.

Each navigable container[p955] has a **content navigable**, which is either a navigable[p952] or null. It is initially null.

The **container** of a navigable[p952] *navigable* is the navigable container[p955] whose content navigable[p955] is *navigable*, or null if there is no such element.

The **container document** of a navigable[p952] *navigable* is the result of running these steps:

1. If *navigable*'s container[p955] is null, then return null.
2. Return *navigable*'s container[p955]'s node document.

> **Note**
> *This is equal to* navigable's *container[p955]'s shadow-including root as* navigable's *container[p955] has to be connected.*

The **container document** of a `Document`[p127] *document* is the result of running these steps:

1. If *document*'s node navigable[p953] is null, then return null.
2. Return *document*'s node navigable[p953]'s container document[p955].

A navigable[p952] *navigable* is a **child navigable** of another navigable *potentialParent* when *navigable*'s parent[p952] is *potentialParent*. We can also just say that a navigable[p952] "is a child navigable[p955]", which means that its parent[p952] is non-null.

> **Note**
> *All child navigables[p955] are the content navigable[p955] of their container[p955].*

The **content document** of a navigable container[p955] *container* is the result of running these steps:

1. If *container*'s content navigable[p955] is null, then return null.
2. Let *document* be *container*'s content navigable[p955]'s active document[p952].
3. If *document*'s origin and *container*'s node document's origin are not same origin-domain[p870], then return null.
4. Return *document*.

The **content window** of a navigable container[p955] *container* is the result of running these steps:

1. If *container*'s content navigable[p955] is null, then return null.
2. Return *container*'s content navigable[p955]'s active `WindowProxy`[p952]'s object.

To **create a new child navigable**, given an element *element*:

1. Let *parentNavigable* be *element*'s node navigable[p953].
2. Let *group* be *element*'s node document's browsing context[p961]'s top-level browsing context[p964]'s group[p965].
3. Let *browsingContext* and *document* be the result of creating a new browsing context and document[p962] given *element*'s node document, *element*, and *group*.
4. Let *targetName* be null.
5. If *element* has a `name` content attribute, then set *targetName* to the value of that attribute.
6. Let *documentState* be a new document state[p969], with

   document[p969]
   document
   initiator origin[p969]
   document's origin

origin [p969]
document's origin
navigable target name [p970]
targetName
about base URL [p969]
document's about base URL [p128]

7. Let *navigable* be a new navigable [p952].

8. Initialize the navigable [p953] *navigable* given *documentState* and *parentNavigable*.

9. Set *element*'s content navigable [p955] to *navigable*.

10. Let *historyEntry* be *navigable*'s active session history entry [p952].

11. Let *traversable* be *parentNavigable*'s traversable navigable [p953].

12. Append the following session history traversal steps [p971] to *traversable*:

    1. Let *parentDocState* be *parentNavigable*'s active session history entry [p952]'s document state [p968].

    2. Let *targetStepSHE* be the first session history entry [p968] in *traversable*'s session history entries [p953] whose document state [p968] equals *parentDocState*.

    3. Set *historyEntry*'s step [p968] to *targetStepSHE*'s step [p968].

    4. Let *nestedHistory* be a new nested history [p970] whose id [p970] is *navigable*'s id [p952] and entries list [p970] is « *historyEntry* ».

    5. Append *nestedHistory* to *parentDocState*'s nested histories [p969].

    6. Update for navigable creation/destruction [p1002] given *traversable*.

7.3.1.4 Jake diagrams §[p956]

A useful method for visualizing sequences of documents, and in particular navigables [p952] and their session history entries [p968], is the **Jake diagram**. A typical Jake diagram is the following:

	0	1	2	3	4
top	***/t-a***			/t-a#foo	/t-b
frames[0]	/i-0-a	***/i-0-b***			
frames[1]	***/i-1-a***	/i-1-b			

Here, each numbered column denotes a possible value for the traversable's session history step [p953]. Each labeled row depicts a navigable [p952], as it transitions between different URLs and documents. The first, labeled `top`, being the top-level traversable [p953], and the others being child navigables [p955]. The documents are given by the background color of each cell, with a new background color indicating a new document in that navigable [p952]. The URLs are given by the text content of the cells; usually they are given as relative URLs for brevity, unless a cross-origin case is specifically under investigation. A given navigable might not exist at a given step, in which case the corresponding cells are empty. The bold-italic step number depicts the current session history step [p953] of the traversable, and all cells with bold-italic URLs represent the current session history entry [p952] for that row's navigable.

Thus, the above Jake diagram depicts the following sequence of events:

0. A top-level traversable [p953] is created, starting a the URL `/t-a`, with two child navigables [p955] starting at `/i-0-a` and `/i-1-a` respectively.

1. The first child navigable is navigated [p977] to another document, with URL `/i-0-b`.

2. The second child navigable is navigated [p977] to another document, with URL `/i-1-b`.

3. The top-level traversable is navigated [p977] to the *same* document, updating its URL to `/t-a#foo`.

4. The top-level traversable is navigated [p977] to another document, with URL `/t-b`. (Notice how this document, of course, does not carry over the old document's child navigables.)

5. The traversable was traversed by a delta [p990] of −3, back to step 1.

Jake diagrams[p956] are a powerful tool for visualizing the interactions of multiple navigables, navigations, and traversals. They cannot capture every possible interaction — for example, they only work with a single level of nesting — but we will have ocassion to use them to illustrate several complex situations throughout this standard.

Note

Jake diagrams[p956] are named after their creator, the inimitable Jake Archibald.

7.3.1.5 Related navigable collections §[p957]

It is often helpful in this standard's algorithms to look at collections of navigables[p952] starting at a given `Document`[p127]. This section contains a curated set of algorithms for collecting those navigables.

Note

The return values of these algorithms are ordered so that parents appears before their children. Callers rely on this ordering.

Note

Starting with a `Document`[p127], rather than a navigable[p952], is generally better because it makes the caller cognizant of whether they are starting with a fully active[p966] `Document`[p127] or not. Although non-fully active[p966] `Document`[p127]s do have ancestor and descendant navigables, they often behave as if they don't (e.g., in the `window.parent`[p901] getter).

The **ancestor navigables** of a `Document`[p127] *document* are given by these steps:

1. Let *navigable* be *document*'s node navigable[p953]'s parent[p952].
2. Let *ancestors* be an empty list.
3. While *navigable* is not null:
    1. Prepend *navigable* to *ancestors*.
    2. Set *navigable* to *navigable*'s parent[p952].
4. Return *ancestors*.

The **inclusive ancestor navigables** of a `Document`[p127] *document* are given by these steps:

1. Let *navigables* be *document*'s ancestor navigables[p957].
2. Append *document*'s node navigable[p953] to *navigables*.
3. Return *navigables*.

The **descendant navigables** of a `Document`[p127] *document* are given by these steps:

1. Let *navigables* be new list.
2. Let *navigableContainers* be a list of all shadow-including descendants of *document* that are navigable containers[p955], in shadow-including tree order.
3. For each *navigableContainer* of *navigableContainers*:
    1. If *navigableContainer*'s content navigable[p955] is null, then continue.
    2. Extend *navigables* with *navigableContainer*'s content navigable[p955]'s active document[p952]'s inclusive descendant navigables[p957].
4. Return *navigables*.

The **inclusive descendant navigables** of a `Document`[p127] *document* are given by these steps:

1. Let *navigables* be « *document*'s node navigable[p953] ».
2. Extend *navigables* with *document*'s descendant navigables[p957].

3. Return *navigables*.

Note

These descendant-collecting algorithms are described as looking at the DOM tree of descendant `Document`[p127] *objects. In reality, this is often not feasible since the DOM tree can be in another process from the caller of the algorithm. Instead, implementations generally replicate the appropriate trees across processes.*

The **document-tree child navigables** of a `Document`[p127] *document* are given by these steps:

1. If *document*'s node navigable[p953] is null, then return the empty list.
2. Let *navigables* be new list.
3. Let *navigableContainers* be a list of all descendants of *document* that are navigable containers[p955], in tree order.
4. For each *navigableContainer* of *navigableContainers*:
    1. If *navigableContainer*'s content navigable[p955] is null, then continue.
    2. Append *navigableContainer*'s content navigable[p955] to *navigables*.
5. Return *navigables*.

7.3.1.6 Navigable destruction §[p958]

To **destroy a child navigable** given a navigable container[p955] *container*:

1. Let *navigable* be *container*'s content navigable[p955].
2. If *navigable* is null, then return.
3. Set *container*'s content navigable[p955] to null.
4. Inform the navigation API about child navigable destruction[p938] given *navigable*.
5. Destroy[p1023] *navigable*'s active document[p952].
6. Let *parentDocState* be *container*'s node navigable[p953]'s active session history entry[p952]'s document state[p968].
7. Remove the nested history[p970] from *parentDocState*'s nested histories[p969] whose id[p970] equals *navigable*'s id[p952].
8. Let *traversable* be *container*'s node navigable[p953]'s traversable navigable[p953].
9. Append the following session history traversal steps[p971] to *traversable*:
    1. Update for navigable creation/destruction[p1002] given *traversable*.

To **destroy a top-level traversable** given a top-level traversable[p953] *traversable*:

1. Let *browsingContext* be *traversable*'s active browsing context[p952].
2. For each *historyEntry* in *traversable*'s session history entries[p953] in what order?:
    1. Let *document* be *historyEntry*'s document[p968].
    2. If *document* is not null, then destroy[p1023] *document*.
3. Remove[p966] *browsingContext*.
4. Remove *traversable* from the user interface (e.g., close or hide its tab in a tabbed browser).
5. Remove *traversable* from the user agent's top-level traversable set[p954].

User agents may destroy a top-level traversable[p958] at any time (typically, in response to user requests[p1026]).

To **close a top-level traversable** *traversable*:

1. If *traversable*'s is closing[p952] is true, then return.
2. Let *toUnload* be *traversable*'s active document[p952]'s inclusive descendant navigables[p957].
3. If the result of checking if unloading is canceled[p987] for *toUnload* is true, then return.
4. Unload[p1021] the active documents[p952] of each of *toUnload*. In what order?
5. Destroy[p958] *traversable*.

7.3.1.7 Navigable target names §[p959]

Navigables[p952] can be given target names[p953], which are strings allowing certain APIs (such as `window.open()`[p896] or the `a`[p252] element's `target`[p297] attribute) to target navigations[p977] at that navigable.

A **valid navigable target name** is any string with at least one character that does not start with a U+005F LOW LINE character. (Names starting with an underscore are reserved for special keywords.)

A **valid navigable target name or keyword** is any string that is either a valid navigable target name[p959] or that is an ASCII case-insensitive match for one of: `_blank`, `_self`, `_parent`, or `_top`.

These values have different meanings based on whether the page is sandboxed or not, as summarized in the following (non-normative) table. In this table, "current" means the navigable[p952] that the link or script is in, "parent" means the parent[p952] of the navigable[p952] that the link or script is in, "top" means the top-level traversable[p954] of the navigable[p952] that the link or script is in, "new" means a new traversable navigable[p953] with a null parent[p952] (which may use an auxiliary browsing context[p961], subject to various user preferences and user agent policies), "none" means that nothing will happen, and "maybe new" means the same as "new" if the "`allow-popups`[p886]" keyword is also specified on the `sandbox`[p388] attribute (or if the user overrode the sandboxing), and the same as "none" otherwise.

Keyword	Ordinary effect	Effect in an `iframe`[p383] with...	
		`sandbox=""`	`sandbox="allow-top-navigation"`
none specified, for links and form submissions	current	current	current
empty string	current	current	current
`_blank`	new	maybe new	maybe new
`_self`	current	current	current
`_parent` if there isn't a parent	current	current	current
`_parent` if parent is also top	parent/top	none	parent/top
`_parent` if there is one and it's not top	parent	none	none
`_top` if top is current	current	current	current
`_top` if top is not current	top	none	top
name that doesn't exist	new	maybe new	maybe new
name that exists and is a descendant	specified descendant	specified descendant	specified descendant
name that exists and is current	current	current	current
name that exists and is an ancestor that is top	specified ancestor	none	specified ancestor/top
name that exists and is an ancestor that is not top	specified ancestor	none	none
other name that exists with common top	specified	none	none
name that exists with different top, if familiar[p964] and one permitted sandboxed navigator[p885]	specified	specified	specified
name that exists with different top, if familiar[p964] but not one permitted sandboxed navigator[p885]	specified	none	none
name that exists with different top, not familiar[p964]	new	maybe new	maybe new

Most of the restrictions on sandboxed browsing contexts are applied by other algorithms, e.g. the navigation[p977] algorithm, not the rules for choosing a navigable[p959] given below.

The rules for choosing a navigable, given a string *name*, a navigable[p952] *currentNavigable*, and a boolean *noopener* are as follows:

1. Let *chosen* be null.

2. Let *windowType* be "`existing or none`".

3. Let *sandboxingFlagSet* be *currentNavigable*'s active document[p952]'s active sandboxing flag set[p887].

4. If *name* is the empty string or an ASCII case-insensitive match for "`_self`", then set *chosen* to *currentNavigable*.

5. Otherwise, if *name* is an ASCII case-insensitive match for "`_parent`", set *chosen* to *currentNavigable*'s parent[p952], if any, and *currentNavigable* otherwise.

6. Otherwise, if *name* is an ASCII case-insensitive match for "`_top`", set *chosen* to *currentNavigable*'s traversable navigable[p953].

7. Otherwise, if *name* is not an ASCII case-insensitive match for "`_blank`", there exists a navigable[p952] whose target name[p953] is the same as *name*, *currentNavigable*'s active browsing context[p952] is familiar with[p964] that navigable[p952]'s active browsing context[p952], and the user agent determines that the two browsing contexts are related enough that it is ok if they reach each other, set *chosen* to that navigable. If there are multiple matching navigables[p952], the user agent should pick one in some arbitrary consistent manner, such as the most recently opened, most recently focused, or more closely related, and set *chosen* to it.

   This will be made more precise in issue #313.

8. Otherwise, a new top-level traversable[p953] is being requested, and what happens depends on the user agent's configuration and abilities — it is determined by the rules given for the first applicable option from the following list:

   ↪ **If *currentNavigable*'s active window[p952] does not have transient activation[p811] and the user agent has been configured to not show popups (i.e., the user agent has a "popup blocker" enabled)**

   The user agent may inform the user that a popup has been blocked.

   ↪ **If *sandboxingFlagSet* has the sandboxed auxiliary navigation browsing context flag[p885] set**

   The user agent may report to a developer console that a popup has been blocked.

   ↪ **If the user agent has been configured such that in this instance it will create a new top-level traversable[p953]**

   1. Set *windowType* to "`new and unrestricted`".

   2. Let *currentDocument* be *currentNavigable*'s active document[p952].

   3. If *currentDocument*'s cross-origin opener policy[p128]'s value[p874] is "`same-origin`[p874]" or "`same-origin-plus-COEP`[p874]", and *currentDocument*'s origin is not same origin[p870] with *currentDocument*'s relevant settings object[p1039]'s top-level origin[p1031], then:

      1. Set *noopener* to true.

      2. Set *name* to "`_blank`".

      3. Set *windowType* to "`new with no opener`".

      Note

      In the presence of a cross-origin opener policy[p874], nested documents that are cross-origin with their top-level browsing context's active document always set noopener *to true.*

   4. Let *chosen* be null.

   5. Let *targetName* be the empty string.

   6. If *name* is not an ASCII case-insensitive match for "`_blank`", then set *targetName* to *name*.

   7. If *noopener* is true, then set *chosen* to the result of creating a new top-level traversable[p954] given null and *targetName*.

   8. Otherwise:

      1. Set *chosen* to the result of creating a new top-level traversable[p954] given *currentNavigable*'s active browsing context[p952] and *targetName*.

      2. If *sandboxingFlagSet*'s sandboxed navigation browsing context flag[p885] is set, then set *chosen*'s active browsing context[p952]'s one permitted sandboxed navigator[p885] to *currentNavigable*'s active browsing context[p952].

9. If *sandboxingFlagSet*'s sandbox propagates to auxiliary browsing contexts flag[p885] is set, then all the flags that are set in *sandboxingFlagSet* must be set in *chosen*'s active browsing context[p952]'s popup sandboxing flag set[p887].

> **Note**
> *If the newly created navigable[p952] chosen is immediately navigated[p977], then the navigation will be done as a "`replace`[p976]" navigation.*

↪ **If the user agent has been configured such that in this instance it will choose *currentNavigable***

Set *chosen* to *currentNavigable*.

↪ **If the user agent has been configured such that in this instance it will not find a navigable**

Do nothing.

> **Note**
> *User agents are encouraged to provide a way for users to configure the user agent to always choose* currentNavigable.

9. Return *chosen* and *windowType*.

7.3.2 Browsing contexts §[p961]

A **browsing context** is a programmatic representation of a series of documents, multiple of which can live within a single navigable[p952]. Each browsing context[p961] has a corresponding `WindowProxy`[p904] object, as well as the following:

- An **opener browsing context**, a browsing context[p961] or null, initially null.
- An **opener origin at creation**, an origin[p869] or null, initially null.
- An **is popup** boolean, initially false.

> **Note**
> *The only mandatory impact in this specification of is popup[p961] is on the `visible`[p902] getter of the relevant `BarProp`[p902] objects. However, user agents might also use it for user interface considerations[p1026].*

- An **is auxiliary** boolean, initially false.
- An **initial URL**, a URL or null, initially null.
- A **virtual browsing context group ID** integer, initially 0. This is used by cross-origin opener policy reporting[p874], to keep track of the browsing context group switches that would have happened if the report-only policy had been enforced.

A browsing context[p961]'s **active window** is its `WindowProxy`[p904] object's [[Window]][p904] internal slot value. A browsing context[p961]'s **active document** is its active window[p961]'s associated `Document`[p894].

A browsing context[p961]'s **top-level traversable** is its active document[p961]'s node navigable[p953]'s top-level traversable[p954].

A browsing context[p961] whose is auxiliary[p961] is true is known as an **auxiliary browsing context**. Auxiliary browsing contexts are always top-level browsing contexts[p964].

> It's unclear whether a separate is auxiliary[p961] concept is necessary. In issue #5680, it is indicated that we may be able to simplify this by using whether or not the opener browsing context[p961] is null.

> **⚠Warning!**
> ***Modern specifications should avoid using the browsing context[p961] concept in most cases, unless they are dealing with the subtleties of browsing context group switches[p876] and agent cluster allocation[p965]. Instead, the `Document`[p127] and navigable[p952] concepts are usually more appropriate.***

A **`Document`'s browsing context** is a browsing context[p961] or null, initially null.

Note

A Document[p127] does not necessarily have a non-null browsing context[p961]. In particular, data mining tools are likely to never instantiate browsing contexts. A Document[p127] created using an API such as createDocument() never has a non-null browsing context[p961]. And the Document[p127] originally created for an iframe[p383] element, which has since been removed from the document[p46], has no associated browsing context, since that browsing context was nulled out[p1023].

Note

In general, there is a 1-to-1 mapping from the Window[p892] object to the Document[p127] object, as long as the Document[p127] object has a non-null browsing context[p961]. There is one exception. A Window[p892] can be reused for the presentation of a second Document[p127] in the same browsing context[p961], such that the mapping is then 1-to-2. This occurs when a browsing context[p961] is navigated[p977] from the initial about:blank[p128] Document[p127] to another, which will be done with replacement[p976].

7.3.2.1 Creating browsing contexts §[p962]

To **create a new browsing context and document**, given null or a Document[p127] object *creator*, null or an element *embedder*, and a browsing context group[p965] *group*:

1. Let *browsingContext* be a new browsing context[p961].
2. Let *unsafeContextCreationTime* be the unsafe shared current time.
3. Let *creatorOrigin* be null.
4. Let *creatorBaseURL* be null.
5. If *creator* is non-null, then:
    1. Set *creatorOrigin* to *creator*'s origin.
    2. Set *creatorBaseURL* to *creator*'s document base URL[p94].
    3. Set *browsingContext*'s virtual browsing context group ID[p961] to *creator*'s browsing context[p961]'s top-level browsing context[p964]'s virtual browsing context group ID[p961].
6. Let *sandboxFlags* be the result of determining the creation sandboxing flags[p887] given *browsingContext* and *embedder*.
7. Let *origin* be the result of determining the origin[p964] given about:blank[p53], *sandboxFlags*, and *creatorOrigin*.
8. Let *permissionsPolicy* be the result of creating a permissions policy given *embedder* and *origin*. [PERMISSIONSPOLICY][p1415]
9. Let *agent* be the result of obtaining a similar-origin window agent[p1029] given *origin*, *group*, and false.
10. Let *realm execution context* be the result of creating a new realm[p1033] given *agent* and the following customizations:
    - For the global object, create a new Window[p892] object.
    - For the global **this** binding, use *browsingContext*'s WindowProxy[p904] object.
11. Let *topLevelCreationURL* be about:blank[p53] if *embedder* is null; otherwise *embedder*'s relevant settings object[p1039]'s top-level creation URL[p1031].
12. Let *topLevelOrigin* be *origin* if *embedder* is null; otherwise *embedder*'s relevant settings object[p1039]'s top-level origin[p1031].
13. Set up a window environment settings object[p903] with about:blank[p53], *realm execution context*, null, *topLevelCreationURL*, and *topLevelOrigin*.
14. Let *loadTimingInfo* be a new document load timing info[p131] with its navigation start time[p131] set to the result of calling coarsen time with *unsafeContextCreationTime* and the new environment settings object[p1032]'s cross-origin isolated capability[p1032].
15. Let *document* be a new Document[p127], with:

    type
    "html"
    content type
    "text/html[p1380]"

mode
"quirks"
origin
origin
browsing context[p961]
browsingContext
permissions policy[p128]
permissionsPolicy
active sandboxing flag set[p887]
sandboxFlags
load timing info[p131]
loadTimingInfo
is initial about:blank[p128]
true
about base URL[p128]
creatorBaseURL

16. If *creator* is non-null, then:

    1. Set *document*'s referrer[p127] to the serialization of *creator*'s URL.

    2. Set *document*'s policy container[p128] to a clone[p888] of *creator*'s policy container[p128].

    3. If *creator*'s origin is same origin[p870] with *creator*'s relevant settings object[p1039]'s top-level origin[p1031], then set *document*'s cross-origin opener policy[p128] to *creator*'s browsing context[p961]'s top-level browsing context[p964]'s active document[p961]'s cross-origin opener policy[p128].

17. Assert: *document*'s URL and *document*'s relevant settings object[p1039]'s creation URL[p1031] are about:blank[p53].

18. Mark *document* as ready for post-load tasks[p1297].

19. Populate with html/head/body[p1016] given *document*.

20. Make active[p1010] *document*.

21. Completely finish loading[p1021] *document*.

22. Return *browsingContext* and *document*.

To **create a new top-level browsing context and document**:

1. Let *group* and *document* be the result of creating a new browsing context group and document[p965].

2. Return *group*'s browsing context set[p965][0] and *document*.

To **create a new auxiliary browsing context and document**, given a browsing context[p961] *opener*:

1. Let *openerTopLevelBrowsingContext* be *opener*'s top-level traversable[p961]'s active browsing context[p952].

2. Let *group* be *openerTopLevelBrowsingContext*'s group[p965].

3. Assert: *group* is non-null, as navigating[p977] invokes this directly.

4. Set *browsingContext* and *document* be the result of creating a new browsing context and document[p962] with *opener*'s active document[p952], null, and *group*.

5. Set *browsingContext*'s is auxiliary[p961] to true.

6. Append[p966] *browsingContext* to *group*.

7. Set *browsingContext*'s opener browsing context[p961] to *opener*.

8. Set *browsingContext*'s virtual browsing context group ID[p961] to *openerTopLevelBrowsingContext*'s virtual browsing context group ID[p961].

9. Set *browsingContext*'s opener origin at creation[p961] to *opener*'s active document[p952]'s origin.

10. Return *browsingContext* and *document*.

To **determine the origin**, given a URL *url*, a sandboxing flag set[p885] *sandboxFlags*, and an origin[p869]-or-null *sourceOrigin*:

1. If *sandboxFlags* has its sandboxed origin browsing context flag[p885] set, then return a new opaque origin[p869].
2. If *url* is null, then return a new opaque origin[p869].
3. If *url* is `about:srcdoc`[p94], then:
    1. Assert: *sourceOrigin* is non-null.
    2. Return *sourceOrigin*.
4. If *url* matches `about:blank`[p94] and *sourceOrigin* is non-null, then return *sourceOrigin*.
5. Return *url*'s origin.

Note

The cases that return sourceOrigin *result in two* `Document`[p127]*s that end up with the same underlying origin, meaning that* `document.domain`[p872] *affects both.*

7.3.2.2 Related browsing contexts §[p964]

A browsing context[p961] *potentialDescendant* is said to be an **ancestor** of a browsing context *potentialAncestor* if the following algorithm returns true:

1. Let *potentialDescendantDocument* be *potentialDescendant*'s active document[p961].
2. If *potentialDescendantDocument* is not fully active[p966], then return false.
3. Let *ancestorBCs* be the list obtained by taking the browsing context[p961] of the active document[p952] of each member of *potentialDescendantDocument*'s ancestor navigables[p957].
4. If *ancestorBCs* contains *potentialAncestor*, then return true.
5. Return false.

A **top-level browsing context** is a browsing context[p961] whose active document[p961]'s node navigable[p953] is a traversable navigable[p953].

Note

It is not *required to be a top-level traversable*[p953].

The **top-level browsing context** of a browsing context[p961] *start* is the result of the following algorithm:

1. If *start*'s active document[p961] is not fully active[p966], then return null.
2. Let *navigable* be *start*'s active document[p961]'s node navigable[p953].
3. While *navigable*'s parent[p952] is not null, set *navigable* to *navigable*'s parent[p952].
4. Return *navigable*'s active browsing context[p952].

⚠Warning!

The terms ancestor browsing context[p964] and top-level browsing context[p964] are rarely useful, since browsing contexts[p961] in general are usually the inappropriate specification concept to use[p961]. Note in particular that when a browsing context[p961]'s active document[p961] is not fully active[p966], it never counts as an ancestor or top-level browsing context, and as such these concepts are not useful when bfcache[p969] is in play.

Instead, use concepts such as the ancestor navigables[p957] collection, the parent navigable[p952], or a navigable's top-level traversable[p953].

A browsing context[p961] *A* is **familiar with** a second browsing context[p961] *B* if the following algorithm returns true:

1. If *A*'s active document[p961]'s origin is same origin[p870] with *B*'s active document[p961]'s origin, then return true.
2. If *A*'s top-level browsing context[p964] is *B*, then return true.
3. If *B* is an auxiliary browsing context[p961] and *A* is familiar with[p964] *B*'s opener browsing context[p961], then return true.
4. If there exists an ancestor browsing context[p964] of *B* whose active document[p961] has the same[p870] origin as the active document[p961] of *A*, then return true.

   Note

   This includes the case where A *is an ancestor browsing context[p964] of* B.

5. Return false.

7.3.2.3 Groupings of browsing contexts §[p965]

A top-level browsing context[p964] has an associated **group** (null or a browsing context group[p965]). It is initially null.

A user agent holds a **browsing context group set** (a set of browsing context groups[p965]).

A **browsing context group** holds a **browsing context set** (a set of top-level browsing contexts[p964]).

Note

A top-level browsing context[p964] is added to the group[p965] when the group is created[p965]. All subsequent top-level browsing contexts[p964] added to the group[p965] will be auxiliary browsing contexts[p961].

A browsing context group[p965] has an associated **agent cluster map** (a weak map of agent cluster keys[p1029] to agent clusters). User agents are responsible for collecting agent clusters when it is deemed that nothing can access them anymore.

A browsing context group[p965] has an associated **historical agent cluster key map**, which is a map of origins[p869] to agent cluster keys[p1029]. This map is used to ensure the consistency of the origin-keyed agent clusters[p873] feature by recording what agent cluster keys were previously used for a given origin.

Note

The historical agent cluster key map[p965] only ever gains entries over the lifetime of the browsing context group.

A browsing context group[p965] has a **cross-origin isolation mode**, which is a cross-origin isolation mode[p965]. It is initially "`none`[p965]".

A **cross-origin isolation mode** is one of three possible values: "**`none`**", "**`logical`**", or "**`concrete`**".

Note

"`logical`[p965]" *and* "`concrete`[p965]" *are similar. They are both used for browsing context groups[p965] where:*

- *every top-level* `Document`[p127] *has* `` `Cross-Origin-Opener-Policy`[p875]: `same-origin`[p874] ``*, and*
- *every* `Document`[p127] *has a* `` `Cross-Origin-Embedder-Policy`[p883] `` *header whose value is compatible with cross-origin isolation[p883].*

On some platforms, it is difficult to provide the security properties required to grant safe access to the APIs gated by the cross-origin isolated capability[p1032]. As a result, only "`concrete`[p965]" *can grant access that capability.* "`logical`[p965]" *is used on platform not supporting this capability, where various restrictions imposed by cross-origin isolation will still apply, but the capability is not granted.*

To **create a new browsing context group and document**:

1. Let *group* be a new browsing context group[p965].
2. Append *group* to the user agent's browsing context group set[p965].
3. Let *browsingContext* and *document* be the result of creating a new browsing context and document[p962] with null, null, and *group*.

4. Append[p966] *browsingContext* to *group*.

5. Return *group* and *document*.

To **append** a top-level browsing context[p964] *browsingContext* to a browsing context group[p965] *group*:

1. Append *browsingContext* to *group*'s browsing context set[p965].

2. Set *browsingContext*'s group[p965] to *group*.

To **remove** a top-level browsing context[p964] *browsingContext*:

1. Assert: *browsingContext*'s group[p965] is non-null.

2. Let *group* be *browsingContext*'s group[p965].

3. Set *browsingContext*'s group[p965] to null.

4. Remove *browsingContext* from *group*'s browsing context set[p965].

5. If *group*'s browsing context set[p965] is empty, then remove *group* from the user agent's browsing context group set[p965].

Note

Append[p966] and remove[p966] are primitive operations that help define the lifetime of a browsing context group[p965]. They are called by higher-level creation and destruction operations for `Document`[p127]s and browsing contexts[p961].

When there are no `Document`[p127] objects whose browsing context[p961] equals a given browsing context[p961] (i.e., all such `Document`[p127]s have been destroyed[p1023]), and that browsing context[p961]'s `WindowProxy`[p904] is eligible for garbage collection, then the browsing context[p961] will never be accessed again. If it is a top-level browsing context[p964], then at this point the user agent must remove[p966] it.

7.3.3 Fully active documents §[p966]

A `Document`[p127] *d* is said to be **fully active** when *d* is the active document[p952] of a navigable[p952] *navigable*, and either *navigable* is a top-level traversable[p953] or *navigable*'s container document[p955] is fully active[p966].

Because they are associated with an element, child navigables[p955] are always tied to a specific `Document`[p127], their container document[p955], in their parent navigable[p952]. User agents must not allow the user to interact with child navigables[p955] whose container documents[p955] are not themselves fully active[p966].

Example

The following example illustrates how a `Document`[p127] can be the active document[p952] of its node navigable[p953], while not being fully active[p966]. Here `a.html` is loaded into a browser window, `b-1.html` starts out loaded into an `iframe`[p383] as shown, and `b-2.html` and `c.html` are omitted (they can simply be an empty document).

```
<!-- a.html -->
<!DOCTYPE html>
<html lang="en">
<title>Navigable A</title>

<iframe src="b-1.html"></iframe>
<button onclick="frames[0].location.href = 'b-2.html'">Click me</button>

<!-- b-1.html -->
<!DOCTYPE html>
<html lang="en">
<title>Navigable B</title>

<iframe src="c.html"></iframe>
```

At this point, the documents given by `a.html`, `b-1.html`, and `c.html` are all the active documents[p952] of their respective node

navigables[p953]. They are also all fully active[p966].

After clicking on the button[p556], and thus loading a new Document[p127] from `b-2.html` into navigable B, we have the following results:

- The `a.html` Document[p127] remains both the active document[p952] of navigable A, and fully active[p966].
- The `b-1.html` Document[p127] is now *not* the active document[p952] of navigable B. As such it is also not fully active[p966].
- The new `b-2.html` Document[p127] is now the active document[p952] of navigable B, and is also fully active[p966].
- The `c.html` Document[p127] is still the active document[p952] of navigable C. However, since C's container document[p955] is the `b-1.html` Document[p127], which is itself not fully active[p966], this means the `c.html` Document[p127] is now not fully active[p966].

7.4 Navigation and session history §[p967]

Welcome to the dragon's maw. Navigation, session history, and the traversal through that session history are some of the most complex parts of this standard.

The basic concept may not seem so difficult:

- The user is looking at a navigable[p952] that is presenting its active document[p952]. They navigate[p977] it to another URL.
- The browser fetches the given URL from the network, using it to populate[p992] a new session history entry[p968] with a newly-created[p1013] Document[p127].
- The browser updates the navigable[p952]'s active session history entry[p952] to the newly-populated one, and thus updates the active document[p952] that it is showing to the user.
- At some point later, the user presses the browser back button[p990] to go back to the previous session history entry[p968].
- The browser looks at the URL[p968] stored in that session history entry[p968], and uses it to re-fetch and populate[p992] that entry's document[p968].
- The browser again updates the navigable[p952]'s active session history entry[p952].

You can see some of the intertwined complexity peeking through here, in how traversal can cause a navigation (i.e., a network fetch to a stored URL), and how a navigation necessarily needs to interface with the session history list to ensure that when it finishes the user is looking at the right thing. But the real problems come in with the various edge cases and interacting web platform features:

- Child navigables[p955] (e.g., those contained in `iframe`[p383]s) can also navigate and traverse, but those navigations need to be linearized into a single session history list[p953] since the user only has a single back/forward interface for the entire traversable navigable[p953] (e.g., browser tab).
- Since the user can traverse back more than a single step in the session history (e.g., by holding down their back button), they can end up traversing multiple navigables[p952] at the same time when child navigables[p955] are involved. This needs to be synchronized across all of the involved navigables, which might involve multiple event loops[p1071] or even agent clusters.
- During navigation, servers can respond with 204 or 205 status codes or with `` `Content-Disposition: attachment` `` headers, which cause navigation to abort and the navigable[p952] to stay on its original active document[p961]. (This is much worse if it happens during a traversal-initiated navigation!)
- Various other HTTP headers, such as `` `Location` ``, `` `Refresh`[p1025] ``, `` `X-Frame-Options`[p1024] ``, and those for Content Security Policy, contribute to either the fetching process[p995], or the Document-creation process[p1013], or both. The `` `Cross-Origin-Opener-Policy`[p875] `` header even contributes to the browsing context selection and creation[p876] process!
- Some navigations (namely fragment navigations[p984] and single-page app navigations[p990]) are synchronous, meaning that JavaScript code expects to observe the navigation's results instantly. This then needs to be synchronized with the view of the session history that all other navigables[p952] in the tree see, which can be subject to race conditions and necessitate resolving conflicting views of the session history.

- The platform has accumulated various exciting navigation-related features that need special-casing, such as javascript:[p982] URLs, srcdoc[p384] iframe[p383]s, and the beforeunload[p1406] event.

In what follows, we have attempted to guide the reader through these complexities by appropriately cordoning them off into labeled sections and algorithms, and giving appropriate words of introduction where possible. Nevertheless, if you wish to truly understand navigation and session history, the usual advice[p30] will be invaluable.

7.4.1 Session history §[p968]

7.4.1.1 Session history entries §[p968]

A **session history entry** is a struct with the following items:

- **step**, a non-negative integer or "pending", initially "pending".
- **URL**, a URL
- **document state**, a document state[p969].
- **classic history API state**, which is serialized state[p968], initially StructuredSerializeForStorage[p120](null).
- **navigation API state**, which is a serialized state[p968], initially StructuredSerializeForStorage[p120](undefined).
- **navigation API key**, which is a string, initially set to the result of generating a random UUID.
- **navigation API ID**, which is a string, initially set to the result of generating a random UUID.
- **scroll restoration mode**, a scroll restoration mode[p969], initially "auto[p969]".
- **scroll position data**, which is scroll position data for the document[p968]'s restorable scrollable regions[p1013].
- **persisted user state**, which is implementation-defined, initially null

Example

For example, some user agents might want to persist the values of form controls.

Note

User agents that persist the value of form controls are encouraged to also persist their directionality (the value of the element's dir[p156] attribute). This prevents values from being displayed incorrectly after a history traversal when the user had originally entered the values with an explicit, non-default directionality.

To get a session history entry[p968]'s **document**, return its document state[p968]'s document[p969].

Serialized state is a serialization (via StructuredSerializeForStorage[p120]) of an object representing a user interface state. We sometimes informally refer to "state objects", which are the objects representing user interface state supplied by the author, or alternately the objects created by deserializing (via StructuredDeserialize[p120]) serialized state.

Pages can add[p917] serialized state[p968] to the session history. These are then deserialized[p120] and returned to the script[p1407] when the user (or script) goes back in the history, thus enabling authors to use the "navigation" metaphor even in one-page applications.

Note

Serialized state[p968] is intended to be used for two main purposes: first, storing a preparsed description of the state in the URL so that in the simple case an author doesn't have to do the parsing (though one would still need the parsing for handling URLs passed around by users, so it's only a minor optimization). Second, so that the author can store state that one wouldn't store in the URL because it only applies to the current Document[p127] instance and it would have to be reconstructed if a new Document[p127] were opened.

An example of the latter would be something like keeping track of the precise coordinate from which a popup div[p251] was made to animate, so that if the user goes back, it can be made to animate to the same location. Or alternatively, it could be used to keep a pointer into a cache of data that would be fetched from the server based on the information in the URL, so that when going back and forward, the information doesn't have to be fetched again.

A **scroll restoration mode** indicates whether the user agent should restore the persisted scroll position (if any) when traversing to an entry[p968]. A scroll restoration mode is one of the following:

"auto"

The user agent is responsible for restoring the scroll position upon navigation.

"manual"

The page is responsible for restoring the scroll position and the user agent does not attempt to do so automatically

7.4.1.2 Document state §[p969]

Document state holds state inside a session history entry[p968] regarding how to present and, if necessary, recreate, a `Document`[p127]. It has:

- A **document**, a `Document`[p127] or null, initially null.

  Note

  When a history entry is active[p952], it has a `Document`[p127] in its document state[p968]. However, when a `Document`[p127] is not fully active[p966], it's possible for it to be destroyed[p1023] to free resources. In such cases, this document[p969] item will be nulled out. The URL[p968] and other data in the session history entry[p968] and document state[p968] is then used to bring a new `Document`[p127] into being to take the place of the original, in the case where the user agent finds itself having to traverse to the entry.

  If the `Document`[p127] is not destroyed[p1023], then during history traversal[p990], it can be reactivated[p1010]. The cache in which browsers store such `Document`[p127]s is often called a back-forward cache, *or* bfcache *(or perhaps "blazingly fast" cache).*

- A **history policy container**, a policy container[p888] or null, initially null.
- A **request referrer**, which is "`no-referrer`", "`client`", or a URL, initially "`client`".
- A **request referrer policy**, which is a referrer policy, initially the default referrer policy.

  Note

  The request referrer policy[p969] is distinct from the history policy container[p969]'s referrer policy[p888]. The former is used for fetches of this document, whereas the latter controls fetches by this document.

- An **initiator origin**, which is an origin[p869] or null, initially null.
- An **origin**, which is an origin[p869] or null, initially null.

  Note

  This is the origin that we set "`about:`"-schemed `Document`[p127]s' origin to. We store it here because it is also used when restoring these `Document`[p127]s during traversal, since they are reconstructed locally without visiting the network. It is also used to compare the origin before and after the session history entry[p968] is repopulated[p992]. If the origins change, the navigable target name[p970] is cleared.

- An **about base URL**, which is a URL or null, initially null.

  Note

  This will be populated only for "`about:`"-schemed `Document`[p127]s and will be the fallback base URL[p94] for those `Document`[p127]s. It is a snapshot of the initiator `Document`[p127]'s document base URL[p94].

- **Nested histories**, a list of nested histories[p970], initially an empty list.
- A **resource**, a string, POST resource[p970] or null, initially null.

  Note

  A string is treated as HTML. It's used to store the source of an `iframe srcdoc` document[p384].

- A **reload pending** boolean, initially false.
- An **ever populated** boolean, initially false.

- A **navigable target name** string, initially the empty string.

User agents may destroy[p1023] the documents[p969] of document states[p969] with non-null documents[p969], as long as the `Document`[p127] is not fully active[p966].

Apart from that restriction, this standard does not specify when user agents should destroy the document[p969] stored in a document state[p969], versus keeping it cached.

A **POST resource** has:

- A **request body**, a byte sequence or failure.

  This is only ever accessed in parallel[p43], so it doesn't need to be stored in memory. However, it must return the same byte sequence each time. If this isn't possible due to resources changing on disk, or if resources can no longer be accessed, then this must be set to failure.

- A **request content-type**, which is `` `application/x-www-form-urlencoded` ``, `` `multipart/form-data`[p1409] ``, or `` `text/plain` ``.

A **nested history** has:

- An **id**, a unique internal value[p94].

  Note

  This is used to associate the nested history[p970] with a navigable[p952].

- **Entries**, a list of session history entries[p968].

This will later contain ways to identify a child navigable across reloads.

Several contiguous entries in a session history can share the same document state[p968]. This can occur when the initial entry is reached via normal navigation[p977], and the following entry is added via `history.pushState()`[p917]. Or it can occur via navigation to a fragment[p984].

Note

All entries that share the same document state[p968] (and that are therefore merely different states of one particular document) are contiguous by construction.

A `Document`[p127] has a **latest entry**, a session history entry[p968] or null.

Note

This is the entry that was most recently represented by a given `Document`[p127]. A single `Document`[p127] can represent many session history entries[p968] over time, as many contiguous session history entries[p968] can share the same document state[p968] as explained above.

7.4.1.3 Centralized modifications of session history §[p970]

To maintain a single source of truth, all modifications to a traversable navigable[p953]'s session history entries[p953] need to be synchronized. This is especially important due to how session history is influenced by all of the descendant navigables[p952], and thus by multiple event loops[p1071]. To accomplish this, we use the session history traversal parallel queue[p970] structure.

A **session history traversal parallel queue** is very similar to a parallel queue[p43]. It has an **algorithm set**, an ordered set.

The items in a session history traversal parallel queue[p970]'s algorithm set[p970] are either algorithm steps, or **synchronous navigation steps**, which are a particular brand of algorithm steps involving a **target navigable** (a navigable[p952]).

To **append session history traversal steps** to a traversable navigable[p953] *traversable* given algorithm steps *steps*, append *steps* to *traversable*'s session history traversal queue[p953]'s algorithm set[p970].

To **append session history synchronous navigation steps** involving a navigable[p952] *targetNavigable* to a traversable navigable[p953] *traversable* given algorithm steps *steps*, append *steps* as synchronous navigation steps[p970] targeting target navigable[p970] *targetNavigable* to *traversable*'s session history traversal queue[p953]'s algorithm set[p970].

To **start a new session history traversal parallel queue**:

1. Let *sessionHistoryTraversalQueue* be a new session history traversal parallel queue[p970].
2. Run the following steps in parallel[p43]:
    1. While true:
        1. If *sessionHistoryTraversalQueue*'s algorithm set[p970] is empty, then continue.
        2. Let *steps* be the result of dequeuing from *sessionHistoryTraversalQueue*'s algorithm set[p970].
        3. Run *steps*.
3. Return *sessionHistoryTraversalQueue*.

Synchronous navigation steps[p970] are tagged in the algorithm set[p970] to allow them to conditionally "jump the queue". This is handled within apply the history step[p1005].

Example

Imagine the joint session history depicted by this Jake diagram[p956]:

	0	1
top	/a	***/b***

And the following code runs at the top level:

```
history.back();
location.href = '#foo';
```

The desired result is:

	0	1	2
top	***/a***	/b	/b#foo

This isn't straightforward, as the sync navigation wins the race in terms of being observable, whereas the traversal wins the race in terms of queuing steps on the session history traversal parallel queue[p970]. To achieve this result, the following happens:

1. `history.back()`[p916] appends steps[p971] intended to traverse by a delta of −1.
2. `location.href = '#foo'`[p909] synchronously changes the active session history entry[p952] entry to a newly-created one, with the URL `/b#foo`, and appends synchronous steps[p971] to notify the central source of truth about that new entry. Note that this does *not* yet update the current session history entry[p952], current session history step[p953], or the session history entries[p953] list; those updates cannot be done synchronously, and instead must be done as part of the queued steps.
3. On the session history traversal parallel queue[p970], the steps queued by `history.back()`[p916] run:
    1. The target history step is determined to be 0: the current session history step[p953] (i.e., 1) plus the intended delta of −1.
    2. We enter the main apply the history step[p1002] algorithm.

        The entry at step 0, for the `/a` URL, has its document[p968] populated[p992].

        Meanwhile, the queue is checked for synchronous navigation steps[p970]. The steps queued by the `location.href`[p909] setter now run, and block the traversal from performing effects beyond document population (such as, unloading documents and switching active history entries) until they are finished. Those steps cause the following to happen:

1. The entry with URL `/b#foo` is added, with its step[p968] determined to be 2: the current session history step[p953] (i.e., 1) plus 1.

2. We fully switch to that newly added entry, including a nested call to apply the history step[p1002]. This ultimately results in updating the document[p1009] by dispatching events like `hashchange`[p1406].

Only once that is all complete, and the `/a` history entry has been fully populated with a document[p968], do we move on with applying the history step given the target step of 0.

At this point, the `Document`[p127] with URL `/b#foo` unloads[p1021], and we finish moving to our target history step 0, which makes the entry with URL `/a` become the active session history entry[p952] and 0 become the current session history step[p953].

Example

Here is another more complex example, involving races between populating two different `iframe`[p383]s, and a synchronous navigation once one of those iframes loads. We start with this setup:

	0	1	2
top	***/t***		
frames[0]	/i-0-a	***/i-0-b***	
frames[1]	/i-1-a		***/i-1-b***

and then call `history.go(-2)`[p916]. The following then occurs:

1. `history.go(-2)`[p916] appends steps[p971] intended to traverse by a delta of −2. Once those steps run:

    1. The target step is determined to be 2 + (−2) = 0.

    2. In parallel, the fetches are made to populate[p992] the two iframes, fetching `/i-0-a` and `/i-1-a` respectively.

       Meanwhile, the queue is checked for synchronous navigation steps[p970]. There aren't any right now.

    3. In the fetch race, the fetch for `/i-0-a` wins. We proceed onward to finish all of apply the history step[p1002]'s work for how the traversal impacts the `frames[0]` navigable[p952], including updating its active session history entry[p952] to the entry with URL `/i-0-a`.

    4. Before the fetch for `/i-1-a` finishes, we reach the point where scripts may run for the newly-created document[p1010] in the `frames[0]` navigable[p952]'s active document[p952]. Some such script does run:

       ```
       location.href = '#foo'
       ```

       This synchronously changes the `frames[0]` navigable's active session history entry[p952] entry to a newly-created one, with the URL `/i-0-a#foo`, and appends synchronous steps[p971] to notify the central source of truth about that new entry.

       Unlike in the previous example[p971], these synchronous steps do *not* "jump the queue" and update the traversable[p953] before we finish the fetch for `/i-1-a`. This is because the navigable in question, `frames[0]`, has already been altered as part of the traversal, so we know that with the current session history step[p953] being 2, adding the new entry as a step 3 doesn't make sense.

    5. Once the fetch for `/i-1-a` finally finishes, we proceed to finish updating the `frames[1]` navigable[p952] for the traversal, including updating its active session history entry[p952] to the entry with URL `/i-1-a`.

    6. Now that both navigables have finished processing the traversal, we update the current session history step[p953] to the target step of 0.

2. Now we can process the steps that were queued for the synchronous navigation:

    1. The `/i-0-a#foo` entry is added, with its step[p968] determined to be 1: the current session history step[p953] (i.e., 0) plus 1. This also clears existing forward history[p974].

    2. We fully switch to that newly added entry, including calling apply the history step[p1002]. This ultimately results in

updating the document[p1009] by dispatching events like hashchange[p1406], as well as updating the current session history step[p953] to the target step of 1.

The end result is:

	0	1
top	/t	
frames[0]	/i-0-a	/i-0-a#foo
frames[1]	/i-1-a	

7.4.1.4 Low-level operations on session history §[p973]

This section contains a miscellaneous grab-bag of operations that we perform throughout the standard when manipulating session history. The best way to get a sense of what they do is to look at their call sites.

To **get session history entries** of a navigable[p952] *navigable*:

1. Let *traversable* be *navigable*'s traversable navigable[p953].
2. Assert: this is running within *traversable*'s session history traversal queue[p953].
3. If *navigable* is *traversable*, return *traversable*'s session history entries[p953].
4. Let *docStates* be an empty ordered set of document states[p969].
5. For each *entry* of *traversable*'s session history entries[p953], append *entry*'s document state[p968] to *docStates*.
6. For each *docState* of *docStates*:
    1. For each *nestedHistory* of *docState*'s nested histories[p969]:
        1. If *nestedHistory*'s id[p970] equals *navigable*'s id[p952], return *nestedHistory*'s entries[p970].
        2. For each *entry* of *nestedHistory*'s entries[p970], append *entry*'s document state[p968] to *docStates*.
7. Assert: this step is not reached.

To **get session history entries for the navigation API** of a navigable[p952] *navigable* given an integer *targetStep*:

1. Let *rawEntries* be the result of getting session history entries[p973] for *navigable*.
2. Let *entriesForNavigationAPI* be a new empty list.
3. Let *startingIndex* be the index of the session history entry[p968] in *rawEntries* who has the greatest step[p968] less than or equal to *targetStep*.

    Note

    See this example[p1008] to understand why it's the greatest step less than or equal to targetStep.

4. Append *rawEntries*[*startingIndex*] to *entriesForNavigationAPI*.
5. Let *startingOrigin* be *rawEntries*[*startingIndex*]'s document state[p968]'s origin[p969].
6. Let *i* be *startingIndex* − 1.
7. While *i* > 0:
    1. If *rawEntries*[*i*]'s document state[p968]'s origin[p969] is not same origin[p870] with *startingOrigin*, then break.
    2. Prepend *rawEntries*[*i*] to *entriesForNavigationAPI*.
    3. Set *i* to *i* − 1.
8. Set *i* to *startingIndex* + 1.

9. While *i* < *rawEntries*'s size:
    1. If *rawEntries*[*i*]'s document state[p968]'s origin[p969] is not same origin[p870] with *startingOrigin*, then break.
    2. Append *rawEntries*[*i*] to *entriesForNavigationAPI*.
    3. Set *i* to *i* + 1.
10. Return *entriesForNavigationAPI*.

To **clear the forward session history** of a traversable navigable[p953] *navigable*:

1. Assert: this is running within *navigable*'s session history traversal queue[p953].
2. Let *step* be the *navigable*'s current session history step[p953].
3. Let *entryLists* be the ordered set « *navigable*'s session history entries[p953] ».
4. For each *entryList* of *entryLists*:
    1. Remove every session history entry[p968] from *entryList* that has a step[p968] greater than *step*.
    2. For each *entry* of *entryList*:
        1. For each *nestedHistory* of *entry*'s document state[p968]'s nested histories[p969], append *nestedHistory*'s entries list[p970] to *entryLists*.

To **get all used history steps** that are part of traversable navigable[p953] *traversable*:

1. Assert: this is running within *traversable*'s session history traversal queue[p953].
2. Let *steps* be an empty ordered set of non-negative integers.
3. Let *entryLists* be the ordered set « *traversable*'s session history entries[p953] ».
4. For each *entryList* of *entryLists*:
    1. For each *entry* of *entryList*:
        1. Append *entry*'s step[p968] to *steps*.
        2. For each *nestedHistory* of *entry*'s document state[p968]'s nested histories[p969], append *nestedHistory*'s entries list[p970] to *entryLists*.
5. Return *steps*, sorted.

7.4.2 Navigation §[p97 4]

Certain actions cause a navigable[p952] to *navigate*[p977] to a new resource.

Example

For example, following a hyperlink[p304], form submission[p619], and the `window.open()`[p896] and `location.assign()`[p912] methods can all cause navigation.

Note

Although in this standard the word "navigation" refers specifically to the navigate[p977] algorithm, this doesn't always line up with web developer or user perceptions. For example:

- *The URL and history update steps[p991] are often used during so-called "single-page app navigations" or "same-document navigations", but they do not trigger the navigate[p977] algorithm.*
- *Reloads[p990] and traversals[p990] are sometimes talked about as a type of navigation, since all three will often attempt to populate the history entry's document[p992] and thus could perform navigational fetches. See, e.g., the APIs exposed* Navigation Timing*. But they have their own entry point algorithms, separate from the navigate[p977] algorithm.*

[NAVIGATIONTIMING][p1415]

- *Although fragment navigations*[p984] *are always done through the navigate*[p977] *algorithm, a user might perceive them as more like jumping around a single page, than as a true navigation.*

7.4.2.1 Supporting concepts §[p975]

Before we can jump into the navigation algorithm[p977] itself, we need to establish several important structures that it uses.

The **source snapshot params** struct is used to capture data from a `Document`[p127] initiating a navigation. It is snapshotted at the beginning of a navigation and used throughout the navigation's lifetime. It has the following items:

has transient activation
: a boolean

sandboxing flags
: a sandboxing flag set[p885]

allows downloading
: a boolean

fetch client
: an environment settings object[p1032], only to be used as a request client

source policy container
: a policy container[p888]

To **snapshot source snapshot params** given a `Document`[p127] *sourceDocument*, return a new source snapshot params[p975] with

has transient activation[p975]
: true if *sourceDocument*'s relevant global object[p1039] has transient activation[p811]; otherwise false

sandboxing flags[p975]
: *sourceDocument*'s active sandboxing flag set[p887]

allows downloading[p975]
: false if *sourceDocument*'s active sandboxing flag set[p887] has the sandboxed downloads browsing context flag[p886] set; otherwise true

fetch client[p975]
: *sourceDocument*'s relevant settings object[p1039]

source policy container[p975]
: *sourceDocument*'s policy container[p128]

The **target snapshot params** struct is used to capture data from a navigable[p952] being navigated. Like source snapshot params[p975], it is snapshotted at the beginning of a navigation and used throughout the navigation's lifetime. It has the following items:

sandboxing flags
: a sandboxing flag set[p885]

To **snapshot target snapshot params** given a navigable[p952] *targetNavigable*, return a new target snapshot params[p975] with sandboxing flags[p975] set to the result of determining the creation sandboxing flags[p887] given *targetNavigable*'s active browsing context[p952] and *targetNavigable*'s container[p955].

Much of the navigation process is concerned with determining how to create a new `Document`[p127], which ultimately happens in the create and initialize a `Document` object[p1013] algorithm. The parameters to that algorithm are tracked via a **navigation params** struct, which has the following items:

id
: null or a navigation ID[p976]

navigable

the navigable[p952] to be navigated

request

null or a request that started the navigation

response

a response that ultimately was navigated to (potentially a network error)

fetch controller

null or a fetch controller

commit early hints

null or an algorithm accepting a `Document`[p127], once it has been created

COOP enforcement result

a cross-origin opener policy enforcement result[p876], used for reporting and potentially for causing a browsing context group switch[p876]

reserved environment

null or an environment[p1031] reserved for the new `Document`[p127]

origin

an origin[p869] to use for the new `Document`[p127]

policy container

a policy container[p888] to use for the new `Document`[p127]

final sandboxing flag set

a sandboxing flag set[p885] to impose on the new `Document`[p127]

cross-origin opener policy

a cross-origin opener policy[p874] to use for the new `Document`[p127]

navigation timing type

a `NavigationTimingType` used for creating the navigation timing entry for the new `Document`[p127]

about base URL

a URL or null used to populate the new `Document`[p127]'s about base URL[p128]

Note

Once a navigation params[p975] struct is created, this standard does not mutate any of its items. They are only passed onward to other algorithms.

A **navigation ID** is a UUID string generated during navigation. It is used to interface with the *WebDriver BiDi* specification as well as to track the ongoing navigation[p989]. [WEBDRIVERBIDI][p1418]

After `Document`[p127] creation, the relevant traversable navigable[p953]'s session history[p953] gets updated. The `NavigationHistoryBehavior`[p922] enumeration is used to indicate the desired type of session history update to the navigate[p977] algorithm. It is one of the following:

"**`push`**"

A regular navigation which adds a new session history entry[p968], and will clear the forward session history[p974].

"**`replace`**"

A navigation that will replace the active session history entry[p952].

"**`auto`**"

The default value, which will be converted very early in the navigate[p977] algorithm into "`push`[p976]" or "`replace`[p976]". Usually it becomes "`push`[p976]", but under certain circumstances[p978] it becomes "`replace`[p976]" instead.

A **history handling behavior** is a `NavigationHistoryBehavior`[p922] that is either "`push`[p976]" or "`replace`[p976]", i.e., that has been resolved away from any initial "`auto`[p976]" value.

The navigation must be a replace, given a URL *url* and a Document[p127] *document*, if either of the following conditions hold:

- *url*'s scheme is "javascript[p982]"; or
- *document*'s is initial about:blank[p128] is true

Note

Other cases that often, but not always, force a "replace[p976]" navigation are:

- *If the Document[p127] is not completely loaded[p1021]; or,*
- *If the target URL equals the Document[p127]'s URL.*

Various parts of the platform track whether a user is involved in a navigation. A **user navigation involvement** is one of the following:

"browser UI"
The navigation was initiated by the user via browser UI mechanisms.

"activation"
The navigation was initiated by the user via the activation behavior of an element.

"none"
The navigation was not initiated by the user.

For convenience at certain call sites, the **user navigation involvement** for an Event *event* is defined as follows:

1. Assert: this algorithm is being called as part of an activation behavior definition.
2. Assert: *event*'s type is "click".
3. If *event*'s isTrusted is initialized to true, then return "activation[p977]".
4. Return "none[p977]".

7.4.2.2 Beginning navigation §[p977]

To **navigate** a navigable[p952] *navigable* to a URL *url* using a Document[p127] *sourceDocument*, with an optional POST resource[p970], string, or null ***documentResource*** (default null), an optional response-or-null ***response*** (default null), an optional boolean ***exceptionsEnabled*** (default false), an optional NavigationHistoryBehavior[p922] ***historyHandling*** (default "auto[p976]"), an optional serialized state[p968]-or-null ***navigationAPIState*** (default null), an optional entry list[p622] or null ***formDataEntryList*** (default null), an optional referrer policy ***referrerPolicy*** (default the empty string), and an optional user navigation involvement[p977] ***userInvolvement*** (default "none[p977]"):

1. Let *cspNavigationType* be "form-submission" if *formDataEntryList* is non-null; otherwise "other".
2. Let *sourceSnapshotParams* be the result of snapshotting source snapshot params[p975] given *sourceDocument*.
3. Let *initiatorOriginSnapshot* be *sourceDocument*'s origin.
4. Let *initiatorBaseURLSnapshot* be *sourceDocument*'s document base URL[p94].
5. If *sourceDocument*'s node navigable[p953] is not allowed by sandboxing to navigate[p987] *navigable* given and *sourceSnapshotParams*, then:
    1. If *exceptionsEnabled* is true, then throw a "SecurityError" DOMException.
    2. Return.
6. Let *navigationId* be the result of generating a random UUID. [WEBCRYPTO][p1418]
7. If the surrounding agent is equal to *navigable*'s active document[p952]'s relevant agent[p1029], then continue these steps. Otherwise, queue a global task[p1073] on the navigation and traversal task source[p1081] given *navigable*'s active window[p952] to continue these steps.

Note

We do this because we are about to look at a lot of properties of navigable's *active document*[p952]*, which are in theory only accessible over in the appropriate event loop*[p1071]*. (But, we do not want to unconditionally queue a task, since — for example — same-event-loop fragment navigations*[p984] *need to take effect synchronously.)*

Another implementation strategy would be to replicate the relevant information across event loops, or into a canonical "browser process", so that it can be consulted without queueing a task. This could give different results than what we specify here in edge cases, where the relevant properties have changed over in the target event loop but not yet been replicated. Further testing is needed to determine which of these strategies best matches browser behavior, in such racy edge cases.

8. If *navigable*'s active document[p952]'s unload counter[p1021] is greater than 0, then invoke WebDriver BiDi navigation failed with a WebDriver BiDi navigation status whose id is *navigationId*, status is "canceled", and url is *url*, and return.

9. If *historyHandling* is "auto[p976]", then:

    1. If *url* equals *navigable*'s active document[p952]'s URL, and *initiatorOriginSnapshot* is same origin[p870] with *targetNavigable*'s active document[p952]'s origin, then set *historyHandling* to "replace[p976]".

    2. Otherwise, set *historyHandling* to "push[p976]".

10. If the navigation must be a replace[p977] given *url* and *navigable*'s active document[p952], then set *historyHandling* to "replace[p976]".

11. If all of the following are true:

    - *documentResource* is null;
    - *response* is null;
    - *url* equals *navigable*'s active session history entry[p952]'s URL[p968] with *exclude fragments* set to true; and
    - *url*'s fragment is non-null

    then:

    1. Navigate to a fragment[p984] given *navigable*, *url*, *historyHandling*, *userInvolvement*, *navigationAPIState*, and *navigationId*.

    2. Return.

12. If *navigable*'s parent[p952] is non-null, then set *navigable*'s is delaying load events[p952] to true.

13. Let *targetBrowsingContext* be *navigable*'s active browsing context[p952].

14. Let *targetSnapshotParams* be the result of snapshotting target snapshot params[p975] given *navigable*.

15. Invoke WebDriver BiDi navigation started with *targetBrowsingContext*, and a new WebDriver BiDi navigation status whose id is *navigationId*, status is "pending", and url is *url*.

16. If *navigable*'s ongoing navigation[p989] is "traversal", then:

    1. Invoke WebDriver BiDi navigation failed with *targetBrowsingContext* and a new WebDriver BiDi navigation status whose id is *navigationId*, status is "canceled", and url is *url*.

    2. Return.

Note

Any attempts to navigate a navigable[p952] *that is currently traversing*[p1002] *are ignored.*

17. Set the ongoing navigation[p989] for *navigable* to *navigationId*.

Note

This will have the effect of aborting other ongoing navigations of navigable*, since at certain points during navigation changes to the ongoing navigation*[p989] *will cause further work to be abandoned.*

18. If *url*'s scheme is "javascript[p982]", then:

    1. Queue a global task[p1073] on the navigation and traversal task source[p1081] given *navigable*'s active window[p952] to navigate to a javascript: URL[p982] given *navigable*, *url*, *historyHandling*, *initiatorOriginSnapshot*, and *cspNavigationType*.

2. Return.

19. If all of the following are true:

    - *userInvolvement* is not "`browser UI`[p977]";
    - *navigable*'s active document[p952]'s origin is same origin-domain[p870] with *sourceDocument*'s origin;
    - *navigable*'s active document[p952]'s is initial `about:blank`[p128] is false; and
    - *url*'s scheme is a fetch scheme

    then:

    1. Let *navigation* be *navigable*'s active window[p952]'s navigation API[p922].

    2. Let *entryListForFiring* be *formDataEntryList* if *documentResource* is a POST resource[p970]; otherwise, null.

    3. Let *navigationAPIStateForFiring* be *navigationAPIState* if *navigationAPIState* is not null; otherwise, StructuredSerializeForStorage[p120](undefined).

    4. Let *continue* be the result of firing a push/replace/reload `navigate` event[p944] at *navigation* with *navigationType*[p944] set to *historyHandling*, *isSameDocument*[p944] set to false, *userInvolvement*[p944] set to *userInvolvement*, *formDataEntryList*[p944] set to *entryListForFiring*, *destinationURL*[p944] set to *url*, and *navigationAPIState*[p944] set to *navigationAPIStateForFiring*.

    5. If *continue* is false, then return.

    Note

    It is possible for navigations with userInvolvement *of* "`browser UI`[p977]" *or initiated by a cross origin-domain*[p870] sourceDocument *to fire* `navigate`[p1407] *events, if they go through the earlier navigate to a fragment*[p984] *path.*

20. In parallel[p43], run these steps:

    1. Let *unloadPromptCanceled* be the result of checking if unloading is canceled[p987] for *navigable*'s active document[p952]'s inclusive descendant navigables[p957].

    2. If *unloadPromptCanceled* is true, or *navigable*'s ongoing navigation[p989] is no longer *navigationId*, then:

        1. Invoke WebDriver BiDi navigation failed with *targetBrowsingContext* and a new WebDriver BiDi navigation status whose id is *navigationId*, status is "`canceled`", and url is *url*.

        2. Abort these steps.

    3. Queue a global task[p1073] on the navigation and traversal task source[p1081] given *navigable*'s active window[p952] to abort[p1023] *navigable*'s active document[p952].

    4. Let *documentState* be a new document state[p969] with

       request referrer policy[p969]
       referrerPolicy
       initiator origin[p969]
       initiatorOriginSnapshot
       resource[p969]
       documentResource
       navigable target name[p970]
       navigable's target name[p953]

       Note

       The navigable target name[p970] *can get cleared under various conditions later in the navigation process, before the document state is finalized.*

    5. If *url* is `about:blank`[p53] or `about:srcdoc`[p94], then:

        1. Set *documentState*'s origin[p969] to *initiatorOriginSnapshot*.

        2. Set *documentState*'s about base URL[p969] to *initiatorBaseURLSnapshot*.

    6. Let *historyEntry* be a new session history entry[p968], with its URL[p968] set to *url* and its document state[p968] set to *documentState*.

    7. Let *navigationParams* be null.

8. If *response* is non-null:

Note

The navigate[p977] algorithm is only supplied with a response as part of the object[p394] and embed[p391] processing models, or for processing parts of multipart/x-mixed-replace responses[p1018] after the initial response.

1. Let *policyContainer* be the result of determining navigation params policy container[p888] given response's URL, null, a clone[p888] of the *sourceDocument*'s policy container[p128], *navigable*'s container document[p955]'s policy container[p128], and null.

2. Let *finalSandboxFlags* be the union of *targetSnapshotParams*'s sandboxing flags[p975] and *policyContainer*'s CSP list[p888]'s CSP-derived sandboxing flags[p887].

3. Let *responseOrigin* be the result of determining the origin[p964] given *response*'s URL, *finalSandboxFlags*, and *documentState*'s initiator origin[p969].

4. Let *coop* be a new cross-origin opener policy[p874].

5. Let *coopEnforcementResult* be a new cross-origin opener policy enforcement result[p876] with

   url[p876]
   response's URL
   origin[p876]
   responseOrigin
   cross-origin opener policy[p876]
   coop

6. Set *navigationParams* to a new navigation params[p975], with

   id[p975]
   navigationId
   navigable[p976]
   navigable
   request[p976]
   null
   response[p976]
   response
   fetch controller[p976]
   null
   commit early hints[p976]
   null
   COOP enforcement result[p976]
   coopEnforcementResult
   reserved environment[p976]
   null
   origin[p976]
   responseOrigin
   policy container[p976]
   policyContainer
   final sandboxing flag set[p976]
   finalSandboxFlags
   cross-origin opener policy[p976]
   coop
   navigation timing type[p976]
   "navigate"
   about base URL[p976]
   documentState's about base URL[p969]

9. Attempt to populate the history entry's document[p992] for *historyEntry*, given *navigable*, "navigate", *sourceSnapshotParams*, *targetSnapshotParams*, *navigationId*, *navigationParams*, *cspNavigationType*, with *allowPOST*[p992] set to true and *completionSteps*[p992] set to the following step:

   1. Append session history traversal steps[p971] to *navigable*'s traversable[p953] to finalize a cross-document navigation[p981] given *navigable*, *historyHandling*, and *historyEntry*.

7.4.2.3 Ending navigation §[p98]

Although the usual cross-document navigation case will first foray into populating a session history entry[p992] with a `Document`[p127], all navigations that don't get aborted will ultimately end up calling into one of the below algorithms.

7.4.2.3.1 The usual cross-document navigation case §[p98]

To **finalize a cross-document navigation** given a navigable[p952] *navigable*, history handling behavior[p976] *historyHandling*, and session history entry[p968] *historyEntry*:

1. Assert: this is running on *navigable*'s traversable navigable's[p953] session history traversal queue[p953].
2. Set *navigable*'s is delaying `load` events[p952] to false.
3. If *historyEntry*'s document[p968] is null, then return.

   Note

   This means that attempting to populate the history entry's document[p992] ended up not creating a document, as a result of e.g., the navigation being canceled by a subsequent navigation, a 204 No Content response, etc.

4. If all of the following are true:
   - *navigable*'s parent[p952] is null;
   - *historyEntry*'s document[p968]'s browsing context[p961] is not an auxiliary browsing context[p961] whose opener browsing context[p961] is non-null; and
   - *historyEntry*'s document[p968]'s origin is not *navigable*'s active document[p952]'s origin

   then set *historyEntry*'s document state[p968]'s navigable target name[p970] to the empty string.
5. Let *entryToReplace* be *navigable*'s active session history entry[p952] if *historyHandling* is "`replace`[p976]", otherwise null.
6. Let *traversable* be *navigable*'s traversable navigable[p953].
7. Let *targetStep* be null.
8. Let *targetEntries* be the result of getting session history entries[p973] for *navigable*.
9. If *entryToReplace* is null, then:
   1. Clear the forward session history[p974] of *traversable*.
   2. Set *targetStep* to *traversable*'s current session history step[p953] + 1.
   3. Set *historyEntry*'s step[p968] to *targetStep*.
   4. Append *historyEntry* to *targetEntries*.

   Otherwise:
   1. Replace *entryToReplace* with *historyEntry* in *targetEntries*.
   2. Set *historyEntry*'s step[p968] to *entryToReplace*'s step[p968].
   3. If *historyEntry*'s document state[p968]'s origin[p969] is same origin[p870] with *entryToReplace*'s document state[p968]'s origin[p969], then set *historyEntry*'s navigation API key[p968] to *entryToReplace*'s navigation API key[p968].
   4. Set *targetStep* to *traversable*'s current session history step[p953].
10. Apply the push/replace history step[p1002] *targetStep* to *traversable*.

7.4.2.3.2 The `javascript:` URL special case §[p982]

`javascript:`[p982] URLs have a dedicated label on the issue tracker documenting various problems with their specification.

To **navigate to a `javascript:` URL**, given a navigable[p952] *targetNavigable*, a URL *url*, a history handling behavior[p976] *historyHandling*, an origin[p869] *initiatorOrigin*, and a string *cspNavigationType*:

1. Assert: *historyHandling* is "`replace`[p976]".
2. Set the ongoing navigation[p989] for *targetNavigable* to null.
3. If *initiatorOrigin* is not same origin-domain[p870] with *targetNavigable*'s active document[p952]'s origin, then return.
4. Let *request* be a new request whose URL is *url*.

   Note

   This is a synthetic request solely for plumbing into the next step. It will never hit the network.

5. If the result of should navigation request of type be blocked by Content Security Policy? given *request* and *cspNavigationType* is "`Blocked`", then return. [CSP][p1411]
6. Let *newDocument* be the result of evaluating a `javascript:` URL[p983] given *targetNavigable*, *url*, and *initiatorOrigin*.
7. If *newDocument* is null, then return.

   Note

   In this case, some JavaScript code was executed, but no new `Document`[p127] was created, so we will not perform a navigation.

8. Assert: *initiatorOrigin* is *newDocument*'s origin.
9. Let *entryToReplace* be *targetNavigable*'s active session history entry[p952].
10. Let *oldDocState* be *entryToReplace*'s document state[p968].
11. Let *documentState* be a new document state[p969] with

    document[p969]
    newDocument
    history policy container[p969]
    a clone[p888] of the *oldDocState*'s history policy container[p969] if it is non-null; null otherwise
    request referrer[p969]
    oldDocState's request referrer[p969]
    request referrer policy[p969]
    oldDocState's request referrer policy[p969] or should this be the *referrerPolicy* that was passed to navigate[p977]?
    initiator origin[p969]
    initiatorOrigin
    origin[p969]
    initiatorOrigin
    about base URL[p969]
    oldDocState's about base URL[p969]
    resource[p969]
    null
    ever populated[p969]
    true
    navigable target name[p970]
    oldDocState's navigable target name[p970]

12. Let *historyEntry* be a new session history entry[p968], with

    URL[p968]
    entryToReplace's URL[p968]
    document state[p968]
    documentState

Note

For the URL[p968], we do not use url, i.e. the actual `javascript:`[p982] URL that the navigate[p977] algorithm was called with. This means `javascript:`[p982] URLs are never stored in session history, and so can never be traversed to.

13. Append session history traversal steps[p971] to *targetNavigable*'s traversable[p953] to finalize a cross-document navigation[p981] with *targetNavigable*, *historyHandling*, and *historyEntry*.

To **evaluate a `javascript:` URL** given a navigable[p952] *targetNavigable*, a URL *url*, and an origin[p869] *newDocumentOrigin*:

1. Let *urlString* be the result of running the URL serializer on *url*.
2. Let *encodedScriptSource* be the result of removing the leading "`javascript:`" from *urlString*.
3. Let *scriptSource* be the UTF-8 decoding of the percent-decoding of *encodedScriptSource*.
4. Let *settings* be *targetNavigable*'s active document[p952]'s relevant settings object[p1039].
5. Let *baseURL* be *settings*'s API base URL[p1032].
6. Let *script* be the result of creating a classic script[p1048] given *scriptSource*, *settings*, *baseURL*, and the default classic script fetch options[p1041].
7. Let *evaluationStatus* be the result of running the classic script[p1050] *script*.
8. Let *result* be null.
9. If *evaluationStatus* is a normal completion, and *evaluationStatus*.[[Value]] is a String, then set *result* to *evaluationStatus*.[[Value]].
10. Otherwise, return null.
11. Let *response* be a new response with

    URL
    targetNavigable's active document[p952]'s URL
    header list
    « (`Content-Type`[p96], `text/html;charset=utf-8`) »
    body
    the UTF-8 encoding of *result*, as a body

    Note

    The encoding to UTF-8 means that unpaired surrogates will not roundtrip, once the HTML parser decodes the response body.

12. Let *policyContainer* be *targetNavigable*'s active document[p952]'s policy container[p128].
13. Let *finalSandboxFlags* be *policyContainer*'s CSP list[p888]'s CSP-derived sandboxing flags[p887].
14. Let *coop* be *targetNavigable*'s active document[p952]'s cross-origin opener policy[p128].
15. Let *coopEnforcementResult* be a new cross-origin opener policy enforcement result[p876] with

    url[p876]
    url
    origin[p876]
    newDocumentOrigin
    cross-origin opener policy[p876]
    coop

16. Let *navigationParams* be a new navigation params[p975], with

    id[p975]
    navigationId
    navigable[p976]
    targetNavigable
    request[p976]
    null this will cause the referrer of the resulting `Document`[p127] to be null; is that correct?
    response[p976]
    response

fetch controller[p976]
null
commit early hints[p976]
null
COOP enforcement result[p976]
coopEnforcementResult
reserved environment[p976]
null
origin[p976]
newDocumentOrigin
policy container[p976]
policyContainer
final sandboxing flag set[p976]
finalSandboxFlags
cross-origin opener policy[p976]
coop
navigation timing type[p976]
"navigate"
about base URL[p976]
targetNavigable's active document[p952]'s about base URL[p128]

17. Return the result of loading an HTML document[p1017] given *navigationParams*.

7.4.2.3.3 Fragment navigations §[p984]

To **navigate to a fragment** given a navigable[p952] *navigable*, a URL *url*, a history handling behavior[p976] *historyHandling*, a user navigation involvement[p977] *userInvolvement*, a serialized state[p968]-or-null *navigationAPIState*, and a navigation ID[p976] *navigationId*:

1. Let *navigation* be *navigable*'s active window[p952]'s navigation API[p922].
2. Let *destinationNavigationAPIState* be *navigable*'s active session history entry[p952]'s navigation API state[p968].
3. If *navigationAPIState* is not null, then set *destinationNavigationAPIState* to *navigationAPIState*.
4. Let *continue* be the result of firing a push/replace/reload `navigate` event[p944] at *navigation* with *navigationType*[p944] set to *historyHandling*, *isSameDocument*[p944] set to true, *userInvolvement*[p944] set to *userInvolvement*, and *destinationURL*[p944] set to *url*, and *navigationAPIState*[p944] set to *destinationNavigationAPIState*.
5. If *continue* is false, then return.
6. Let *historyEntry* be a new session history entry[p968], with

   URL[p968]
   url
   document state[p968]
   navigable's active session history entry[p952]'s document state[p968]
   navigation API state[p968]
   destinationNavigationAPIState
   scroll restoration mode[p968]
   navigable's active session history entry[p952]'s scroll restoration mode[p968]

   Note

   For navigations peformed with `navigation.navigate()`[p930], the value provided by the `state`[p922] option is used for the new navigation API state[p968]. (This will set it to the serialization of undefined, if no value is provided for that option.) For other fragment navigations, including user-initiated ones, the navigation API state[p968] is carried over from the previous entry.

   The classic history API state[p968] is never carried over.

7. Let *entryToReplace* be *navigable*'s active session history entry[p952] if *historyHandling* is "`replace`[p976]", otherwise null.
8. Let *history* be *navigable*'s active document[p952]'s history object[p916].
9. Let *scriptHistoryIndex* be *history*'s index[p916].

10. Let *scriptHistoryLength* be *history*'s length[p916].

11. If *historyHandling* is "push[p976]", then:

    1. Set *history*'s state[p916] to null.

    2. Increment *scriptHistoryIndex*.

    3. Set *scriptHistoryLength* to *scriptHistoryIndex* + 1.

12. Set *navigable*'s active session history entry[p952] to *historyEntry*.

13. Update document for history step application[p1009] given *navigable*'s active document[p952], *historyEntry*, true, *scriptHistoryIndex*, and *scriptHistoryLength*.

    Note

    This algorithm will be called twice as a result of a single fragment navigation: once synchronously, where best-guess values scriptHistoryIndex *and* scriptHistoryLength *are set,* `history.state`[p916] *is nulled out, and various events are fired; and once asynchronously, where the final values for index and length are set,* `history.state`[p916] *remains untouched, and no events are fired.*

14. Update the navigation API entries for a same-document navigation[p925] given *navigation*, *historyEntry*, and *historyHandling*.

15. Scroll to the fragment[p1011] given *navigable*'s active document[p952].

    Note

    If the scrolling fails because the `Document`[p127] *is new and the relevant ID has not yet been parsed, then the second asynchronous call to update document for history step application[p1009] will take care of scrolling.*

16. Let *traversable* be *navigable*'s traversable navigable[p953].

17. Append the following session history synchronous navigation steps[p971] involving *navigable* to *traversable*:

    1. Finalize a same-document navigation[p985] given *traversable*, *navigable*, *historyEntry*, and *entryToReplace*.

    2. Invoke WebDriver BiDi fragment navigated with *navigable*'s active browsing context[p952] and a new WebDriver BiDi navigation status whose id is *navigationId*, url is *url*, and status is "`complete`".

To **finalize a same-document navigation** given a traversable navigable[p953] *traversable*, a navigable[p952] *targetNavigable*, a session history entry[p968] *targetEntry*, and session history entry[p968]-or-null *entryToReplace*:

Note

This is used by both fragment navigations[p984] and by the URL and history update steps[p991], which are the only synchronous updates to session history. By virtue of being synchronous, those algorithms are performed outside of the top-level traversable[p953]'s session history traversal queue[p953]. This puts them out of sync with the top-level traversable[p953]'s current session history step[p953], so this algorithm is used to resolve conflicts due to race conditions.

1. Assert: this is running on *traversable*'s session history traversal queue[p953].

2. If *targetNavigable*'s active session history entry[p952] is not *targetEntry*, then return.

3. Let *targetStep* be null.

4. Let *targetEntries* be the result of getting session history entries[p973] for *targetNavigable*.

5. If *entryToReplace* is null, then:

    1. Clear the forward session history[p974] of *traversable*.

    2. Set *targetStep* to *traversable*'s current session history step[p953] + 1.

    3. Set *targetEntry*'s step[p968] to *targetStep*.

    4. Append *targetEntry* to *targetEntries*.

    Otherwise:

    1. Replace *entryToReplace* with *targetEntry* in *targetEntries*.

2. Set *targetEntry*'s step[p968] to *entryToReplace*'s step[p968].

3. Set *targetStep* to *traversable*'s current session history step[p953].

6. Apply the push/replace history step[p1002] *targetStep* to *traversable*.

Note

This is done even for "replace[p976]" navigations, as it resolves race conditions across multiple synchronous navigations.

7.4.2.3.4 Non-fetch schemes and external software §[p986]

The input to attempt to create a non-fetch scheme document[p986] is the **non-fetch scheme navigation params** struct. It is a lightweight version of navigation params[p975] which only carries parameters relevant to the non-fetch scheme navigation case. It has the following items:

id

null or a navigation ID[p976]

navigable

the navigable[p952] experiencing the navigation

URL

a URL

target snapshot sandboxing flags

the target snapshot params[p975]'s sandboxing flags[p975] present during navigation

source snapshot has transient activation

a copy of the source snapshot params[p975]'s has transient activation[p975] boolean present during activation

initiator origin

an origin[p869] possibly for use in a user-facing prompt to confirm the invocation of an external software package

Note

This differs slightly from a document state[p968]'s initiator origin[p969] in that a non-fetch scheme navigation params[p986]'s initiator origin[p986] follows redirects up to the last fetch scheme URL in a redirect chain that ends in a non-fetch scheme URL.

navigation timing type

a `NavigationTimingType` used for creating the navigation timing entry for the new `Document`[p127]

To **attempt to create a non-fetch scheme document**, given a non-fetch scheme navigation params[p986] *navigationParams*:

1. Let *url* be *navigationParams*'s URL[p986].

2. Let *navigable* be *navigationParams*'s navigable[p986].

3. If *url* is to be handled using a mechanism that does not affect *navigable*, e.g., because *url*'s scheme is handled externally, then:

    1. Hand-off to external software[p986] given *url*, *navigable*, *navigationParams*'s target snapshot sandboxing flags[p986], *navigationParams*'s source snapshot has transient activation[p986], and *navigationParams*'s initiator origin[p986].

    2. Return null.

4. Handle *url* by displaying some sort of inline content, e.g., an error message because the specified scheme is not one of the supported protocols, or an inline prompt to allow the user to select a registered handler[p1113] for the given scheme. Return the result of displaying the inline content[p1019] given *navigable*, *navigationParams*'s id[p986], and *navigationParams*'s navigation timing type[p986].

Note

In the case of a registered handler being used, navigate[p977] will be invoked with a new URL.

To **hand-off to external software** given a URL or response *resource*, a navigable[p952] *navigable*, a sandboxing flag set[p885]

sandboxFlags, a boolean *hasTransientActivation*, and an origin[p869] *initiatorOrigin* user agents should:

1. If all of the following conditions hold:
    - *navigable* is not a top-level traversable[p953];
    - *sandboxFlags* has its sandboxed custom protocols navigation browsing context flag[p886] set; and
    - *sandboxFlags* has its sandboxed top-level navigation with user activation browsing context flag[p885] set, or *hasTransientActivation* is false

    then return without invoking the external software package.

    Note

    Navigation inside an iframe toward external software can be seen by users as a new popup or a new top-level navigation. That's why its is allowed in sandboxed `iframe`[p383] *only when one of* `allow-popups`[p886], `allow-top-navigation`[p886], `allow-top-navigation-by-user-activation`[p886], *or* `allow-top-navigation-to-custom-protocols`[p887] *is specified.*

2. Perform the appropriate handoff of *resource* while attempting to mitigate the risk that this is an attempt to exploit the target software. For example, user agents could prompt the user to confirm that *initiatorOrigin* is to be allowed to invoke the external software in question. In particular, if *hasTransientActivation* is false, then the user agent should not invoke the external software package without prior user confirmation.

    Example

    For example, there could be a vulnerability in the target software's URL handler which a hostile page would attempt to exploit by tricking a user into clicking a link.

7.4.2.4 Preventing navigation §[p987]

A couple of scenarios can intervene early in the navigation process and put the whole thing to a halt. This can be especially exciting when multiple navigables[p952] are navigating at the same time, due to a session history traversal.

A navigable[p952] *source* is **allowed by sandboxing to navigate** a second navigable[p952] *target*, given a source snapshot params[p975] *sourceSnapshotParams*, if the following steps return true:

1. If *source* is *target*, then return true.
2. If *source* is an ancestor of *target*, then return true.
3. If *target* is an ancestor of *source*, then:
    1. If *target* is not a top-level traversable[p953], then return true.
    2. If *sourceSnapshotParams*'s has transient activation[p975] is true, and *sourceSnapshotParams*'s sandboxing flags[p975]'s sandboxed top-level navigation with user activation browsing context flag[p885] is set, then return false.
    3. If *sourceSnapshotParams*'s has transient activation[p975] is false, and *sourceSnapshotParams*'s sandboxing flags[p975]'s sandboxed top-level navigation without user activation browsing context flag[p885] is set, then return false.
    4. Return true.
4. If *target* is a top-level traversable[p953]:
    1. If *source* is the one permitted sandboxed navigator[p885] of *target*, then return true.
    2. If *sourceSnapshotParams*'s sandboxing flags[p975]'s sandboxed navigation browsing context flag[p885] is set, then return false.
    3. Return true.
5. If *sourceSnapshotParams*'s sandboxing flags[p975]'s sandboxed navigation browsing context flag[p885] is set, then return false.
6. Return true.

To **check if unloading is canceled** for a list of navigables[p952] *navigablesThatNeedBeforeUnload*, given an optional traversable

navigable[p953] *traversable*, an optional integer *targetStep*, and an optional user navigation involvement[p977]-or-null *userInvolvementForNavigateEvent*, run these steps. They return "`canceled-by-beforeunload`", "`canceled-by-navigate`", or "`continue`".

1. Let *documentsToFireBeforeunload* be the active document[p952] of each item in *navigablesThatNeedBeforeUnload*.
2. Let *unloadPromptShown* be false.
3. Let *finalStatus* be "`continue`".
4. If *traversable* was given, then:
    1. Assert: *targetStep* and *userInvolvementForNavigateEvent* were given.
    2. Let *targetEntry* be the result of getting the target history entry[p1008] given *traversable* and *targetStep*.
    3. If *targetEntry* is not *traversable*'s current session history entry[p952], and *targetEntry*'s document state[p968]'s origin[p969] is the same[p870] as *traversable*'s current session history entry[p952]'s document state[p968]'s origin[p969], then:

        Note

        In this case, we're going to fire the `navigate`[p1407] *event for* traversable *here. Because under some circumstances*[p945] *it might be canceled, we need to do this separately from other traversal* `navigate` *events*[p0]*, which happen later.*

        Additionally, because we want `beforeunload`[p1406] *events to fire before* `navigate`[p1407] *events, this means we need to fire* `beforeunload`[p1406] *for* traversable *here (if applicable), instead of doing it as part of the below loop over* documentsToFireBeforeunload*.*

        1. Assert: *userInvolvementForNavigateEvent* is not null.
        2. Let *eventsFired* be false.
        3. Let *needsBeforeunload* be true if *navigablesThatNeedBeforeUnload* contains *traversable*; otherwise false.
        4. If *needsBeforeunload* is true, then remove *traversable*'s active document[p952] from *documentsToFireBeforeunload*.
        5. Queue a global task[p1073] on the navigation and traversal task source[p1081] given *traversable*'s active window[p952] to perform the following steps:
            1. If *needsBeforeunload* is true, then:
                1. Let (*unloadPromptShownForThisDocument*, *unloadPromptCanceledByThisDocument*) be the result of running the steps to fire `beforeunload`[p989] given *traversable*'s active document[p952] and false.
                2. If *unloadPromptShownForThisDocument* is true, then set *unloadPromptShown* to true.
                3. If *unloadPromptCanceledByThisDocument* is true, then set *finalStatus* to "`canceled-by-beforeunload`".
            2. If *finalStatus* is "`canceled-by-beforeunload`", then abort these steps.
            3. Let *navigation* be *traversable*'s active window[p952]'s navigation API[p922].
            4. Let *navigateEventResult* be the result of firing a traverse `navigate` event[p943] at a `Navigation`[p922] *navigation* given *targetEntry* and *userInvolvementForNavigateEvent*.
            5. If *navigateEventResult* is false, then set *finalStatus* to "`canceled-by-navigate`".
            6. Set *eventsFired* to true.
        6. Wait until *eventsFired* is true.
        7. If *finalStatus* is not "`continue`", then return *finalStatus*.
5. Let *totalTasks* be the size of *documentsThatNeedBeforeunload*.

6. Let *completedTasks* be 0.
7. For each *document* of *documents*, queue a global task[p1073] on the navigation and traversal task source[p1081] given *document*'s relevant global object[p1039] to run the steps:
    1. Let (*unloadPromptShownForThisDocument*, *unloadPromptCanceledByThisDocument*) be the result of running the steps to fire `beforeunload`[p989] given *document* and *unloadPromptShown*.
    2. If *unloadPromptShownForThisDocument* is true, then set *unloadPromptShown* to true.
    3. If *unloadPromptCanceledByThisDocument* is true, then set *finalStatus* to "`canceled-by-beforeunload`".
    4. Increment *completedTasks*.
8. Wait for *completedTasks* to be *totalTasks*.
9. Return *finalStatus*.

The **steps to fire `beforeunload`** given a `Document`[p127] *document* and a boolean *unloadPromptShown* are:

1. Let *unloadPromptCanceled* be false.
2. Increase the *document*'s unload counter[p1021] by 1.
3. Increase *document*'s relevant agent[p1029]'s event loop[p1071]'s termination nesting level[p1021] by 1.
4. Let *eventFiringResult* be the result of firing an event named `beforeunload`[p1406] at *document*'s relevant global object[p1039], using `BeforeUnloadEvent`[p951], with the `cancelable` attribute initialized to true.
5. Decrease *document*'s relevant agent[p1029]'s event loop[p1071]'s termination nesting level[p1021] by 1.
6. If all of the following are true:
    - *unloadPromptShown* is false;
    - *document*'s active sandboxing flag set[p887] does not have its sandboxed modals flag[p886] set;
    - *document*'s relevant global object[p1039] has sticky activation[p811];
    - *eventFiringResult* is false, or the `returnValue`[p951] attribute of *event* is not the empty string; and
    - showing an unload prompt is unlikely to be annoying, deceptive, or pointless

    then:
    1. Set *unloadPromptShown* to true.
    2. Invoke WebDriver BiDi user prompt opened with *document*'s relevant global object[p1039], "`beforeunload`", and "".
    3. Ask the user to confirm that they wish to unload the document, and pause[p1080] while waiting for the user's response.

    Note

    The message shown to the user is not customizable, but instead determined by the user agent. In particular, the actual value of the `returnValue`[p951] attribute is ignored.

    4. If the user did not confirm the page navigation, set *unloadPromptCanceled* to true.
    5. Invoke WebDriver BiDi user prompt closed with *document*'s relevant global object[p1039] and true if *unloadPromptCanceled* is false or false otherwise.
7. Decrease *document*'s unload counter[p1021] by 1.
8. Return (*unloadPromptShown*, *unloadPromptCanceled*).

7.4.2.5 Aborting navigation §[p989]

Each navigable[p952] has an **ongoing navigation**, which is a navigation ID[p976], "`traversal`", or null, initially null. It is used to track navigation aborting and to prevent any navigations from taking place during traversal[p1002].

To **set the ongoing navigation** for a navigable[p952] *navigable* to *newValue*:

1. If *navigable*'s ongoing navigation[p989] is equal to *newValue*, then return.
2. Inform the navigation API about aborting navigation[p937] given *navigable*.
3. Set *navigable*'s ongoing navigation[p989] to *newValue*.

7.4.3 Reloading and traversing §[p990]

To **reload** a navigable[p952] *navigable* given an optional serialized state[p968]-or-null ***navigationAPIState*** (default null) and an optional user navigation involvement[p977] ***userInvolvement*** (default "`none`[p977]"):

1. If *userInvolvement* is not "`browser UI`[p977]", then:
    1. Let *navigation* be *navigable*'s active window[p952]'s navigation API[p922].
    2. Let *destinationNavigationAPIState* be *navigable*'s active session history entry[p952]'s navigation API state[p968].
    3. If *navigationAPIState* is not null, then set *destinationNavigationAPIState* to *navigationAPIState*.
    4. Let *continue* be the result of firing a push/replace/reload `navigate` event[p944] at *navigation* with *navigationType*[p944] set to "`reload`[p924]", *isSameDocument*[p944] set to false, *userInvolvement*[p944] set to *userInvolvement*, and *destinationURL*[p944] set to *navigable*'s active session history entry[p952]'s URL[p968], and *navigationAPIState*[p944] set to *destinationNavigationAPIState*.
    5. If *continue* is false, then return.
2. Set *navigable*'s active session history entry[p952]'s document state[p968]'s reload pending[p969] to true.
3. Let *traversable* be *navigable*'s traversable navigable[p953].
4. Append the following session history traversal steps[p971] to *traversable*:
    1. Apply the reload history step[p1002] to *traversable*.

To **traverse the history by a delta** given a traversable navigable[p953] *traversable*, an integer *delta*, and an optional `Document`[p127] ***sourceDocument***:

1. Let *sourceSnapshotParams* and *initiatorToCheck* be null.
2. Let *userInvolvement* be "`browser UI`[p977]".
3. If *sourceDocument* is given, then:
    1. Set *sourceSnapshotParams* to the result of snapshotting source snapshot params[p975] given *sourceDocument*.
    2. Set *initiatorToCheck* to *sourceDocument*'s node navigable[p953].
    3. Set *userInvolvement* to "`none`[p977]".
4. Append the following session history traversal steps[p971] to *traversable*:
    1. Let *allSteps* be the result of getting all used history steps[p974] for *traversable*.
    2. Let *currentStepIndex* be the index of *traversable*'s current session history step[p953] within *allSteps*.
    3. Let *targetStepIndex* be *currentStepIndex* plus *delta*.
    4. If *allSteps*[*targetStepIndex*] does not exist, then abort these steps.
    5. Apply the traverse history step[p1002] *allSteps*[*targetStepIndex*] to *traversable*, given *sourceSnapshotParams*, *initiatorToCheck*, and *userInvolvement*.

7.4.4 Non-fragment synchronous "navigations" §[p990]

Apart from the navigate[p977] algorithm, session history entries[p968] can be pushed or replaced via one more mechanism, the URL and

history update steps[p991]. The most well-known callers of these steps are the `history.replaceState()`[p917] and `history.pushState()`[p917] APIs, but various other parts of the standard also need to perform updates to the active history entry[p952], and they use these steps to do so.

The **URL and history update steps**, given a `Document`[p127] *document*, a URL *newURL*, an optional serialized state[p968]-or-null ***serializedData*** (default null), and an optional history handling behavior[p976] ***historyHandling*** (default "`replace`[p976]"), are:

1. Let *navigable* be *document*'s node navigable[p953].
2. Let *activeEntry* be *navigable*'s active session history entry[p952].
3. Let *newEntry* be a new session history entry[p968], with

   URL[p968]
   newURL
   serialized state[p968]
   if *serializedData* is not null, *serializedData*; otherwise *activeEntry*'s classic history API state[p968]
   document state[p968]
   activeEntry's document state[p968]
   scroll restoration mode[p968]
   activeEntry's scroll restoration mode[p968]
   persisted user state[p968]
   activeEntry's persisted user state[p968]
4. If *document*'s is initial `about:blank`[p128] is true, then set *historyHandling* to "`replace`[p976]".

   Note
   This means that `pushState()`[p917] on an initial `about:blank`[p128] `Document`[p127] behaves as a `replaceState()`[p917] call.
5. Let *entryToReplace* be *activeEntry* if *historyHandling* is "`replace`[p976]", otherwise null.
6. If *historyHandling* is "`push`[p976]", then:
   1. Increment *document*'s history object[p916]'s index[p916].
   2. Set *document*'s history object[p916]'s length[p916] to its index[p916] + 1.

   Note
   These are temporary best-guess values for immediate synchronous access.
7. If *serializedData* is not null, then restore the history object state[p1010] given *document* and *newEntry*.
8. Set *document*'s URL to *newURL*.

   Note
   Since this is neither a navigation[p977] nor a history traversal[p990], it does not cause a `hashchange`[p1406] event to be fired.
9. Set *document*'s latest entry[p970] to *newEntry*.
10. Set *navigable*'s active session history entry[p952] to *newEntry*.
11. Update the navigation API entries for a same-document navigation[p925] given *document*'s relevant global object[p1039]'s navigation API[p922], *newEntry*, and *historyHandling*.
12. Let *traversable* be *navigable*'s traversable navigable[p953].
13. Append the following session history synchronous navigation steps[p971] involving *navigable* to *traversable*:
    1. Finalize a same-document navigation[p985] given *traversable*, *navigable*, *newEntry*, and *entryToReplace*.

Note
Although both fragment navigation[p984] and the URL and history update steps[p991] perform synchronous history updates, only fragment navigation contains a synchronous call to update document for history step application[p1009]. The URL and history update steps[p991] instead perform a few select updates inside the above algorithm, omitting others. This is somewhat of an unfortunate historical accident, and generally leads to web-developer sadness about the inconsistency. For example, this means that `popstate`[p1407] events fire for fragment navigations, but not for `history.pushState()`[p917] calls.

7.4.5 Populating a session history entry §[p992]

As explained in the overview[p967], both navigation[p974] and traversal[p990] involve creating a session history entry[p968] and then attempting to populate its document[p968] member, so that it can be presented inside the navigable[p952].

This involves either: using an already-given response[p980]; using the srcdoc resource[p969] stored in the session history entry[p968]; or fetching[p995]. The process has several failure modes, which can either result in doing nothing (leaving the navigable[p952] on its currently-active[p952] `Document`[p127]) or can result in populating the session history entry[p968] with an error document[p1019].

To **attempt to populate the history entry's document** for a session history entry[p968] *entry*, given a navigable[p952] *navigable*, a `NavigationTimingType` *navTimingType*, a source snapshot params[p975] *sourceSnapshotParams*, a target snapshot params[p975] *targetSnapshotParams*, an optional navigation ID[p976]-or-null *navigationId* (default null), an optional navigation params[p975]-or-null *navigationParams* (default null), an optional string *cspNavigationType* (default "`other`"), an optional boolean ***allowPOST*** (default false), and optional algorithm steps ***completionSteps*** (default an empty algorithm):

1. Assert: this is running in parallel[p43].
2. Assert: if *navigationParams* is non-null, then *navigationParams*'s response[p976] is non-null.
3. Let *currentBrowsingContext* be *navigable*'s active browsing context[p952].
4. Let *documentResource* be *entry*'s document state[p968]'s resource[p969].
5. If *navigationParams* is null, then:
    1. If *documentResource* is a string, then set *navigationParams* to the result of creating navigation params from a srcdoc resource[p994] given *entry*, *navigable*, *targetSnapshotParams*, *navigationId*, and *navTimingType*.
    2. Otherwise, if both of the following are true:
        - *entry*'s URL[p968]'s scheme is a fetch scheme; and
        - *documentResource* is null, or *allowPOST* is true and *documentResource*'s request body[p970] is not failure

        then set *navigationParams* to the result of creating navigation params by fetching[p995] given *entry*, *navigable*, *sourceSnapshotParams*, *targetSnapshotParams*, *cspNavigationType*, *navigationId*, and *navTimingType*.
    3. Otherwise, if *entry*'s URL[p968]'s scheme is not a fetch scheme, then set *navigationParams* to a new non-fetch scheme navigation params[p986], with

        id[p986]
        navigationId
        navigable[p986]
        navigable
        URL[p986]
        entry's URL[p968]
        target snapshot sandboxing flags[p986]
        targetSnapshotParams's sandboxing flags[p975]
        source snapshot has transient activation[p986]
        sourceSnapshotParams's has transient activation[p975]
        initiator origin[p986]
        entry's document state[p968]'s initiator origin[p969]
        navigation timing type[p986]
        navTimingType
6. Queue a global task[p1073] on the navigation and traversal task source[p1081], given *navigable*'s active window[p961], to run these steps:
    1. If *navigable*'s ongoing navigation[p989] no longer equals *navigationId*, then run *completionSteps* and return.
    2. Let *failure* be false.
    3. If *navigationParams* is a non-fetch scheme navigation params[p986], then set *entry*'s document state[p968]'s document[p969] to the result of running attempt to create a non-fetch scheme document[p986] given *navigationParams*.

        Note
        The entry's URL[p968] might have been changed within the previous step of this algorithm following an HTTP

redirect.

4. Otherwise, if *navigationParams* is null, then set *failure* to true.

5. Otherwise, if the result of should navigation response to navigation request of type in target be blocked by Content Security Policy? given *navigationParams*'s request[p976], *navigationParams*'s response[p976], *navigationParams*'s policy container[p976]'s CSP list[p888], *cspNavigationType*, and *navigable* is "`Blocked`", then set *failure* to true. [CSP][p1411]

6. Otherwise, if *navigationParams*'s reserved environment[p976] is non-null and the result of checking a navigation response's adherence to its embedder policy[p884] given *navigationParams*'s response[p976], *navigable*, and *navigationParams*'s policy container[p976]'s embedder policy[p888] is false, then set *failure* to true.

7. Otherwise, if the result of checking a navigation response's adherence to `X-Frame-Options`[p1024] given *navigationParams*'s response[p976], *navigable*, *navigationParams*'s policy container[p976]'s CSP list[p888], and *navigationParams*'s origin[p976] is false, then set *failure* to true.

8. If *failure* is true, then:

    1. Set *entry*'s document state[p968]'s document[p969] to the result of creating a document for inline content that doesn't have a DOM[p1019], given *navigable*, null, and *navTimingType*. The inline content should indicate to the user the sort of error that occurred.

    2. Set *entry*'s document state[p968]'s document[p969]'s *salvageable*[p1021] to false.

    3. If *navigationParams* is not null, then:

        1. Run the environment discarding steps[p1032] for *navigationParams*'s reserved environment[p976].

        2. Invoke WebDriver BiDi navigation failed with *currentBrowsingContext* and a new WebDriver BiDi navigation status whose id is *navigationId*, status is "`canceled`", and url is *navigationParams*'s response[p976]'s URL.

9. Otherwise, if *navigationParams*'s response[p976]'s status is 204 or 205, then:

    1. Run *completionSteps*.

    2. Return.

10. Otherwise, if *navigationParams*'s response[p976] has a `Content-Disposition` header specifying the `attachment` disposition type, then:

    1. Let *sourceAllowsDownloading* be *sourceSnapshotParams*'s allows downloading[p975].

    2. Let *targetAllowsDownloading* be false if *navigationParams*'s final sandboxing flag set[p976] has the sandboxed downloads browsing context flag[p886] set; otherwise true.

    3. Let *uaAllowsDownloading* be true.

    4. Optionally, the user agent may set *uaAllowsDownloading* to false, if it believes doing so would safeguard the user from a potentially hostile download.

    5. If *sourceAllowsDownloading*, *targetAllowsDownloading*, and *uaAllowsDownloading* are true, then:

        1. Handle *navigationParams*'s response[p976] as a download[p305].

        2. Invoke WebDriver BiDi download started with *currentBrowsingContext* and a new WebDriver BiDi navigation status whose id is *navigationId*, status is "`complete`", and url is *navigationParams*'s response[p976]'s URL.

    6. Run *completionSteps*.

    7. Return.

11. Otherwise:

    1. Let *document* be the result of loading a document[p1001] given *navigationParams*, *sourceSnapshotParams*, and *entry*'s document state[p968]'s initiator origin[p969].

    2. If *document* is null, then run *completionSteps* and return.

3. Set *entry*'s document state[p968]'s document[p969] to *document*.
4. Set *entry*'s document state[p968]'s origin[p969] to *document*'s origin.
5. If *document*'s URL requires storing the policy container in history[p888], then set *entry*'s document state[p968]'s history policy container[p969] to *navigationParams*'s policy container[p976].

12. If *entry*'s document state[p968]'s request referrer[p969] is "`client`", then set it to *request*'s referrer.

    Note

    This ensures that if we traverse back entry *and have to refetch, we use the same referrer, instead of deriving the referrer from the fetch client.*

13. If *entry*'s document state[p968]'s document[p969] is not null, then set *entry*'s document state[p968]'s ever populated[p969] to true.
14. Run *completionSteps*.

To **create navigation params from a srcdoc resource** given a session history entry[p968] *entry*, a navigable[p952] *navigable*, a target snapshot params[p975] *targetSnapshotParams*, a navigation ID[p976]-or-null *navigationId*, and a `NavigationTimingType` *navTimingType*:

1. Let *documentResource* be *entry*'s document state[p968]'s resource[p969].
2. Let *response* be a new response with

   URL
   `about:srcdoc`[p94]
   header list
   « (`Content-Type`[p96], `text/html`) »
   body
   the UTF-8 encoding of *documentResource*, as a body

3. Let *responseOrigin* be the result of determining the origin[p964] given *response*'s URL, *targetSnapshotParams*'s sandboxing flags[p975], and *entry*'s document state[p968]'s origin[p969].
4. Let *coop* be a new cross-origin opener policy[p874].
5. Let *coopEnforcementResult* be a new cross-origin opener policy enforcement result[p876] with

   url[p876]
   response's URL
   origin[p876]
   responseOrigin
   cross-origin opener policy[p876]
   coop

6. Let *policyContainer* be the result of determining navigation params policy container[p888] given *response*'s URL, *entry*'s document state[p968]'s history policy container[p969], null, *navigable*'s container document[p955]'s policy container[p128], and null.
7. Return a new navigation params[p975], with

   id[p975]
   navigationId
   navigable[p976]
   navigable
   request[p976]
   null
   response[p976]
   response
   fetch controller[p976]
   null
   commit early hints[p976]
   null
   COOP enforcement result[p976]
   coopEnforcementResult
   reserved environment[p976]
   null

coop
navigation timing type[p976]
navTimingType
about base URL[p976]
entry's document state[p968]'s about base URL[p969]

To **create navigation params by fetching** given a session history entry[p968] *entry*, a navigable[p952] *navigable*, a source snapshot params[p975] *sourceSnapshotParams*, a target snapshot params[p975] *targetSnapshotParams*, a string *cspNavigationType*, a navigation ID[p976]-or-null *navigationId*, and a `NavigationTimingType` *navTimingType*, perform the following steps. They return a navigation params[p975], a non-fetch scheme navigation params[p986], or null.

Note

This algorithm mutates entry.

1. Assert: this is running in parallel[p43].
2. Let *documentResource* be *entry*'s document state[p968]'s resource[p969].
3. Let *request* be a new request, with

   url
   entry's URL[p968]
   client
   sourceSnapshotParams's fetch client[p975]
   destination
   "`document`"
   credentials mode
   "`include`"
   use-URL-credentials flag
   set
   redirect mode
   "`manual`"
   replaces client id
   navigable's active document[p952]'s relevant settings object[p1039]'s id[p1031]
   mode
   "`navigate`"
   referrer
   entry's document state[p968]'s request referrer[p969]
   referrer policy
   entry's document state[p968]'s request referrer policy[p969]
4. If *documentResource* is a POST resource[p970], then:
   1. Set *request*'s method to `POST`.
   2. Set *request*'s body to *documentResource*'s request body[p970].
   3. Set `Content-Type` to *documentResource*'s request content-type[p970] in *request*'s header list.
5. If *entry*'s document state[p968]'s reload pending[p969] is true, then set *request*'s reload-navigation flag.
6. Otherwise, if *entry*'s document state[p968]'s ever populated[p969] is true, then set *request*'s history-navigation flag.
7. If *sourceSnapshotParams*'s has transient activation[p975] is true, then set *request*'s user-activation to true.
8. If *navigable*'s container[p955] is non-null:
   1. If the *navigable*'s container[p955] has a browsing context scope origin[p1000], then set *request*'s origin to that browsing context scope origin[p1000].

2. Set *request*'s destination to *navigable*'s container[p955]'s local name.

3. If *sourceSnapshotParams*'s fetch client[p975] is *navigable*'s container document[p955]'s relevant settings object[p1039], then set *request*'s initiator type to *navigable*'s container[p955]'s local name.

   Note

   This ensure that only container-initiated navigations are reported to resource timing.

9. Let *response* be null.

10. Let *responseOrigin* be null.

11. Let *fetchController* be null.

12. Let *coopEnforcementResult* be a new cross-origin opener policy enforcement result[p876], with

    url[p876]
    navigable's active document[p952]'s URL
    origin[p876]
    navigable's active document[p952]'s origin
    cross-origin opener policy[p876]
    navigable's active document[p952]'s cross-origin opener policy[p128]
    current context is navigation source[p876]
    true if *navigable*'s active document[p952]'s origin is same origin[p870] with *entry*'s document state[p968]'s initiator origin[p969] otherwise false

13. Let *finalSandboxFlags* be an empty sandboxing flag set[p885].

14. Let *responsePolicyContainer* be null.

15. Let *responseCOOP* be a new cross-origin opener policy[p874].

16. Let *locationURL* be null.

17. Let *currentURL* be *request*'s current URL.

18. Let *commitEarlyHints* be null.

19. While true:

    1. If *request*'s reserved client is not null and *currentURL*'s origin is not the same[p870] as *request*'s reserved client's creation URL[p1031]'s origin, then:

       1. Run the environment discarding steps[p1032] for *request*'s reserved client.

       2. Set *request*'s reserved client to null.

       3. Set *commitEarlyHints* to null.

       Note

       Preloaded links from early hint headers[p182] remain in the preload cache after a same origin[p870] redirect, but get discarded when the redirect is cross-origin.

    2. If *request*'s reserved client is null, then:

       1. Let *topLevelCreationURL* be *currentURL*.

       2. Let *topLevelOrigin* be null.

       3. If *navigable* is not a top-level traversable[p953], then:

          1. Let *parentEnvironment* be *navigable*'s parent[p952]'s active document[p952]'s relevant settings object[p1039].

          2. Set *topLevelCreationURL* to *parentEnvironment*'s top-level creation URL[p1031].

          3. Set *topLevelOrigin* to *parentEnvironment*'s top-level origin[p1031].

       4. Set *request*'s reserved client to a new environment[p1031] whose id[p1031] is a unique opaque string, target browsing context[p1032] is *navigable*'s active browsing context[p952], creation URL[p1031] is *currentURL*, top-level

creation URL[p1031] is *topLevelCreationURL*, and top-level origin[p1031] is *topLevelOrigin*.

> **Note**
> *The created environment's active service worker[p1032] is set in the Handle Fetch algorithm during the fetch if the request URL matches a service worker registration. [SW][p1417]*

3. If the result of should navigation request of type be blocked by Content Security Policy? given *request* and *cspNavigationType* is "`Blocked`", then set *response* to a network error and break. [CSP][p1411]

4. Set *response* to null.

5. If *fetchController* is null, then set *fetchController* to the result of fetching *request*, with *processEarlyHintsResponse* set to *processEarlyHintsResponse* as defined below, *processResponse* set to *processResponse* as defined below, and *useParallelQueue* set to true.

   Let *processEarlyHintsResponse* be the following algorithm given a response *earlyResponse*:

   1. If *commitEarlyHints* is null, then set *commitEarlyHints* to the result of processing early hint headers[p182] given *earlyResponse* and *request*'s reserved client.

   Let *processResponse* be the following algorithm given a response *fetchedResponse*:

   1. Set *response* to *fetchedResponse*.

6. Otherwise, process the next manual redirect for *fetchController*.

> **Note**
> *This will result in calling the processResponse we supplied above, during our first iteration through the loop, and thus setting response.*

> **Note**
> *Navigation handles redirects manually as navigation is the only place in the web platform that cares for redirects to `mailto:` URLs and such.*

7. Wait until either *response* is non-null, or *navigable*'s ongoing navigation[p989] changes to no longer equal *navigationId*.

   If the latter condition occurs, then abort *fetchController*, and return.

   Otherwise, proceed onward.

8. If *request*'s body is null, then set *entry*'s document state[p968]'s resource[p969] to null.

> **Note**
> *Fetch unsets the body for particular redirects.*

9. Set *responsePolicyContainer* to the result of creating a policy container from a fetch response[p888] given *response* and *request*'s reserved client.

10. Set *finalSandboxFlags* to the union of *targetSnapshotParams*'s sandboxing flags[p975] and *responsePolicyContainer*'s CSP list[p888]'s CSP-derived sandboxing flags[p887].

11. Set *responseOrigin* to the result of determining the origin[p964] given *response*'s URL, *finalSandboxFlags*, and *entry*'s document state[p968]'s initiator origin[p969].

12. If *navigable* is a top-level traversable[p953], then:

    1. Set *responseCOOP* to the result of obtaining a cross-origin opener policy[p875] given *response* and *request*'s reserved client.

    2. Set *coopEnforcementResult* to the result of enforcing the response's cross-origin opener policy[p876] given *navigable*'s active browsing context[p952], *response*'s URL, *responseOrigin*, *responseCOOP*, *coopEnforcementResult* and *request*'s referrer.

    3. If *finalSandboxFlags* is not empty and *responseCOOP*'s value[p874] is not "`unsafe-none`[p874]", then set *response* to an appropriate network error and break.

Note

This results in a network error as one cannot simultaneously provide a clean slate to a response using cross-origin opener policy and sandbox the result of navigating to that response.

13. If *response* is not a network error, *navigable* is a child navigable[p955], and the result of performing a cross-origin resource policy check with *navigable*'s container document[p955]'s origin, *navigable*'s container document[p955]'s relevant settings object[p1039], *request*'s destination, *response*, and true is **blocked**, then set *response* to a network error and break.

Note

Here we're running the cross-origin resource policy check against the parent navigable[p952] rather than navigable *itself. This is because we care about the same-originness of the embedded content against the parent context, not the navigation source.*

14. Set *locationURL* to *response*'s location URL given *currentURL*'s fragment.

15. If *locationURL* is failure or null, then break.

16. Assert: *locationURL* is a URL.

17. Set *entry*'s classic history API state[p968] to StructuredSerializeForStorage[p120](null).

18. Let *oldDocState* be *entry*'s document state[p968].

19. Set *entry*'s document state[p968] to a new document state[p969], with

history policy container[p969]
: a clone[p888] of the *oldDocState*'s history policy container[p969] if it is non-null; null otherwise

request referrer[p969]
: *oldDocState*'s request referrer[p969]

request referrer policy[p969]
: *oldDocState*'s request referrer policy[p969]

initiator origin[p969]
: *oldDocState*'s initiator origin[p969]

origin[p969]
: *oldDocState*'s origin[p969]

about base URL[p969]
: *oldDocState*'s about base URL[p969]

resource[p969]
: *oldDocState*'s resource[p969]

ever populated[p969]
: *oldDocState*'s ever populated[p969]

navigable target name[p970]
: *oldDocState*'s navigable target name[p970]

Note

For the navigation case, only entry *referenced* oldDocState*, which was created early in the navigate algorithm[p979]. So for navigations, this is functionally just an update to* entry's *document state[p968]. For the traversal case, it's possible adjacent session history entries[p968] also reference* oldDocState*, in which case they will continue doing so even after we've updated* entry's *document state[p968].*

Note

oldDocState's *history policy container[p969] is only ever non-null here in the traversal case, after we've populated it during a navigation to a URL that requires storing the policy container in history[p888].*

Example

The setup is given by the following Jake diagram[p956]:

	0	1	2	3
top	/a	/a#foo	/a#bar	/b

Also assume that the document state[p968] shared by the entries in steps 0, 1, and 2 has a null document[p969],

i.e., bfcache[p969] is not in play.

Now consider the scenario where we traverse back to step 2, but this time when fetching `/a`, the server responds with a `Location` header pointing to `/c`. That is, *locationURL* points to `/c` and so we have reached this step instead of breaking out of the loop.

In this case, we replace the document state[p968] of the session history entry[p968] occupying step 2, but we do *not* replace the document state of the entries occupying steps 0 and 1. The resulting Jake diagram[p956] looks like this:

	0	1	2	3
top	/a	/a#foo	***/c#bar***	/b

Note that we perform this replacement even if we end up in a redirect chain back to the original URL, for example if `/c` itself had a `Location` header pointing to `/a`. Such a case would end up like so:

	0	1	2	3
top	/a	/a#foo	***/a#bar***	/b

20. If *locationURL*'s scheme is not an HTTP(S) scheme, then:
    1. Set *entry*'s document state[p968]'s resource[p969] to null.
    2. Break.
21. Set *currentURL* to *locationURL*.
22. Set *entry*'s URL[p968] to *currentURL*.

Note

By the end of this loop we will be in one of these scenarios:

- locationURL *is failure, because of an unparseable* `Location` *header.*
- locationURL *is null, either because* response *is a network error or because we successfully fetched a non-network error HTTP(S) response with no* `Location` *header.*
- locationURL *is a URL with a non-HTTP(S) scheme.*

20. If *locationURL* is a URL whose scheme is not a fetch scheme, then return a new non-fetch scheme navigation params[p986], with

id[p986]
: *navigationId*

navigable[p986]
: *navigable*

URL[p986]
: *locationURL*

target snapshot sandboxing flags[p986]
: *targetSnapshotParams*'s sandboxing flags[p975]

source snapshot has transient activation[p986]
: *sourceSnapshotParams*'s has transient activation[p975]

initiator origin[p986]
: origin

navigation timing type[p986]
: *navTimingType*

Note

At this point, request's *current URL is the last URL in the redirect chain with a fetch scheme before redirecting to a non-fetch scheme URL. It is this URL's origin that will be used as the initiator origin for navigations to non-fetch scheme URLs.*

21. If any of the following are true:

    - *response* is a network error;
    - *locationURL* is failure; or
    - *locationURL* is a URL whose scheme is a fetch scheme

    then return null.

    Note

    We allow redirects to non-fetch scheme URLs, but redirects to fetch scheme URLs that aren't HTTP(S) are treated like network errors.

22. Assert: *locationURL* is null and *response* is not a network error.

23. Let *resultPolicyContainer* be the result of determining navigation params policy container[p888] given *response*'s URL, *entry*'s document state[p968]'s history policy container[p969], *sourceSnapshotParams*'s source policy container[p975], null, and *responsePolicyContainer*.

24. If *navigable*'s container[p955] is an `iframe`[p383], and *response*'s timing allow passed flag is set, then set container[p955]'s pending resource-timing start time[p387] to null.

    Note

    If the `iframe`[p383] is allowed to report to resource timing, we don't need to run its fallback steps as the normal reporting would happen.

25. Return a new navigation params[p975], with

    id[p975]
    navigationId
    navigable[p976]
    navigable
    request[p976]
    request
    response[p976]
    response
    fetch controller[p976]
    fetchController
    commit early hints[p976]
    commitEarlyHints
    cross-origin opener policy[p976]
    responseCOOP
    reserved environment[p976]
    request's reserved client
    origin[p976]
    responseOrigin
    policy container[p976]
    resultPolicyContainer
    final sandboxing flag set[p976]
    finalSandboxFlags
    COOP enforcement result[p976]
    coopEnforcementResult
    navigation timing type[p976]
    navTimingType
    about base URL[p976]
    entry's document state[p968]'s about base URL[p969]

An element has a **browsing context scope origin** if its `Document`[p127]'s node navigable[p953] is a top-level traversable[p953] or if all of its `Document`[p127]'s ancestor navigables[p957] all have active documents[p952] whose origins are the same origin[p870] as the element's node document's origin. If an element has a browsing context scope origin[p1000], then its value is the origin of the element's node document.

This definition is broken and needs investigation to see what it was intended to express: see issue #4703.

To **load a document** given navigation params[p975] *navigationParams*, source snapshot params[p975] *sourceSnapshotParams*, and origin[p869] *initiatorOrigin*, perform the following steps. They return a `Document`[p127] or null.

1. Let *type* be the computed type of *navigationParams*'s response[p976].

2. If the user agent has been configured to process resources of the given *type* using some mechanism other than rendering the content in a navigable[p952], then skip this step. Otherwise, if the *type* is one of the following types:

   ↪ **an HTML MIME type**

   Return the result of loading an HTML document[p1017], given *navigationParams*.

   ↪ **an XML MIME type that is not an explicitly supported XML MIME type**[p1001]

   Return the result of loading an XML document[p1017] given *navigationParams* and *type*.

   ↪ **a JavaScript MIME type**

   ↪ **a JSON MIME type that is not an explicitly supported JSON MIME type**[p1001]

   ↪ **"`text/css`[p1409]"**

   ↪ **"`text/plain`"**

   ↪ **"`text/vtt`[p1409]"**

   Return the result of loading a text document[p1018] given *navigationParams* and *type*.

   ↪ **"`multipart/x-mixed-replace`[p1381]"**

   Return the result of loading a `multipart/x-mixed-replace` document[p1018], given *navigationParams*, *sourceSnapshotParams*, and *initiatorOrigin*.

   ↪ **A supported image, video, or audio type**

   Return the result of loading a media document[p1019] given *navigationParams* and *type*.

   ↪ **"`application/pdf`"**

   ↪ **"`text/pdf`"**

   If the user agent's PDF viewer supported[p1117] is true, return the result of creating a document for inline content that doesn't have a DOM[p1019] given *navigationParams*'s navigable[p976].

   Otherwise, proceed onward.

   An **explicitly supported XML MIME type** is an XML MIME type for which the user agent is configured to use an external application to render the content, or for which the user agent has dedicated processing rules. For example, a web browser with a built-in Atom feed viewer would be said to explicitly support the `application/atom+xml`[p1408] MIME type.

   An **explicitly supported JSON MIME type** is a JSON MIME type for which the user agent is configured to use an external application to render the content, or for which the user agent has dedicated processing rules.

   Note

   In both cases, the external application or user agent will either display the content inline[p1019] directly in navigationParams's *navigable[p976], or hand it off to external software[p986]. Both happen in the steps below.*

3. If, given *type*, the new resource is to be handled by displaying some sort of inline content, e.g., a native rendering of the content or an error message because the specified type is not supported, then return the result of creating a document for inline content that doesn't have a DOM[p1019] given *navigationParams*'s navigable[p976], *navigationParams*'s id[p975], and *navigationParams*'s navigation timing type[p976].

4. Otherwise, the document's *type* is such that the resource will not affect *navigationParams*'s navigable[p976], e.g., because the resource is to be handed to an external application or because it is an unknown type that will be processed as a download[p305]. Hand-off to external software[p986] given *navigationParams*'s response[p976], *navigationParams*'s navigable[p976], *navigationParams*'s final sandboxing flag set[p976], *sourceSnapshotParams*'s has transient activation[p975], and *initiatorOrigin*.

5. Return null.

7.4.6 Applying the history step §[p1001]

For both navigation and traversal, once we have an idea of where we want to head to in the session history, much of the work comes about in applying that notion to the traversable navigable[p953] and the relevant `Document`[p127]. For navigations, this work generally occurs toward the end of the process; for traversals, it is the beginning.

7.4.6.1 Updating the traversable §[p1002]

Ensuring a traversable[p953] ends up at the right session history step is particularly complex, as it can involve coordinating across multiple navigable[p952] descendants of the traversable, populating[p992] them in parallel, and then synchronizing back up to ensure everyone has the same view of the result. This is further complicated by the existence of synchronous same-document navigations being mixed together with cross-document navigations, and how web pages have come to have certain relative timing expectations.

A **changing navigable continuation state** is used to store information during the apply the history step[p1002] algorithm, allowing parts of the algorithm to continue only after other parts have finished. It is a struct with:

displayed document

A `Document`[p127]

target entry

A session history entry[p968]

navigable

A navigable[p952]

update only

A boolean

Although all updates to the traversable navigable[p953] end up in the same apply the history step[p1002] algorithm, each possible entry point comes along with some minor customizations:

To **update for navigable creation/destruction** given a traversable navigable[p953] *traversable*:

1. Let *step* be *traversable*'s current session history step[p953].
2. Return the result of applying the history step[p1002] *step* to *traversable* given false, false, null, null, and null.

To **apply the push/replace history step** given a non-negative integer *step* to a traversable navigable[p953] *traversable*:

1. Return the result of applying the history step[p1002] *step* to *traversable* given false, false, null, null, and null.

Note

Apply the push/replace history step[p1002] never passes source snapshot params[p975] or an initiator navigable[p952] to apply the history step[p1002]. This is because those checks are done earlier in the navigation[p977] algorithm.

To **apply the reload history step** given a non-negative integer *step* to a traversable navigable[p953] *traversable*:

1. Let *step* be *traversable*'s current session history step[p953].
2. Return the result of applying the history step[p1002] *step* to *traversable* given true, false, null, null, and null.

Note

Apply the reload history step[p1002] never passes source snapshot params[p975] or an initiator navigable[p952] to apply the history step[p1002]. This is because reloading is always treated as if it were done by the navigable[p952] itself, even in cases like `parent.location.reload()`.

Now for the algorithm itself.

To **apply the traverse history step** given a non-negative integer *step* to a traversable navigable[p953] *traversable*, with source snapshot params[p975] *sourceSnapshotParams*, navigable[p952] *initiatorToCheck*, and user navigation involvement[p977] *userInvolvement*, perform the following steps. They return either "`initiator-disallowed`", "`canceled-by-beforeunload`", "`canceled-by-navigate`", or "`applied`".

1. Return the result of applying the history step[p1002] *step* to *traversable* given true, true, *sourceSnapshotParams*, *initiatorToCheck*, and *userInvolvement*.

To **apply the history step** given a non-negative integer *step* to a traversable navigable[p953] *traversable*, with booleans *checkForCancelation* and *fireNavigateEventOnCommit*, source snapshot params[p975]-or-null *sourceSnapshotParams*, navigable[p952]-or-

null *initiatorToCheck*, and user navigation involvement[p977]-or-null *userInvolvementForNavigateEvents*:

1. Assert: This is running within *traversable*'s session history traversal queue[p953].
2. Let *targetStep* be the result of getting the used step[p1007] given *traversable* and *step*.
3. If *initiatorToCheck* is not null, then:
    1. Assert: *sourceSnapshotParams* is not null.
    2. For each *navigable* of get all navigables whose current session history entry will change or reload[p1007]: if *initiatorToCheck* is not allowed by sandboxing to navigate[p987] *navigable* given *sourceSnapshotParams*, then return "`initiator-disallowed`".
4. Let *navigablesCrossingDocuments* be the result of getting all navigables that might experience a cross-document traversal[p1008] given *traversable* and *targetStep*.
5. If *checkForCancelation* is true, and the result of checking if unloading is canceled[p987] given *navigablesCrossingDocuments*, *traversable*, *targetStep*, and *userInvolvementForNavigateEvents* is not "`continue`", then return that result.
6. Let *changingNavigables* be the result of get all navigables whose current session history entry will change or reload[p1007] given *traversable* and *targetStep*.
7. Let *nonchangingNavigablesThatStillNeedUpdates* be the result of getting all navigables that only need history object length/index update[p1007] given *traversable* and *targetStep*.
8. For each *navigable* of *changingNavigables*:
    1. Let *targetEntry* be the result of getting the target history entry[p1008] given *navigable* and *targetStep*.
    2. Set *navigable*'s current session history entry[p952] to *targetEntry*.
    3. Set the ongoing navigation[p989] for *navigable* to "`traversal`".
9. Let *totalChangeJobs* be the size of *changingNavigables*.
10. Let *completedChangeJobs* be 0.
11. Let *changingNavigableContinuations* be an empty queue of changing navigable continuation states[p1002].

    Note
    This queue is used to split the operations on changingNavigables *into two parts. Specifically,* changingNavigableContinuations *holds data for the second part*[p1005].

12. For each *navigable* of *changingNavigables*, queue a global task[p1073] on the navigation and traversal task source[p1081] of *navigable*'s active window[p952] to run the steps:

    Note
    This set of steps are split into two parts to allow synchronous navigations to be processed before documents unload. State is stored in changingNavigableContinuations *for the second part*[p1005].

    1. Let *displayedEntry* be *navigable*'s active session history entry[p952].
    2. Let *targetEntry* be *navigable*'s current session history entry[p952].
    3. Let *changingNavigableContinuation* be a changing navigable continuation state[p1002] with:

       displayed document[p1002]
       displayedEntry's document[p968]
       target entry[p1002]
       targetEntry
       navigable[p1002]
       navigable
       update-only[p1002]
       false

    4. If *displayedEntry* is *targetEntry* and *targetEntry*'s document state[p968]'s reload pending[p969] is false, then:
        1. Set *changingNavigableContinuation*'s update-only[p1002] to true.

2. Enqueue *changingNavigableContinuation* on *changingNavigableContinuations*.

3. Abort these steps.

Note

This case occurs due to a synchronous navigation[p985] which already updated the active session history entry[p952].

5. Let *oldOrigin* be *targetEntry*'s document state[p968]'s origin[p969].

6. If *targetEntry*'s document[p968] is null, or *targetEntry*'s document state[p968]'s reload pending[p969] is true, then:

   1. Let *navTimingType* be "`back_forward`" if *targetEntry*'s document[p968] is null; otherwise "`reload`".

   2. Let *targetSnapshotParams* be the result of snapshotting target snapshot params[p975] given *navigable*.

   3. Let *potentiallyTargetSpecificSourceSnapshotParams* be *sourceSnapshotParams*.

   4. If *potentiallyTargetSpecificSourceSnapshotParams* is null, then set it to the result of snapshotting source snapshot params[p975] given *navigable*'s active document[p952].

      Note

      In this case there is no clear source of the traversal/reload. We treat this situation as if navigable *navigated itself, but note that some properties of* targetEntry'*s original initiator are preserved in* targetEntry'*s document state[p968], such as the initiator origin[p969] and referrer[p969], which will appropriately influence the navigation.*

   5. Set *targetEntry*'s document state[p968]'s reload pending[p969] to false.

   6. Let *allowPOST* be *targetEntry*'s document state[p968]'s reload pending[p969].

   7. In parallel[p43], attempt to populate the history entry's document[p992] for *targetEntry*, given *navigable*, *potentiallyTargetSpecificSourceSnapshotParams*, *targetSnapshotParams*, with *allowPOST[p992]* set to *allowPOST* and *completionSteps[p992]* set to queue a global task[p1073] on the navigation and traversal task source[p1081] given *navigable*'s active window[p952] to run *afterDocumentPopulated*.

Otherwise, run *afterDocumentPopulated* immediately[p43].

In both cases, let *afterDocumentPopulated* be the following steps:

1. If *targetEntry*'s document[p968] is null, then set *changingNavigableContinuation*'s update-only[p1002] to true.

   Note

   This means we tried to populate the document, but were unable to do so, e.g. because of the server returning a 204.

   Note

   These kinds of failed navigations or traversals will not be signaled to the navigation API[p919] (e.g., through the promises of any navigation API method tracker[p934], or the `navigateerror`[p1407] *event). Doing so would leak information about the timing of responses from other origins, in the cross-origin case, and providing different results in the cross-origin vs. same-origin cases was deemed too confusing.*

   However, implementations could use this opportunity to clear any promise handlers for the `navigation.transition.finished`[p939] *promise, as they are guaranteed at this point to never run. And, they might wish to report a warning to the console if any part of the navigation API initiated these navigations, to make it clear to the web developer why their promises will never settle and events will never fire.*

2. If *targetEntry*'s document[p968]'s origin is not *oldOrigin*, then set *targetEntry*'s classic history API state[p968] to StructuredSerializeForStorage[p120](null).

   Note

   This clears history state when the origin changed vs a previous load of targetEntry *without a redirect occuring. This can happen due to a change in CSP sandbox headers.*

3. If all of the following are true:

    - *navigable*'s parent[p952] is null;
    - *targetEntry*'s document[p968]'s browsing context[p961] is not an auxiliary browsing context[p961] whose opener browsing context[p961] is non-null; and
    - *targetEntry*'s document[p968]'s origin is not *oldOrigin*

    then set *targetEntry*'s document state[p968]'s navigable target name[p970] to the empty string.

4. Enqueue *changingNavigableContinuation* on *changingNavigableContinuations*.

    Note

    The rest of this job runs later[p1005] in this algorithm.

13. Let *navigablesThatMustWaitBeforeHandlingSyncNavigation* be an empty set.

14. While *completedChangeJobs* does not equal *totalChangeJobs*:

    1. If *traversable*'s running nested apply history step[p953] is false, then:

        1. While *traversable*'s session history traversal queue[p953]'s algorithm set[p970] contains one or more synchronous navigation steps[p970] with a target navigable[p970] not contained in *navigablesThatMustWaitBeforeHandlingSyncNavigation*:

            1. Let *steps* be the first item in *traversable*'s session history traversal queue[p953]'s algorithm set[p970] that is synchronous navigation steps[p970] with a target navigable[p970] not contained in *navigablesThatMustWaitBeforeHandlingSyncNavigation*.
            2. Remove *steps* from *traversable*'s session history traversal queue[p953]'s algorithm set[p970].
            3. Set *traversable*'s running nested apply history step[p953] to true.
            4. Run *steps*.
            5. Set *traversable*'s running nested apply history step[p953] to false.

        Note

        Synchronous navigations that are intended to take place before this traversal jump the queue at this point, so they can be added to the correct place in traversable's *session history entries[p953] before this traversal potentially unloads their document. More details can be found here[p971].*

    2. Let *changingNavigableContinuation* be the result of dequeuing from *changingNavigableContinuations*.
    3. If *changingNavigableContinuation* is nothing, then continue.
    4. Let *displayedDocument* be *changingNavigableContinuation*'s displayed document[p1002].
    5. Let *targetEntry* be *changingNavigableContinuation*'s target entry[p1002].
    6. Let *navigable* be *changingNavigableContinuation*'s navigable[p1002].
    7. Set the ongoing navigation[p989] for *navigable* to null.

        Note

        This allows new navigations[p977] of navigable *to start, whereas during the traversal they were blocked.*

    8. Let (*scriptHistoryLength*, *scriptHistoryIndex*) be the result of getting the history object length and index[p1007] given *traversable* and *targetStep*.

        Note

        These values might have changed since they were last calculated.

    9. Append *navigable* to *navigablesThatMustWaitBeforeHandlingSyncNavigation*.

Note

Once a navigable has reached this point in traversal, additionally queued synchronous navigation steps are likely to be intended to occur after this traversal rather than before it, so they no longer jump the queue. More details can be found here[p971].

10. Let *entriesForNavigationAPI* be the result of getting session history entries for the navigation API[p973] given *navigable* and *targetStep*.

11. Queue a global task[p1073] on the navigation and traversal task source[p1081] given *navigable*'s active window[p952] to run the steps:

    1. If *changingNavigableContinuation*'s update-only[p1002] is false, then:

        1. Unload[p1021] *displayedDocument* given *targetEntry*'s document[p968].

        2. For each *childNavigable* of *displayedDocument*'s descendant navigables[p957], queue a global task[p1073] on the navigation and traversal task source[p1081] given *childNavigable*'s active window[p952] to unload[p1021] *childNavigable*'s active document[p952].

        3. Activate history entry[p1006] *targetEntry* for *navigable*.

    2. If *navigable* is not *traversable*, and *targetEntry* is not *navigable*'s current session history entry[p952], and *targetEntry*'s document state[p968]'s origin[p969] is the same[p870] as *navigable*'s current session history entry[p952]'s document state[p968]'s origin[p969], then fire a traverse `navigate` event[p943] given *targetEntry* and *userInvolvementForNavigateEvents*.

    3. Let *updateDocument* be an algorithm step which performs update document for history step application[p1009] given *targetEntry*'s document[p968], *targetEntry*, *changingNavigableContinuation*'s update-only[p1002], *scriptHistoryLength*, *scriptHistoryIndex*, and *entriesForNavigationAPI*.

    4. If *targetEntry*'s document[p968] is equal to *displayedDocument*, then perform *updateDocument*.

    5. Otherwise, queue a global task[p1073] on the navigation and traversal task source[p1081] given *targetEntry*'s document[p968]'s relevant global object[p1039] to perform *updateDocument*.

    6. Increment *completedChangeJobs*.

15. Let *totalNonchangingJobs* be the size of *nonchangingNavigablesThatStillNeedUpdates*.

Note

This step onwards deliberately waits for all the previous operations to complete, as they include processing synchronous navigations[p1005] which will also post tasks to update history length and index.

16. Let *completedNonchangingJobs* be 0.

17. Let (*scriptHistoryLength*, *scriptHistoryIndex*) be the result of getting the history object length and index[p1007] given *traversable* and *targetStep*.

18. For each *navigable* of *nonchangingNavigablesThatStillNeedUpdates*, queue a global task[p1073] on the navigation and traversal task source[p1081] given *navigable*'s active window[p952] to run the steps:

    1. Let *document* be *navigable*'s active document[p952].

    2. Set *document*'s history object[p916]'s index[p916] to *scriptHistoryIndex*.

    3. Set *document*'s history object[p916]'s length[p916] to *scriptHistoryLength*.

    4. Increment *completedNonchangingJobs*.

19. Wait for *completedNonchangingJobs* to equal *totalNonchangingJobs*.

20. Set *traversable*'s current session history step[p953] to *targetStep*.

21. Return "`applied`".

To **activate history entry** session history entry[p968] *entry* for navigable[p952] *navigable*:

1. Save persisted state[p1012] to the navigable[p952]'s active session history entry[p952].

2. Let *newDocument* be *entry*'s document[p968].

3. Assert: *newDocument*'s is initial `about:blank`[p128] is false, i.e., we never traverse back to the initial `about:blank`[p128] `Document`[p127] because it always gets replaced[p978] when we navigate away from it.

4. Set *navigable*'s active session history entry[p952] to *entry*.

5. Make active[p1010] *newDocument*.

To **get the used step** given a traversable navigable[p953] *traversable*, and a non-negative integer *step*, perform the following steps. They return a non-negative integer.

1. Let *steps* be the result of getting all used history steps[p974] within *traversable*.

2. Return the greatest item in *steps* that is less than or equal to *step*.

> **Note**
> *This caters for situations where there's no session history entry[p968] with step[p968]* step*, due to the removal of a navigable[p952].*

To **get the history object length and index** given a traversable navigable[p953] *traversable*, and a non-negative integer *step*, perform the following steps. They return a tuple of two non-negative integers.

1. Let *steps* be the result of getting all used history steps[p974] within *traversable*.

2. Let *scriptHistoryLength* be the size of *steps*.

3. Assert: *steps* contains *step*.

> **Note**
> *It is assumed that* step *has been adjusted by getting the used step[p1007].*

4. Let *scriptHistoryIndex* be the index of *step* in *steps*.

5. Return (*scriptHistoryLength*, *scriptHistoryIndex*).

To **get all navigables whose current session history entry will change or reload** given a traversable navigable[p953] *traversable*, and a non-negative integer *targetStep*, perform the following steps. They return a list of navigables[p952].

1. Let *results* be an empty list.

2. Let *navigablesToCheck* be « *traversable* ».

> **Note**
> *This list is extended in the loop below.*

3. For each *navigable* of *navigablesToCheck*:

    1. Let *targetEntry* be the result of getting the target history entry[p1008] given *navigable* and *targetStep*.

    2. If *targetEntry* is not *navigable*'s current session history entry[p952] or *targetEntry*'s document state[p968]'s reload pending[p969] is true, then append *navigable* to *results*.

    3. If *targetEntry*'s document[p968] is *navigable*'s document[p952], and *targetEntry*'s document state[p968]'s reload pending[p969] is false, then extend *navigablesToCheck* with the child navigables[p955] of *navigable*.

    > **Note**
    > *Adding child navigables[p955] to* navigablesToCheck *means those navigables will also be checked by this loop. Child navigables[p955] are only checked if the* navigable's *active document[p952] will not change as part of this traversal.*

4. Return *results*.

To **get all navigables that only need history object length/index update** given a traversable navigable[p953] *traversable*, and a non-negative integer *targetStep*, perform the following steps. They return a list of navigables[p952].

Note

Other navigables[p952] might not be impacted by the traversal. For example, if the response is a 204, the currently active document will remain. Additionally, going 'back' after a 204 will change the current session history entry[p952], but the active session history entry[p952] will already be correct.

1. Let *results* be an empty list.
2. Let *navigablesToCheck* be « *traversable* ».

   Note

   This list is extended in the loop below.

3. For each *navigable* of *navigablesToCheck*:
   1. Let *targetEntry* be the result of getting the target history entry[p1008] given *navigable* and *targetStep*.
   2. If *targetEntry* is *navigable*'s current session history entry[p952] and *targetEntry*'s document state[p968]'s reload pending[p969] is false, then:
      1. Append *navigable* to *results*.
      2. Extend *navigablesToCheck* with *navigable*'s child navigables[p955].

         Note

         Adding child navigables[p955] to navigablesToCheck *means those navigables will also be checked by this loop. child navigables[p955] are only checked if the* navigable's *active document[p952] will not change as part of this traversal.*

4. Return *results*.

To **get the target history entry** given a navigable[p952] *navigable*, and a non-negative integer *step*, perform the following steps. They return a session history entry[p968].

1. Let *entries* be the result of getting session history entries[p973] for *navigable*.
2. Return the item in *entries* that has the greatest step[p968] less than or equal to *step*.

Example

To see why getting the target history entry[p1008] returns the entry with the greatest step[p968] less than or equal to the input step, consider the following Jake diagram[p956]:

	0	1	2	3
top	/t			/t#foo
frames[0]	/i-0-a	/i-0-b		

For the input step 1, the target history entry for the `top` navigable is the `/t` entry, whose step[p968] is 0, while the target history entry for the `frames[0]` navigable is the `/i-0-b` entry, whose step[p968] is 1:

	0	1	2	3
top	***/t***			/t#foo
frames[0]	/i-0-a	***/i-0-b***		

Similarly, given the input step 3 we get the `top` entry whose step[p968] is 3, and the `frames[0]` entry whose step[p968] is 1:

	0	1	2	3
top	/t			***/t#foo***
frames[0]	/i-0-a	***/i-0-b***		

To **get all navigables that might experience a cross-document traversal** given a traversable navigable[p953] *traversable*, and a non-negative integer *targetStep*, perform the following steps. They return a list of navigables[p952].

Note

From traversable's *session history traversal queue*[p953]*'s perspective, these documents are candidates for going cross-document during the traversal described by* targetStep*. They will not experience a cross-document traversal if the status code for their target document is HTTP 204 No Content.*

Note that if a given navigable[p952] *might experience a cross-document traversal, this algorithm will return navigable*[p952] *but not its child navigables*[p955]*. Those would end up unloaded*[p1021]*, not traversed.*

1. Let *results* be an empty list.
2. Let *navigablesToCheck* be « *traversable* ».

   Note

   This list is extended in the loop below.

3. For each *navigable* of *navigablesToCheck*:
   1. Let *targetEntry* be the result of getting the target history entry[p1008] given *navigable* and *targetStep*.
   2. If *targetEntry*'s document[p968] is not *navigable*'s document[p952] or *targetEntry*'s document state[p968]'s reload pending[p969] is true, then append *navigable* to *results*.

      Note

      Although navigable's *active history entry*[p952] *can change synchronously, the new entry will always have the same* `Document`[p127]*, so accessing* navigable's *document*[p952] *is reliable.*

   3. Otherwise, extend *navigablesToCheck* with *navigable*'s child navigables[p955].

      Note

      Adding child navigables[p955] *to* navigablesToCheck *means those navigables will also be checked by this loop. Child navigables*[p955] *are only checked if the* navigable's *active document*[p952] *will not change as part of this traversal.*

4. Return *results*.

7.4.6.2 Updating the document §[p1009]

To **update document for history step application** given a `Document`[p127] *document*, a session history entry[p968] *entry*, a boolean *doNotReactivate*, integers *scriptHistoryLength* and *scriptHistoryIndex*, and an optional list of session history entries[p968] *entriesForNavigationAPI*:

1. Let *documentIsNew* be true if *document*'s latest entry[p970] is null; otherwise false.
2. Let *documentsEntryChanged* be true if *document*'s latest entry[p970] is not *entry*; otherwise false.
3. Set *document*'s history object[p916]'s index[p916] to *scriptHistoryIndex*.
4. Set *document*'s history object[p916]'s length[p916] to *scriptHistoryLength*.
5. If *documentsEntryChanged* is true, then:
   1. Let *oldURL* be *document*'s latest entry[p970]'s URL[p968].
   2. Set *document*'s latest entry[p970] to *entry*.
   3. Restore the history object state[p1010] given *document* and *entry*.
   4. Let *navigation* be *history*'s relevant global object[p1039]'s navigation API[p922].
   5. If *documentIsNew* is false, then:
      1. Update the navigation API entries for a same-document navigation[p925] given *navigation*, *entry*, and "`traverse`[p924]".

2. Fire an event named popstate[p1407] at *document*'s relevant global object[p1039], using PopStateEvent[p949], with the state[p950] attribute initialized to *document*'s history object[p916]'s state[p916].

3. Restore persisted state[p1012] given *entry*.

4. If *oldURL*'s fragment is not equal to *entry*'s URL[p968]'s fragment, then queue a global task[p1073] on the DOM manipulation task source[p1080] given *document*'s relevant global object[p1039] to fire an event named hashchange[p1406] at *document*'s relevant global object[p1039], using HashChangeEvent[p950], with the oldURL[p950] attribute initialized to the serialization of *oldURL* and the newURL[p950] attribute initialized to the serialization of *entry*'s URL[p968].

6. Otherwise:

    1. Assert: *entriesForNavigationAPI* is given.

    2. Restore persisted state[p1012] given *entry*.

    3. Initialize the navigation API entries for a new document[p924] given *navigation*, *entriesForNavigationAPI*, and *entry*.

6. If *documentIsNew* is true, then:

    1. Try to scroll to the fragment[p1011] for *document*.

    2. At this point **scripts may run for the newly-created document** *document*.

7. Otherwise, if *documentsEntryChanged* is false and *doNotReactivate* is false, then:

    1. Assert: *entriesForNavigationAPI* is given.

    2. Reactivate[p1010] *document* given *entry* and *entriesForNavigationAPI*.

Note

documentsEntryChanged *can be false for one of two reasons: either we are restoring from bfcache[p969], or we are asynchronously finishing up a synchronous navigation which already synchronously set* document's *latest entry[p970]. The* doNotReactivate *argument distinguishes between these two cases.*

To **restore the history object state** given Document[p127] *document* and session history entry[p968] *entry*:

1. Let *targetRealm* be *document*'s relevant realm[p1039].

2. Let *state* be StructuredDeserialize[p120](*entry*'s classic history API state[p968], *targetRealm*). If this throws an exception, catch it and let *state* be null.

3. Set *document*'s history object[p916]'s state[p916] to *state*.

To **make active** a Document[p127] *document*:

1. Let *window* be *document*'s relevant global object[p1039].

2. Set *document*'s browsing context[p961]'s WindowProxy[p904]'s [[Window]][p904] internal slot value to *window*.

3. Set *document*'s visibility state[p807] to *document*'s node navigable[p953]'s traversable navigable[p953]'s system visibility state[p953].

4. Queue a new VisibilityStateEntry[p808] whose visibility state[p808] is *document*'s visibility state[p807] and whose timestamp[p808] is zero.

5. Set *window*'s relevant settings object[p1039]'s execution ready flag[p1032].

To **reactivate** a Document[p127] *document* given a session history entry[p968] *reactivatedEntry* and a list of session history entries[p968] *entriesForNavigationAPI*:

Note

This algorithm updates document *after it has come out of bfcache[p969], i.e., after it has been made fully active[p966] again. Other specifications that want to watch for this change to the fully active[p966] state are encouraged to add steps into this algorithm, so that the ordering of events that happen in effect of the change is clear.*

1. For each *formControl* of form controls in *document* with an autofill field name[p600] of "`off`[p596]", invoke the reset algorithm[p626] for *formControl*.
2. If *document*'s suspended timer handles[p1021] is not empty:
    1. Assert: *document*'s suspension time[p1021] is not zero.
    2. Let *suspendDuration* be the current high resolution time minus *document*'s suspension time[p1021].
    3. Let *activeTimers* be *document*'s relevant global object[p1039]'s map of active timers[p1101].
    4. For each *handle* in *document*'s suspended timer handles[p1021], if *activeTimers*[*handle*] exists, then increase *activeTimers*[*handle*] by *suspendDuration*.
3. Update the navigation API entries for reactivation[p924] given *document*'s relevant global object[p1039]'s navigation API[p922], *entriesForNavigationAPI*, and *reactivatedEntry*.
4. If *document*'s current document readiness[p130] is "`complete`", and *document*'s page showing[p1021] flag is false, then:
    1. Set *document*'s page showing[p1021] flag to true.
    2. Update the visibility state[p807] of *document* to "`visible`".
    3. Fire a page transition event[p951] named `pageshow`[p1407] at *document*'s relevant global object[p1039] with true.

To **try to scroll to the fragment** for a `Document`[p127] *document*, perform the following steps in parallel[p43]:

1. Wait for an implementation-defined amount of time. (This is intended to allow the user agent to optimize the user experience in the face of performance concerns.)
2. Queue a global task[p1073] on the navigation and traversal task source[p1081] given *document*'s relevant global object[p1039] to run these steps:
    1. If *document* has no parser, or its parser has stopped parsing[p1296], or the user agent has reason to believe the user is no longer interested in scrolling to the fragment, then abort these steps.
    2. Scroll to the fragment[p1011] given *document*.
    3. If *document*'s indicated part[p1012] is still null, then try to scroll to the fragment[p1011] for *document*.

7.4.6.3 Scrolling to a fragment §[p1011]

To **scroll to the fragment** given a `Document`[p127] *document*:

1. If *document*'s indicated part[p1012] is null, then set *document*'s target element[p1012] to null.
2. Otherwise, if *document*'s indicated part[p1012] is top of the document[p1012], then:
    1. Set *document*'s target element[p1012] to null.
    2. Scroll to the beginning of the document for *document*. [CSSOMVIEW][p1412]
    3. Return.
3. Otherwise:
    1. Assert: *document*'s indicated part[p1012] is an element.
    2. Let *target* be *document*'s indicated part[p1012].
    3. Set *document*'s target element[p1012] to *target*.
    4. Run the ancestor details revealing algorithm[p628] on *target*.
    5. Run the ancestor hidden-until-found revealing algorithm[p807] on *target*.
    6. Scroll *target* into view, with *behavior* set to "auto", *block* set to "start", and *inline* set to "nearest". [CSSOMVIEW][p1412]

7. Run the focusing steps[p822] for *target*, with the Document[p127]'s viewport as the *fallback target*.

8. Move the sequential focus navigation starting point[p825] to *target*.

A Document[p127]'s **indicated part** is the one that its URL's fragment identifies, or null if the fragment does not identify anything. The semantics of the fragment in terms of mapping it to a node is defined by the specification that defines the MIME type used by the Document[p127] (for example, the processing of fragments for XML MIME types is the responsibility of RFC7303). [RFC7303][p1416]

There is also a **target element** for each Document[p127], which is used in defining the `:target`[p766] pseudo-class and is updated by the above algorithm. It is initially null.

For an HTML document *document*, the following processing model must be followed to determine its indicated part[p1012]:

1. Let *fragment* be *document*'s URL's fragment.

2. If *fragment* is the empty string, then return the special value **top of the document**.

3. Let *potentialIndicatedElement* be the result of finding a potential indicated element[p1012] given *document* and *fragment*.

4. If *potentialIndicatedElement* is not null, then return *potentialIndicatedElement*.

5. Let *fragmentBytes* be the result of percent-decoding *fragment*.

6. Let *decodedFragment* be the result of running UTF-8 decode without BOM on *fragmentBytes*.

7. Set *potentialIndicatedElement* to the result of finding a potential indicated element[p1012] given *document* and *decodedFragment*.

8. If *potentialIndicatedElement* is not null, then return *potentialIndicatedElement*.

9. If *decodedFragment* is an ASCII case-insensitive match for the string `top`, then return the top of the document[p1012].

10. Return null.

To **find a potential indicated element** given a Document[p127] *document* and a string *fragment*, run these steps:

1. If there is an element in the document tree whose root is *document* and that has an ID equal to *fragment*, then return the first such element in tree order.

2. If there is an `a`[p252] element in the document tree whose root is *document* that has a `name`[p1363] attribute whose value is equal to *fragment*, then return the first such element in tree order.

3. Return null.

7.4.6.4 Persisted history entry state §[p1012]

To **save persisted state** to a session history entry[p968] *entry*:

1. Set the scroll position data[p968] of *entry* to contain the scroll positions for all of *entry*'s document[p968]'s restorable scrollable regions[p1013].

2. Optionally, update *entry*'s persisted user state[p968] to reflect any state that the user agent wishes to persist, such as the values of form fields.

To **restore persisted state** from a session history entry[p968] *entry*:

1. If *entry*'s scroll restoration mode[p968] is "`auto`[p969]", and *entry*'s document[p968]'s relevant global object[p1039]'s navigation API[p922]'s suppress normal scroll restoration during ongoing navigation[p934] is false, then restore scroll position data[p1013] given *entry*.

> **Note**
> *The user agent not restoring scroll positions does not imply that scroll positions will be left at any particular value (e.g., (0,0)). The actual scroll position depends on the navigation type and the user agent's particular caching strategy. So web applications cannot assume any particular scroll position but rather are urged to set it to what they want it to be.*

Note

If suppress normal scroll restoration during ongoing navigation[p934] is true, then restoring scroll position data[p1013] might still happen at a later point, as part of finishing[p948] the relevant NavigateEvent[p939], or via a navigateEvent.scroll()[p941] method call.

2. Optionally, update other aspects of *entry*'s document[p968] and its rendering, for instance values of form fields, that the user agent had previously recorded in *entry*'s persisted user state[p968].

Note

This can even include updating the dir[p156] attribute of textarea[p570] elements or input[p512] elements whose type[p514] attribute is in either the Text[p519] state or the Search[p519] state, if the persisted state includes the directionality of user input in such controls.

Note

Restoring the value of form controls as part of this process does not fire any input or change[p1406] events, but can trigger the formStateRestoreCallback of form-associated custom elements[p743].

Each Document[p127] has a boolean **has been scrolled by the user**, initially false. If the user scrolls the document, the user agent must set that document's has been scrolled by the user[p1013] to true.

The **restorable scrollable regions** of a Document[p127] *document* are *document*'s viewport, and all of *document*'s scrollable regions excepting any navigable containers[p955].

Note

Child navigable[p955] scroll restoration is handled as part of state restoration for the session history entry[p968] for those navigables[p952]' Document[p127]s.

To **restore scroll position data** given a session history entry[p968] *entry*:

1. Let *document* be *entry*'s document[p968].
2. If *document*'s has been scrolled by the user[p1013] is true, then the user agent should return.
3. The user agent should attempt to use *entry*'s scroll position data[p968] to restore the scroll positions of *entry*'s document[p968]'s restorable scrollable regions[p1013]. The user agent may continue to attempt to do so periodically, until *document*'s has been scrolled by the user[p1013] becomes true.

Note

This is formulated as an attempt*, which is potentially repeated until success or until the user scrolls, due to the fact that relevant content indicated by the scroll position data[p968] might take some time to load from the network.*

Note

Scroll restoration might be affected by scroll anchoring. [CSSSCROLLANCHORING][p1412]

7.5 Document lifecycle §[p10] 13

7.5.1 Shared document creation infrastructure §[p10] 13

When loading a document using one of the below algorithms, we use the following steps to **create and initialize a Document object**, given a type *type*, content type *contentType*, and navigation params[p975] *navigationParams*:

Note

Document[p127] objects are also created when creating a new browsing context and document[p962]; such initial about:blank[p128] Document[p127] are never created by this algorithm. Also, browsing context[p961]-less Document[p127] objects can be created via various APIs, such as document.implementation.createHTMLDocument().

1. Let *browsingContext* be *navigationParams*'s navigable[p976]'s active browsing context[p952].

2. Set *browsingContext* to the result of the obtaining a browsing context to use for a navigation response[p877] given *browsingContext*, *navigationParams*'s final sandboxing flag set[p976], *navigationParams*'s cross-origin opener policy[p976], and *navigationParams*'s COOP enforcement result[p976].

   Note

   This can result in a browsing context group switch[p876], in which case browsingContext *will be a newly-created[p962] browsing context[p961] instead of being* navigationParams's *navigable[p976]'s active browsing context[p952]. In such a case, the created* `Window`[p892], `Document`[p127], *and agent will not end up being used; because the created* `Document`[p127]'s *origin is opaque[p869], we will end up creating a new agent and* `Window`[p892] *later in this algorithm[p1014] to go along with the new* `Document`[p127].

3. Let *permissionsPolicy* be the result of creating a permissions policy from a response given *navigationParams*'s navigable[p976]'s container[p955], *navigationParams*'s origin[p976], and *navigationParams*'s response[p976]. [PERMISSIONSPOLICY][p1415]

   Note

   The creating a permissions policy from a response algorithm makes use of the passed origin[p869]. If `document.domain`[p872] *has been used for* navigationParams's *navigable[p976]'s container document[p955], then its origin cannot be same origin-domain[p870] with the passed origin, because these steps run before the* document *is created, so it cannot itself yet have used* `document.domain`[p872]*. Note that this means that Permissions Policy checks are less permissive compared to doing a same origin[p870] check instead.*

   See below for some examples of this in action.

4. Let *creationURL* be *navigationParams*'s response[p976]'s URL.

5. If *navigationParams*'s request[p976] is non-null, then set *creationURL* to *navigationParams*'s request[p976]'s current URL.

6. Let *window* be null.

7. If *browsingContext*'s active document[p961]'s is initial `about:blank`[p128] is true, and *browsingContext*'s active document[p961]'s origin is same origin-domain[p870] with *navigationParams*'s origin[p976], then set *window* to *browsingContext*'s active window[p961].

   Note

   This means that both the initial `about:blank`[p128] `Document`[p127]*, and the new* `Document`[p127] *that is about to be created, will share the same* `Window`[p892] *object.*

8. Otherwise:

   1. Let *oacHeader* be the result of getting a structured field value given `` `Origin-Agent-Cluster`[p873] `` and "`item`" from *navigationParams*'s response[p976]'s header list.

   2. Let *requestsOAC* be true if *oacHeader* is not null and *oacHeader*[0] is the boolean true; otherwise false.

   3. If *navigationParams*'s reserved environment[p976] is a non-secure context[p1039], then set *requestsOAC* to false.

   4. Let *agent* be the result of obtaining a similar-origin window agent[p1029] given *navigationParams*'s origin[p976], *browsingContext*'s group[p965], and *requestsOAC*.

   5. Let *realmExecutionContext* be the result of creating a new realm[p1033] given *agent* and the following customizations:

      - For the global object, create a new `Window`[p892] object.

      - For the global **this** binding, use *browsingContext*'s `WindowProxy`[p904] object.

   6. Set *window* to the global object[p1033] of *realmExecutionContext*'s Realm component.

   7. Let *topLevelCreationURL* be *creationURL*.

   8. Let *topLevelOrigin* be *navigationParams*'s origin[p976].

   9. If *navigable*'s container[p955] is not null, then:

      1. Let *parentEnvironment* be *navigable*'s container[p955]'s relevant settings object[p1039].

      2. Set *topLevelCreationURL* to *parentEnvironment*'s top-level creation URL[p1031].

3. Set *topLevelOrigin* to *parentEnvironment*'s top-level origin[p1031].

10. Set up a window environment settings object[p903] with *creationURL*, *realmExecutionContext*, *navigationParams*'s reserved environment[p976], *topLevelCreationURL*, and *topLevelOrigin*.

Note

This is the usual case, where the new `Document`[p127] *we're about to create gets a new* `Window`[p892] *to go along with it.*

9. Let *loadTimingInfo* be a new document load timing info[p131] with its navigation start time[p131] set to *navigationParams*'s response[p976]'s timing info's start time.

10. Let *document* be a new `Document`[p127], with

type
type
content type
contentType
origin
navigationParams's origin[p976]
browsing context[p961]
browsingContext
policy container[p128]
navigationParams's policy container[p976]
permissions policy[p128]
permissionsPolicy
active sandboxing flag set[p887]
navigationParams's final sandboxing flag set[p976]
cross-origin opener policy[p128]
navigationParams's cross-origin opener policy[p976]
load timing info[p131]
loadTimingInfo
was created via cross-origin redirects[p131]
navigationParams's response[p976]'s has cross-origin redirects
navigation id[p128]
navigationParams's id[p975]
URL
creationURL
current document readiness[p130]
`"loading"`
about base URL[p128]
navigationParams's about base URL[p976]

11. Set *window*'s associated `Document`[p894] to *document*.

12. Run CSP initialization for a `Document` given *document*. [CSP][p1411]

13. If *navigationParams*'s request[p976] is non-null, then:

    1. Set *document*'s referrer[p127] to the empty string.

    2. Let *referrer* be *navigationParams*'s request[p976]'s referrer.

    3. If *referrer* is a URL record, then set *document*'s referrer[p127] to the serialization of *referrer*.

    Note

    Per Fetch, referrer *will be either a URL record or* `"no-referrer"` *at this point.*

14. If *navigationParams*'s fetch controller[p976] is not null, then:

    1. Let *fullTimingInfo* be the result of extracting the full timing info from *navigationParams*'s fetch controller[p976].

    2. Let *redirectCount* be 0 if *navigationParams*'s response[p976]'s has cross-origin redirects is true; otherwise *navigationParams*'s request[p976]'s redirect count.

    3. Create the navigation timing entry for *document*, given *fullTimingInfo*, *redirectCount*, *navigationTimingType*, *navigationParams*'s response[p976]'s service worker timing info, and *navigationParams*'s response[p976]'s body info.

15. Create the navigation timing entry for *document*, with *navigationParams*'s response[p976]'s timing info, *redirectCount*, *navigationParams*'s navigation timing type[p976], and *navigationParams*'s response[p976]'s service worker timing info.

16. If *navigationParams*'s response[p976] has a `Refresh[p1025]` header, then:

    1. Let *value* be the isomorphic decoding of the value of the header.

    2. Run the shared declarative refresh steps[p191] with *document* and *value*.

    We do not currently have a spec for how to handle multiple `Refresh[p1025]` headers. This is tracked as issue #2900.

17. If *navigationParams*'s commit early hints[p976] is not null, then call *navigationParams*'s commit early hints[p976] with *document*.

18. Process link headers[p181] given *document*, *navigationParams*'s response[p976], and "`pre-media`".

19. Return *document*.

Example

In this example, the child document is not allowed to use `PaymentRequest`, despite being same origin-domain[p870] at the time the child document tries to use it. At the time the child document is initialized, only the parent document has set `document.domain`[p872], and the child document has not.

```
<!-- https://foo.example.com/a.html -->
<!doctype html>
<script>
document.domain = 'example.com';
</script>
<iframe src=b.html></iframe>
```

```
<!-- https://bar.example.com/b.html -->
<!doctype html>
<script>
document.domain = 'example.com'; // This happens after the document is initialized
new PaymentRequest(…); // Not allowed to use
</script>
```

Example

In this example, the child document *is* allowed to use `PaymentRequest`, despite not being same origin-domain[p870] at the time the child document tries to use it. At the time the child document is initialized, none of the documents have set `document.domain`[p872] yet so same origin-domain[p870] falls back to a normal same origin[p870] check.

```
<!-- https://example.com/a.html -->
<!doctype html>
<iframe src=b.html></iframe>
<!-- The child document is now initialized, before the script below is run. -->
<script>
document.domain = 'example.com';
</script>
```

```
<!-- https://example.com/b.html -->
<!doctype html>
<script>
new PaymentRequest(…); // Allowed to use
</script>
```

To **populate with `html`/`head`/`body`** given a `Document`[p127] *document*:

1. Let *html* be the result of creating an element given *document*, `html`[p167], and the HTML namespace.

2. Let *head* be the result of creating an element given *document*, `head`[p168], and the HTML namespace.

3. Let *body* be the result of creating an element given *document*, `body`[p199], and the HTML namespace.

4. Append *html* to *document*.
5. Append *head* to *html*.
6. Append *body* to *html*.

7.5.2 Loading HTML documents §[p1017]

To **load an HTML document**, given navigation params[p975] *navigationParams*:

1. Let *document* be the result of creating and initializing a `Document` object[p1013] given "`html`", "`text/html`", and *navigationParams*.
2. If *document*'s URL is `about:blank`[p53], then populate with `html`/`head`/`body`[p1016] given *document*.

   Note

   This special case, where even non-initial `about:blank`[p128] `Document`[p127]s are synchronously given their element nodes, is necessary for compatible with deployed content. In other words, it is not compatible to instead go down the "otherwise" branch and feed the empty byte sequence into an HTML parser[p1210] to asynchronously populate document.

3. Otherwise, create an HTML parser[p1210] and associate it with the *document*. Each task[p1071] that the networking task source[p1081] places on the task queue[p1071] while fetching runs must then fill the parser's input byte stream[p1216] with the fetched bytes and cause the HTML parser[p1210] to perform the appropriate processing of the input stream.

   The first task[p1071] that the networking task source[p1081] places on the task queue[p1071] while fetching runs must process link headers[p181] given *document*, *navigationParams*'s response[p976], and "`media`", after the task has been processed by the HTML parser[p1210].

   Before any script execution occurs, the user agent must wait for scripts may run for the newly-created document[p1010] to be true for *document*.

   Note

   The input byte stream[p1216] converts bytes into characters for use in the tokenizer[p1229]. This process relies, in part, on character encoding information found in the real Content-Type metadata[p96] of the resource; the computed type is not used for this purpose.

   When no more bytes are available, the user agent must queue a global task[p1073] on the networking task source[p1081] given *document*'s relevant global object[p1039] to have the parser to process the implied EOF character, which eventually causes a `load`[p1407] event to be fired.

4. Return *document*.

7.5.3 Loading XML documents §[p1017]

When faced with displaying an XML file inline, provided navigation params[p975] *navigationParams* and a string *type*, user agents must follow the requirements defined in *XML* and *Namespaces in XML*, *XML Media Types*, *DOM*, and other relevant specifications to create and initialize a `Document` object[p1013] *document*, given "`xml`", *type*, and *navigationParams*, and return that `Document`[p127]. They must also create a corresponding XML parser[p1321]. [XML][p1419] [XMLNS][p1419] [RFC7303][p1416] [DOM][p1412]

Note

At the time of writing, the XML specification community had not actually yet specified how XML and the DOM interact.

The first task[p1071] that the networking task source[p1081] places on the task queue[p1071] while fetching runs must process link headers[p181] given *document*, *navigationParams*'s response[p976], and "`media`", after the task has been processed by the XML parser[p1321].

The actual HTTP headers and other metadata, not the headers as mutated or implied by the algorithms given in this specification, are the ones that must be used when determining the character encoding according to the rules given in the above specifications. Once the character encoding is established, the document's character encoding must be set to that character encoding.

Before any script execution occurs, the user agent must wait for scripts may run for the newly-created document[p1010] to be true for the newly-created Document[p127].

Once parsing is complete, the user agent must set *document*'s navigation id[p128] to null.

Note

For HTML documents this is reset when parsing is complete, after firing the load event.

Error messages from the parse process (e.g., XML namespace well-formedness errors) may be reported inline by mutating the Document[p127].

7.5.4 Loading text documents §[p10 18]

To **load a text document**, given a navigation params[p975] *navigationParams* and a string *type*:

1. Let *document* be the result of creating and initializing a Document object[p1013] given "`html`", *type*, and *navigationParams*.
2. Set *document*'s parser cannot change the mode flag[p1263] to true.
3. Set *document*'s mode to "`no-quirks`".
4. Create an HTML parser[p1210] and associate it with the *document*. Act as if the tokenizer had emitted a start tag token with the tag name "pre" followed by a single U+000A LINE FEED (LF) character, and switch the HTML parser[p1210]'s tokenizer to the PLAINTEXT state[p1231]. Each task[p1071] that the networking task source[p1081] places on the task queue[p1071] while fetching runs must then fill the parser's input byte stream[p1216] with the fetched bytes and cause the HTML parser[p1210] to perform the appropriate processing of the input stream.

   document's encoding must be set to the character encoding used to decode the document during parsing.

   The first task[p1071] that the networking task source[p1081] places on the task queue[p1071] while fetching runs must process link headers[p181] given *document*, *navigationParams*'s response[p976], and "`media`", after the task has been processed by the HTML parser[p1210].

   Before any script execution occurs, the user agent must wait for scripts may run for the newly-created document[p1010] to be true for *document*.

   When no more bytes are available, the user agent must queue a global task[p1073] on the networking task source[p1081] given *document*'s relevant global object[p1039] to have the parser to process the implied EOF character, which eventually causes a load[p1407] event to be fired.
5. User agents may add content to the head[p168] element of *document*, e.g., linking to a style sheet, providing script, or giving the document a title[p169].

   Note

   In particular, if the user agent supports the `Format=Flowed` feature of RFC 3676 then the user agent would need to apply extra styling to cause the text to wrap correctly and to handle the quoting feature. This could be performed using, e.g., a CSS extension.
6. Return *document*.

The rules for how to convert the bytes of the plain text document into actual characters, and the rules for actually rendering the text to the user, are defined by the specifications for the computed MIME type of the resource (i.e., *type*).

7.5.5 Loading `multipart/x-mixed-replace`[p1381] documents §[p10 18]

To **load a `multipart/x-mixed-replace` document**, given navigation params[p975] *navigationParams*, source snapshot params[p975] *sourceSnapshotParams*, and origin[p869] *initiatorOrigin*:

1. Parse *navigationParams*'s response[p976]'s body using the rules for multipart types. [RFC2046][p1416]

2. Let *firstPartNavigationParams* be a copy of *navigationParams*.

3. Set *firstPartNavigationParams*'s response[p976] to a new response representing the first part of *navigationParams*'s response[p976]'s body's multipart stream.

4. Let *document* be the result of loading a document[p1001] given *firstPartNavigationParams*, *sourceSnapshotParams*, and *initiatorOrigin*.

   For each additional body part obtained from *navigationParams*'s response[p976], the user agent must navigate[p977] *document*'s node navigable[p953] to *navigationParams*'s request[p976]'s URL, using *document*, with *response*[p977] set to *navigationParams*'s response[p976] and *historyHandling*[p977] set to "`replace`[p976]".

5. Return *document*.

For the purposes of algorithms processing these body parts as if they were complete stand-alone resources, the user agent must act as if there were no more bytes for those resources whenever the boundary following the body part is reached.

Note

Thus, `load`[p1407] events (and for that matter `unload`[p1407] events) do fire for each body part loaded.

7.5.6 Loading media documents §[p10 19]

To **load a media document**, given *navigationParams* and a string *type*:

1. Let *document* be the result of creating and initializing a `Document` object[p1013] given "`html`", *type*, and *navigationParams*.

2. Set *document*'s mode to "`no-quirks`".

3. Populate with `html`/`head`/`body`[p1016] given *document*.

4. Append an element *host element* for the media, as described below, to the `body`[p199] element.

5. Set the appropriate attribute of the element *host element*, as described below, to the address of the image, video, or audio resource.

6. User agents may add content to the `head`[p168] element of *document*, or attributes to *host element*, e.g., to link to a style sheet, to provide a script, to give the document a `title`[p169], or to make the media autoplay[p427].

7. Process link headers[p181] given *document*, *navigationParams*'s response[p976], and "`media`".

8. Act as if the user agent had stopped parsing[p1296] *document*.

9. Return *document*.

The element *host element* to create for the media is the element given in the table below in the second cell of the row whose first cell describes the media. The appropriate attribute to set is the one given by the third cell in that same row.

Type of media	Element for the media	Appropriate attribute
Image	`img`[p338]	`src`[p340]
Video	`video`[p398]	`src`[p408]
Audio	`audio`[p402]	`src`[p408]

Before any script execution occurs, the user agent must wait for scripts may run for the newly-created document[p1010] to be true for the `Document`[p127].

7.5.7 Loading a document for inline content that doesn't have a DOM §[p10 19]

When the user agent is to create a document to display a user agent page or PDF viewer inline, provided a navigable[p952] *navigable*, a navigation ID[p976] *navigationId*, a `NavigationTimingType` *navTimingType*, the user agent should:

1. Let *origin* be a new opaque origin[p869].

2. Let *coop* be a new cross-origin opener policy[p874].

3. Let *coopEnforcementResult* be a new cross-origin opener policy enforcement result[p876] with

   url[p876]
   response's URL
   origin[p876]
   origin
   cross-origin opener policy[p876]
   coop

4. Let *navigationParams* be a new navigation params[p975] with

   id[p975]
   navigationId
   navigable[p976]
   navigable
   request[p976]
   null
   response[p976]
   a new response
   origin[p976]
   origin
   fetch controller[p976]
   null
   commit early hints[p976]
   null
   COOP enforcement result[p976]
   coopEnforcementResult
   reserved environment[p976]
   null
   policy container[p976]
   a new policy container[p888]
   final sandboxing flag set[p976]
   an empty set
   cross-origin opener policy[p976]
   coop
   navigation timing type[p976]
   navTimingType
   about base URL[p976]
   null

5. Let *document* be the result of creating and initializing a `Document` object[p1013] given "`html`", "`text/html`", and *navigationParams*.

6. Either associate *document* with a custom rendering that is not rendered using the normal `Document`[p127] rendering rules, or mutate *document* until it represents the content the user agent wants to render.

7. Return *document*.

Note

Because we ensure the resulting `Document`[p127]*'s origin is opaque*[p869]*, and the resulting* `Document`[p127] *cannot run script with access to the DOM, the existence and properties of this* `Document`[p127] *are not observable to web developer code. This means that most of the above values, e.g., the* `text/html`[p1380] *type, do not matter. Similarly, most of the items in* navigationParams *don't have any observable effect, besides preventing the* `Document`*-creation algorithm*[p1013] *from getting confused, and so are set to default values.*

Once the page has been set up, the user agent must act as if it had stopped parsing[p1296].

7.5.8 Finishing the loading process §[p1020]

A `Document`[p127] has a **completely loaded time** (a time or null), which is initially null.

A Document[p127] is considered **completely loaded** if its completely loaded time[p1020] is non-null.

To **completely finish loading** a Document[p127] *document*:

1. Assert: *document*'s browsing context[p961] is non-null.
2. Set *document*'s completely loaded time[p1020] to the current time.
3. Let *container* be *document*'s node navigable[p953]'s container[p955].

   Note

   This will be null in the case where document *is the initial* about:blank[p128] Document[p127] *in a* frame[p1369] *or* iframe[p383]*, since at the point of browsing context creation[p962] which calls this algorithm, the container relationship has not yet been established. (That happens in a subsequent step of create a new child navigable[p955].)*

   The consequence of this is that the following steps do nothing, i.e., we do not fire an asynchronous load[p1407] *event on the container element for such cases. Instead, a synchronous* load[p1407] *event is fired in a special initial-insertion case when processing the* iframe *attributes[p385].*

4. If *container* is an iframe[p383] element, then queue an element task[p1073] on the DOM manipulation task source[p1080] given *container* to run the iframe load event steps[p387] given *container*.
5. Otherwise, if *container* is non-null, then queue an element task[p1073] on the DOM manipulation task source[p1080] given *container* to fire an event named load[p1407] at *container*.

7.5.9 Unloading documents §[p1021]

A Document[p127] has a ***salvageable*** state, which must initially be true, and a **page showing** flag, which must initially be false. The page showing[p1021] flag is used to ensure that scripts receive pageshow[p1407] and pagehide[p1407] events in a consistent manner (e.g. that they never receive two pagehide[p1407] events in a row without an intervening pageshow[p1407], or vice versa).

A Document[p127] has a DOMHighResTimeStamp **suspension time**, initially 0.

A Document[p127] has a list of **suspended timer handles**, initially empty.

Event loops[p1071] have a **termination nesting level** counter, which must initially be 0.

Document[p127] objects have an **unload counter**, which is used to ignore certain operations while the below algorithms run. Initially, the counter must be set to zero.

To **unload** a Document[p127] *oldDocument*, given an optional Document[p127] *newDocument*:

1. Assert: this is running as part of a task[p1071] queued on *oldDocument*'s event loop[p1071].
2. Let *unloadTimingInfo* be a new document unload timing info[p131].
3. If *newDocument* is not given, then set *unloadTimingInfo* to null.

   Note

   In this case there is no new document that needs to know about how long it took oldDocument *to unload.*

4. Otherwise, if *newDocument*'s event loop[p1071] is not *oldDocument*'s event loop[p1071], then the user agent may be unloading[p1021] *oldDocument* in parallel[p43]. In that case, the user agent should set *unloadTimingInfo* to null.

   Note

   In this case newDocument'*s loading is not impacted by how long it takes to unload* oldDocument*, so it would be meaningless to communicate that timing info.*

5. Let *intendToKeepInBfcache* be true if the user agent intends to keep *oldDocument* alive in a session history entry[p968], such that it can later be used for history traversal[p969].

   This must be false if *oldDocument* is not *salvageable[p1021]*, or if there are any descendants of *oldDocument* which the user agent does not intend to keep alive in the same way (including due to their lack of *salvageability[p1021]*).

6. Let *eventLoop* be *oldDocument*'s relevant agent[p1029]'s event loop[p1071].
7. Increase *eventLoop*'s termination nesting level[p1021] by 1.
8. Increase *oldDocument*'s unload counter[p1021] by 1.
9. If *intendToKeepInBfcache* is false, then set *oldDocument*'s *salvageable*[p1021] state to false.
10. If *oldDocument*'s page showing[p1021] is true:
    1. Set *oldDocument*'s page showing[p1021] to false.
    2. Fire a page transition event[p951] named `pagehide`[p1407] at *oldDocument*'s relevant global object[p1039] with *oldDocument*'s *salvageable*[p1021] state.
    3. Update the visibility state[p807] of *oldDocument* to "`hidden`".
11. If *unloadTimingInfo* is not null, then set *unloadTimingInfo*'s unload event start time[p131] to the current high resolution time given *newDocument*'s relevant global object[p1039], coarsened given *oldDocument*'s relevant settings object[p1039]'s cross-origin isolated capability[p1032].
12. If *oldDocument*'s *salvageable*[p1021] state is false, then fire an event named `unload`[p1407] at *oldDocument*'s relevant global object[p1039], with *legacy target override flag* set.
13. If *unloadTimingInfo* is not null, then set *unloadTimingInfo*'s unload event end time[p131] to the current high resolution time given *newDocument*'s relevant global object[p1039], coarsened given *oldDocument*'s relevant settings object[p1039]'s cross-origin isolated capability[p1032].
14. Decrease *eventLoop*'s termination nesting level[p1021] by 1.
15. Set *oldDocument*'s suspension time[p1021] to the current high resolution time given *document*'s relevant global object[p1039].
16. Set *oldDocument*'s suspended timer handles[p1021] to the result of getting the keys for the map of active timers[p1101].
17. Set *oldDocument*'s has been scrolled by the user[p1013] to false.
18. Run any unloading document cleanup steps[p1022] for *oldDocument* that are defined by this specification and other applicable specifications[p70].
19. If *oldDocument*'s *salvageable*[p1021] state is false, then destroy[p1023] *oldDocument*.
20. Decrease *oldDocument*'s unload counter[p1021] by 1.
21. If *newDocument* is given, *newDocument*'s was created via cross-origin redirects[p131] is false, and *newDocument*'s origin is the same[p870] as *oldDocument*'s origin, then set *newDocument*'s previous document unload timing[p131] to *unloadTimingInfo*.

This specification defines the following **unloading document cleanup steps**. Other specifications can define more. Given a `Document`[p127] *document*:

1. Let *window* be *document*'s relevant global object[p1039].
2. For each `WebSocket` object *webSocket* whose relevant global object[p1039] is *window*, make disappear *webSocket*.

   If this affected any `WebSocket` objects, then set *document*'s *salvageable*[p1021] state to false.
3. For each `WebTransport` object *transport* whose relevant global object[p1039] is *window*, run the context cleanup steps given *transport*.
4. If *document*'s *salvageable*[p1021] state is false, then:
    1. For each `EventSource`[p1130] object *eventSource* whose relevant global object[p1039] is equal to *window*, forcibly close[p1137] *eventSource*.
    2. Clear *window*'s map of active timers[p1101].

It would be better if specification authors sent a pull request to add calls from here into their specifications directly, instead of using the unloading document cleanup steps[p1022] hook, to ensure well-defined cross-specification call order. As of the time of this writing the following specifications are known to have unloading document cleanup steps[p1022], which will be run in an unspecified

order: *Fullscreen API*, *Web NFC*, *WebDriver BiDi*, *Compute Pressure*, *File API*, *Media Capture and Streams*, *Picture-in-Picture*, *Screen Orientation*, *Service Workers*, *WebLocks API*, *WebAudio API*, *WebRTC*. [FULLSCREEN][p1413] [WEBNFC][p1418] [WEBDRIVERBIDI][p1418] [COMPUTEPRESSURE][p1410] [FILEAPI][p1413] [MEDIASTREAM][p1414] [PICTUREINPICTURE][p1415] [SCREENORIENTATION][p1416] [SW][p1417] [WEBLOCKS][p1418] [WEBAUDIO][p1418] [WEBRTC][p1418]

Issue #8906 tracks the work to make the order of these steps clear.

7.5.10 Destroying documents §[p1023]

To **destroy** a `Document`[p127] *document*:

1. Destroy[p1023] the active documents[p952] of each of *document*'s descendant navigables[p957]. In what order?
2. Set *document*'s *salvageable*[p1021] state to false.
3. Run any unloading document cleanup steps[p1022] for *document* that are defined by this specification and other applicable specifications[p70].
4. Abort[p1023] *document*.
5. Remove any tasks[p1071] whose document[p1072] is *document* from any task queue[p1071] (without running those tasks).
6. Set *document*'s browsing context[p961] to null.
7. Set *document*'s node navigable[p953]'s active session history entry[p952]'s document state[p968]'s document[p969] to null.
8. Remove *document* from the owner set[p1166] of each `WorkerGlobalScope`[p1166] object whose set contains *document*.
9. For each *workletGlobalScope* in *document*'s worklet global scopes[p1189], terminate[p1186] *workletGlobalScope*.

Note

Even after destruction, the `Document`[p127] *object itself might still be accessible to script, in the case where we are destroying a child navigable*[p958].

7.5.11 Aborting a document load §[p1023]

To **abort** a `Document`[p127] *document*:

1. Abort[p1023] the active documents[p952] of each of *document*'s descendant navigables[p957]. In what order? If this results in any of those `Document`[p127] objects having their *salvageable*[p1021] state set to false, then set *document*'s *salvageable*[p1021] state to false also.
2. Cancel any instances of the fetch algorithm in the context of *document*, discarding any tasks[p1071] queued[p1072] for them, and discarding any further data received from the network for them. If this resulted in any instances of the fetch algorithm being canceled or any queued[p1072] tasks[p1071] or any network data getting discarded, then set *document*'s *salvageable*[p1021] state to false.
3. If *document*'s navigation id[p128] is non-null, then:
    1. Invoke WebDriver BiDi navigation aborted with *document*'s browsing context[p961], and new WebDriver BiDi navigation status whose whose id is *document*'s navigation id[p128], status is "`canceled`", and url is *document*'s URL.
    2. Set *document*'s navigation id[p128] to null.
4. If *document* has an active parser[p131], then:
    1. Set *document*'s active parser was aborted[p1097] to true.
    2. Abort that parser[p1297].
    3. Set *document*'s *salvageable*[p1021] state to false.

To **stop loading** a navigable[p952] *navigable*:

1. Let *document* be *navigable*'s active document[p952].
2. If *document*'s unload counter[p1021] is 0, and *navigable*'s ongoing navigation[p989] is a navigation ID[p976], then set the ongoing navigation[p989] for *navigable* to null.

   Note

   This will have the effect of aborting any ongoing navigations of navigable*, since at certain points during navigation, changes to the ongoing navigation[p989] will cause further work to be abandoned.*

3. Abort[p1023] *document*.

Through their user interface[p1026], user agents also allow stopping traversals, i.e. cases where the ongoing navigation[p989] is "traversal". The above algorithm does not account for this. (On the other hand, user agents do not allow window.stop()[p898] to stop traversals, so the above algorithm is correct for that caller.) See issue #6905.

MDN

7.6 The `X-Frame-Options`[p1024] header §[p1024]

The `X-Frame-Options` HTTP response header is a legacy way of controlling whether and how a Document[p127] may be loaded inside of a child navigable[p955]. It is obsoleted by the frame-ancestors CSP directive, which provides more granular control over the same situations. It was originally defined in *HTTP Header Field X-Frame-Options*, but the definition and processing model here supersedes that document. [CSP][p1411] [RFC7034][p1416]

Note

In particular, HTTP Header Field X-Frame-Options *specified an* `ALLOW-FROM` *variant of the header, but that is not to be implemented.*

Note

Per the below processing model, if both a CSP frame-ancestors *directive and an* `X-Frame-Options`[p1024] *header are used in the same response, then* `X-Frame-Options`[p1024] *is ignored.*

For web developers and conformance checkers, its value ABNF is:

```
X-Frame-Options = "DENY" / "SAMEORIGIN"
```

To **check a navigation response's adherence to `X-Frame-Options`**, given a response *response*, a navigable[p952] *navigable*, a CSP list *cspList*, and an origin[p869] *destinationOrigin*:

1. If *navigable* is not a child navigable[p955], then return true.
2. For each *policy* of *cspList*:
   1. If *policy*'s disposition is not "enforce", then continue.
   2. If *policy*'s directive set contains a frame-ancestors directive, then return true.
3. Let *rawXFrameOptions* be the result of getting, decoding, and splitting `X-Frame-Options`[p1024] from *response*'s header list.
4. Let *xFrameOptions* be a new set.
5. For each *value* of *rawXFrameOptions*, append *value*, converted to ASCII lowercase, to *xFrameOptions*.
6. If *xFrameOptions*'s size is greater than 1, and *xFrameOptions* contains any of "deny", "allowall", or "sameorigin", then return false.

   Note

   The intention here is to block any attempts at applying `X-Frame-Options`[p1024] *which were trying to do something valid, but appear confused.*

Note

This is the only impact of the legacy `ALLOWALL` value on the processing model.

7. If *xFrameOptions*'s size is greater than 1, then return true.

Note

This means it contains multiple invalid values, which we treat the same way as if the header was omitted entirely.

8. If *xFrameOptions*[0] is "`deny`", then return false.
9. If *xFrameOptions*[0] is "`sameorigin`", then:
    1. Let *containerDocument* be *navigable*'s container document[p955].
    2. While *containerDocument* is not null:
        1. If *containerDocument*'s origin is not same origin[p870] with *destinationOrigin*, then return false.
        2. Set *containerDocument* to *containerDocument*'s container document[p955].
10. Return true.

Note

If we've reached this point then we have a lone invalid value (which could potentially be one the legacy `ALLOWALL` or `ALLOW-FROM` forms). These are treated as if the header were omitted entirely.

Example

The following table illustrates the processing of various values for the header, including non-conformant ones:

`X-Frame-Options`[p1024]	Valid	Result
`DENY`	✓	embedding disallowed
`SAMEORIGIN`	✓	same-origin embedding allowed
`INVALID`	×	embedding allowed
`ALLOWALL`	×	embedding allowed
`ALLOW-FROM=https://example.com/`	×	embedding allowed (from anywhere)

Example

The following table illustrates how various non-conformant cases involving multiple values are processed:

`X-Frame-Options`[p1024]	Result
`SAMEORIGIN, SAMEORIGIN`	same-origin embedding allowed
`SAMEORIGIN, DENY`	embedding disallowed
`SAMEORIGIN,`	embedding disallowed
`SAMEORIGIN, ALLOWALL`	embedding disallowed
`SAMEORIGIN, INVALID`	embedding disallowed
`ALLOWALL, INVALID`	embedding disallowed
`ALLOWALL,`	embedding disallowed
`INVALID, INVALID`	embedding allowed

The same results are obtained whether the values are delivered in a single header whose value is comma-delimited, or in multiple headers.

7.7 The `Refresh`[p1025] header §[p1025]

The `Refresh` HTTP response header is the HTTP-equivalent to a `meta`[p184] element with an `http-equiv`[p190] attribute in the Refresh state[p191]. It takes the same value[p192] and works largely the same. Its processing model is detailed in create and initialize a `Document` object[p1013].

7.8 Browser user interface considerations §p1026

Browser user agents should provide the ability to navigate[p977], reload[p990], and stop loading[p1024] any top-level traversable[p953] in their top-level traversable set[p954].

Example

For example, via a location bar and reload/stop button UI.

Browser user agents should provide the ability to traverse by a delta[p990] any top-level traversable[p953] in their top-level traversable set[p954].

Example

For example, via back and forward buttons, possibly including long-press abilities to change the delta.

It is suggested that such user agents allow traversal by deltas greater than one, to avoid letting a page "trap" the user by stuffing the session history with spurious entries. (For example, via repeated calls to `history.pushState()`[p917] or fragment navigations[p984].)

Note

Some user agents have heuristics for translating a single "back" or "forward" button press into a larger delta, specifically to overcome such abuses. We are contemplating specifying these heuristics in issue #7832.

Browser user agents should offer users the ability to create a fresh top-level traversable[p954], given a user-provided or user agent-determined initial URL.

Example

For example, via a "new tab" or "new window" button.

Browser user agents should offer users the ability to arbitrarily close[p958] any top-level traversable[p953] in their top-level traversable set[p954].

Example

For example, by clicking a "close tab" button.

Browser user agents may provide ways for the user to explicitly cause any navigable[p952] (not just a top-level traversable[p953]) to navigate[p977], reload[p990], or stop loading[p1024].

Example

For example, via a context menu.

Browser user agents may provide the ability for users to destroy a top-level traversable[p958].

Example

For example, by force-closing a window containing one or more such top-level traversables[p953].

When a user requests a reload[p990] of a navigable[p952] whose active session history entry[p952]'s document state[p968]'s resource[p969] is a POST resource[p970], the user agent should prompt the user to confirm the operation first, since otherwise transactions (e.g., purchases or database modifications) could be repeated.

When a user requests a reload[p990] of a navigable[p952], user agents may provide a mechanism for ignoring any caches when reloading.

All calls to navigate[p977] initiated by the mechanisms mentioned above must have the *userInvolvement*[p977] argument set to "`browser UI`[p977]".

All calls to reload[p990] initiated by the mechanisms mentioned above must have the *userInvolvement*[p990] argument set to "`browser`

UI[p977]".

All calls to traverse the history by a delta[p990] initiated by the mechanisms mentioned above must not pass a value for the *sourceDocument*[p990] argument.

The above recommendations, and the data structures in this specification, are not meant to place restrictions on how user agents represent the session history to the user.

For example, although a top-level traversable[p953]'s session history entries[p953] are stored and maintained as a list, and the user agent is recommended to give an interface for traversing that list by a delta[p990], a novel user agent could instead or in addition present a tree-like view, with each page having multiple "forward" pages that the user can choose between.

Similarly, although session history for all descendant navigables[p952] is stored in their traversable navigable[p953], user agents could present the user with a more nuanced per-navigable[p952] view of the session history.

Browser user agents may use a top-level browsing context[p964]'s is popup[p961] boolean for the following purposes:

- Deciding whether or not to provide a minimal web browser user interface for the corresponding top-level traversable[p953].
- Performing the optional steps in set up browsing context features.

In both cases user agents might additionally incorporate user preferences, or present a choice as to whether to go down the popup route.

User agents that provides a minimal user interface for such popups are encouraged to not hide the browser's location bar.

8 Web application APIs §p10 28

8.1 Scripting §p10 28

8.1.1 Introduction §p10 28

Various mechanisms can cause author-provided executable code to run in the context of a document. These mechanisms include, but are probably not limited to:

- Processing of `script`p638 elements.
- Navigating to `javascript:` URLsp982.
- Event handlers, whether registered through the DOM using `addEventListener()`, by explicit event handler content attributesp1084, by event handler IDL attributesp1084, or otherwise.
- Processing of technologies like SVG that have their own scripting features.

8.1.2 Agents and agent clusters §p10 28

8.1.2.1 Integration with the JavaScript agent formalism §p10 28

JavaScript defines the concept of an agent. This section gives the mapping of that language-level concept on to the web platform.

Note

Conceptually, the agent concept is an architecture-independent, idealized "thread" in which JavaScript code runs. Such code can involve multiple globals/realmsp1033 that can synchronously access each other, and thus needs to run in a single execution thread.

Two `Window`p892 objects having the same agent does not indicate they can directly access all objects created in each other's realms. They would have to be same origin-domainp870; see IsPlatformObjectSameOriginp890.

The following types of agents exist on the web platform:

Similar-origin window agent

Contains various `Window`p892 objects which can potentially reach each other, either directly or by using `document.domain`p872.

If the encompassing agent cluster's is origin-keyedp1029 is true, then all the `Window`p892 objects will be same originp870, can reach each other directly, and `document.domain`p872 will no-op.

Note

Two `Window`p892 objects that are same originp870 can be in different similar-origin window agentsp1028, for instance if they are each in their own browsing context groupp965.

Dedicated worker agent

Contains a single `DedicatedWorkerGlobalScope`p1168.

Shared worker agent

Contains a single `SharedWorkerGlobalScope`p1168.

Service worker agent

Contains a single `ServiceWorkerGlobalScope`.

Worklet agent

Contains a single `WorkletGlobalScope`p1184 object.

Note

Although a given worklet can have multiple realms, each such realm needs its own agent, as each realm can be executing code independently and at the same time as the others.

Only shared[p1028] and dedicated worker agents[p1028] allow the use of JavaScript `Atomics` APIs to potentially block.

To **create an agent**, given a boolean *canBlock*:

1. Let *signifier* be a new unique internal value.
2. Let *candidateExecution* be a new candidate execution.
3. Let *agent* be a new agent whose [[CanBlock]] is *canBlock*, [[Signifier]] is *signifier*, [[CandidateExecution]] is *candidateExecution*, and [[IsLockFree1]], [[IsLockFree2]], and [[LittleEndian]] are set at the implementation's discretion.
4. Set *agent*'s event loop[p1071] to a new event loop[p1071].
5. Return *agent*.

For a realm *realm*, the agent whose [[Signifier]] is *realm*.[[AgentSignifier]] is **the realm's agent**.

The **relevant agent** for a platform object *platformObject* is *platformObject*'s relevant realm[p1039]'s agent[p1029].

Note

The agent equivalent of the current realm is the surrounding agent.

8.1.2.2 Integration with the JavaScript agent cluster formalism §[p1029]

JavaScript also defines the concept of an agent cluster, which this standard maps to the web platform by placing agents appropriately when they are created using the obtain a similar-origin window agent[p1029] or obtain a worker/worklet agent[p1030] algorithms.

The agent cluster concept is crucial for defining the JavaScript memory model, and in particular among which agents the backing data of `SharedArrayBuffer` objects can be shared.

Note

Conceptually, the agent cluster concept is an architecture-independent, idealized "process boundary" that groups together multiple "threads" (agents). The agent clusters defined by the specification are generally more restrictive than the actual process boundaries implemented in user agents. By enforcing these idealized divisions at the specification level, we ensure that web developers see interoperable behavior with regard to shared memory, even in the face of varying and changing user agent process models.

An agent cluster has an associated **cross-origin isolation mode**, which is a cross-origin isolation mode[p965]. It is initially "none[p965]".

An agent cluster has an associated **is origin-keyed** (a boolean), which is initially false.

The following defines the allocation of the agent clusters of similar-origin window agents[p1028].

An **agent cluster key** is a site[p870] or tuple origin[p869]. Without web developer action to achieve origin-keyed agent clusters[p873], it will be a site[p870].

Note

An equivalent formulation is that an agent cluster key[p1029] can be a scheme-and-host[p870] or an origin[p869].

To **obtain a similar-origin window agent**, given an origin[p869] *origin*, a browsing context group[p965] *group*, and a boolean *requestsOAC*, run these steps:

1. Let *site* be the result of obtaining a site[p870] with *origin*.
2. Let *key* be *site*.

3. If *group*'s cross-origin isolation mode[p965] is not "none[p965]", then set *key* to *origin*.
4. Otherwise, if *group*'s historical agent cluster key map[p965][*origin*] exists, then set *key* to *group*'s historical agent cluster key map[p965][*origin*].
5. Otherwise:
    1. If *requestsOAC* is true, then set *key* to *origin*.
    2. Set *group*'s historical agent cluster key map[p965][*origin*] to *key*.
6. If *group*'s agent cluster map[p965][*key*] does not exist, then:
    1. Let *agentCluster* be a new agent cluster.
    2. Set *agentCluster*'s cross-origin isolation mode[p1029] to *group*'s cross-origin isolation mode[p965].
    3. Set *agentCluster*'s is origin-keyed[p1029] to true if *key* equals *origin*; otherwise false.
    4. Add the result of creating an agent[p1029], given false, to *agentCluster*.
    5. Set *group*'s agent cluster map[p965][*key*] to *agentCluster*.
7. Return the single similar-origin window agent[p1028] contained in *group*'s agent cluster map[p965][*key*].

Note

This means that there is only one similar-origin window agent[p1028] per browsing context agent cluster. (However, dedicated worker[p1028] and worklet agents[p1028] might be in the same cluster.)

The following defines the allocation of the agent clusters of all other types of agents.

To **obtain a worker/worklet agent**, given an environment settings object[p1032] or null *outside settings*, a boolean *isTopLevel*, and a boolean *canBlock*, run these steps:

1. Let *agentCluster* be null.
2. If *isTopLevel* is true, then:
    1. Set *agentCluster* to a new agent cluster.
    2. Set *agentCluster*'s is origin-keyed[p1029] to true.

    Note

    These workers can be considered to be origin-keyed. However, this is not exposed through any APIs (in the way that `originAgentCluster`[p873] exposes the origin-keyedness for windows).
3. Otherwise:
    1. Assert: *outside settings* is not null.
    2. Let *ownerAgent* be *outside settings*'s realm[p1033]'s agent[p1029].
    3. Set *agentCluster* to the agent cluster which contains *ownerAgent*.
4. Let *agent* be the result of creating an agent[p1029] given *canBlock*.
5. Add *agent* to *agentCluster*.
6. Return *agent*.

To **obtain a dedicated/shared worker agent**, given an environment settings object[p1032] *outside settings* and a boolean *isShared*, return the result of obtaining a worker/worklet agent[p1030] given *outside settings*, *isShared*, and true.

To **obtain a worklet agent**, given an environment settings object[p1032] *outside settings*, return the result of obtaining a worker/worklet agent[p1030] given *outside settings*, false, and false.

To **obtain a service worker agent**, return the result of obtaining a worker/worklet agent[p1030] given null, true, and false.

Example

The following pairs of global objects are each within the same agent cluster, and thus can use SharedArrayBuffer instances to share memory with each other:

- A Window[p892] object and a dedicated worker that it created.
- A worker (of any type) and a dedicated worker it created.
- A Window[p892] object *A* and the Window[p892] object of an iframe[p383] element that *A* created that could be same origin-domain[p870] with *A*.
- A Window[p892] object and a same origin-domain[p870] Window[p892] object that opened it.
- A Window[p892] object and a worklet that it created.

The following pairs of global objects are *not* within the same agent cluster, and thus cannot share memory:

- A Window[p892] object and a shared worker it created.
- A worker (of any type) and a shared worker it created.
- A Window[p892] object and a service worker it created.
- A Window[p892] object and the Window[p892] object of an iframe[p383] element that *A* created that cannot be same origin-domain[p870] with *A*.
- Any two Window[p892] objects with no opener or ancestor relationship. This holds even if the two Window[p892] objects are same origin[p870].

8.1.3 Realms and their counterparts §[p10 31]

The JavaScript specification introduces the realm concept, representing a global environment in which script is run. Each realm comes with an implementation-defined global object[p1033]; much of this specification is devoted to defining that global object and its properties.

For web specifications, it is often useful to associate values or algorithms with a realm/global object pair. When the values are specific to a particular type of realm, they are associated directly with the global object in question, e.g., in the definition of the Window[p892] or WorkerGlobalScope[p1166] interfaces. When the values have utility across multiple realms, we use the environment settings object[p1032] concept.

Finally, in some cases it is necessary to track associated values before a realm/global object/environment settings object even comes into existence (for example, during navigation[p977]). These values are tracked in the environment[p1031] concept.

8.1.3.1 Environments §[p10 31]

An **environment** is an object that identifies the settings of a current or potential execution environment (i.e., a navigation params[p975]'s reserved environment[p976] or a request's reserved client). An environment[p1031] has the following fields:

An *id*

An opaque string that uniquely identifies this environment[p1031].

A *creation URL*

A URL that represents the location of the resource with which this environment[p1031] is associated.

Note

In the case of a Window[p892] environment settings object[p1032], this URL might be distinct from its global object[p1033]'s associated Document[p894]'s URL, due to mechanisms such as history.pushState()[p917] which modify the latter.

A *top-level creation URL*

Null or a URL that represents the creation URL[p1031] of the "top-level" environment[p1031]. It is null for workers and worklets.

A *top-level origin*

A for now implementation-defined value, null, or an origin[p869]. For a "top-level" potential execution environment it is null (i.e., when there is no response yet); otherwise it is the "top-level" environment[p1031]'s origin[p1032]. For a dedicated worker or worklet it is the top-level origin[p1031] of its creator. For a shared or service worker it is an implementation-defined value.

Note

This is distinct from the top-level creation URL[p1031]'s origin when sandboxing, workers, and worklets are involved.

A *target browsing context*

Null or a target browsing context[p961] for a navigation request.

An *active service worker*

Null or a service worker that controls the environment[p1031].

An *execution ready flag*

A flag that indicates whether the environment setup is done. It is initially unset.

Specifications may define **environment discarding steps** for environments. The steps take an environment[p1031] as input.

Note

The environment discarding steps[p1032] are run for only a select few environments: the ones that will never become execution ready because, for example, they failed to load.

8.1.3.2 Environment settings objects §[p1032]

An **environment settings object** is an environment[p1031] that additionally specifies algorithms for:

A *realm execution context*

A JavaScript execution context shared by all scripts[p638] that use this settings object, i.e., all scripts in a given realm. When we run a classic script[p1050] or run a module script[p1051], this execution context becomes the top of the JavaScript execution context stack, on top of which another execution context specific to the script in question is pushed. (This setup ensures ParseScript and Source Text Module Record's Evaluate know which realm to use.)

A *module map*

A module map[p1068] that is used when importing JavaScript modules.

An *API URL character encoding*

A character encoding used to encode URLs by APIs called by scripts that use this environment settings object[p1032].

An *API base URL*

A URL used by APIs called by scripts that use this environment settings object[p1032] to parse URLs[p95].

An *origin*

An origin[p869] used in security checks.

A *policy container*

A policy container[p888] containing policies used for security checks.

A *cross-origin isolated capability*

A boolean representing whether scripts that use this environment settings object[p1032] are allowed to use APIs that require cross-origin isolation.

A *time origin*

A number used as the baseline for performance-related timestamps. [HRT][p1413]

An environment settings object[p1032] also has an **outstanding rejected promises weak set** and an **about-to-be-notified rejected promises list**, used to track unhandled promise rejections[p1054]. The outstanding rejected promises weak set[p1032] must not create strong references to any of its members, and implementations are free to limit its size, e.g. by removing old entries from it when new ones are added.

An environment settings object[p1032]'s **responsible event loop** is its global object[p1033]'s relevant agent[p1029]'s event loop[p1071].

8.1.3.3 Realms, settings objects, and global objects §[p1033]

A **global object** is a JavaScript object that is the [[GlobalObject]] field of a realm.

> **Note**
> *In this specification, all realms are created[p1033] with global objects[p1033] that are either* `Window`[p892] *or* `WorkerGlobalScope`[p1166] *objects.*

There is always a 1-to-1-to-1 mapping between realms, global objects[p1033], and environment settings objects[p1032]:

- A realm has a [[HostDefined]] field, which contains **the realm's settings object**.
- A realm has a [[GlobalObject]] field, which contains **the realm's global object**.
- Each global object[p1033] in this specification is created during the creation[p1033] of a corresponding realm, known as **the global object's realm**.
- Each global object[p1033] in this specification is created alongside a corresponding environment settings object[p1032], known as its relevant settings object[p1039].
- An environment settings object[p1032]'s realm execution context[p1032]'s Realm component is **the environment settings object's realm**.
- An environment settings object[p1032]'s realm[p1033] then has a [[GlobalObject]] field, which contains **the environment settings object's global object**.

To **create a new realm** in an agent *agent*, optionally with instructions to create a global object or a global **this** binding (or both), the following steps are taken:

1. Perform InitializeHostDefinedRealm() with the provided customizations for creating the global object and the global **this** binding.
2. Let *realm execution context* be the running JavaScript execution context.

   > **Note**
   > *This is the JavaScript execution context created in the previous step.*

3. Remove *realm execution context* from the JavaScript execution context stack.
4. Let *realm* be *realm execution context*'s Realm component.
5. If *agent*'s agent cluster's cross-origin isolation mode[p1029] is "`none`[p965]", then:
   1. Let *global* be *realm*'s global object[p1033].
   2. Let *status* be ! *global*.[[Delete]]("`SharedArrayBuffer`").
   3. Assert: *status* is true.

   > **Note**
   > *This is done for compatibility with web content and there is some hope that this can be removed in the future. Web developers can still get at the constructor through* `new WebAssembly.Memory({ shared:true, initial:0, maximum:0 }).buffer.constructor`*.*

6. Return *realm execution context*.

When defining algorithm steps throughout this specification, it is often important to indicate what realm is to be used—or, equivalently, what global object[p1033] or environment settings object[p1032] is to be used. In general, there are at least four possibilities:

Entry

This corresponds to the script that initiated the currently running script action: i.e., the function or script that the user agent called into when it called into author code.

Incumbent

This corresponds to the most-recently-entered author function or script on the stack, or the author function or script that originally

scheduled the currently-running callback.

Current

This corresponds to the currently-running function object, including built-in user-agent functions which might not be implemented as JavaScript. (It is derived from the current realm.)

Relevant

Every platform object has a relevant realm[p1039], which is roughly the realm in which it was created. When writing algorithms, the most prominent platform object whose relevant realm[p1039] might be important is the **this** value of the currently-running function object. In some cases, there can be other important relevant realms[p1039], such as those of any arguments.

Note how the entry[p1033], incumbent[p1033], and current[p1034] concepts are usable without qualification, whereas the relevant[p1034] concept must be applied to a particular platform object.

⚠Warning!

The incumbent[p1033] and entry[p1033] concepts should not be used by new specifications, as they are excessively complicated and unintuitive to work with. We are working to remove almost all existing uses from the platform: see issue #1430 for incumbent[p1033], and issue #1431 for entry[p1033].

In general, web platform specifications should use the relevant[p1034] concept, applied to the object being operated on (usually the **this** value of the current method). This mismatches the JavaScript specification, where current[p1034] is generally used as the default (e.g., in determining the realm whose `Array` constructor should be used to construct the result in `Array.prototype.map`). But this inconsistency is so embedded in the platform that we have to accept it going forward.

Example

Consider the following pages, with `a.html` being loaded in a browser window, `b.html` being loaded in an `iframe`[p383] as shown, and `c.html` and `d.html` omitted (they can simply be empty documents):

```
<!-- a.html -->
<!DOCTYPE html>
<html lang="en">
<title>Entry page</title>

<iframe src="b.html"></iframe>
<button onclick="frames[0].hello()">Hello</button>

<!--b.html -->
<!DOCTYPE html>
<html lang="en">
<title>Incumbent page</title>

<iframe src="c.html" id="c"></iframe>
<iframe src="d.html" id="d"></iframe>

<script>
  const c = document.querySelector("#c").contentWindow;
  const d = document.querySelector("#d").contentWindow;

  window.hello = () => {
    c.print.call(d);
  };
</script>
```

Each page has its own browsing context[p961], and thus its own realm, global object[p1033], and environment settings object[p1032].

When the `print()`[p1108] method is called in response to pressing the button in `a.html`, then:

- The entry realm[p1035] is that of `a.html`.
- The incumbent realm[p1036] is that of `b.html`.
- The current realm is that of `c.html` (since it is the `print()`[p1108] method from `c.html` whose code is running).

- The relevant realm[p1039] of the object on which the print()[p1108] method is being called is that of `d.html`.

Example

One reason why the relevant[p1034] concept is generally a better default choice than the current[p1034] concept is that it is more suitable for creating an object that is to be persisted and returned multiple times. For example, the navigator.getBattery() method creates promises in the relevant realm[p1039] for the Navigator[p1109] object on which it is invoked. This has the following impact: [BATTERY][p1410]

```
<!-- outer.html -->
<!DOCTYPE html>
<html lang="en">
<title>Relevant realm demo: outer page</title>
<script>
  function doTest() {
    const promise = navigator.getBattery.call(frames[0].navigator);

    console.log(promise instanceof Promise);           // logs false
    console.log(promise instanceof frames[0].Promise); // logs true

    frames[0].hello();
  }
</script>
<iframe src="inner.html" onload="doTest()"></iframe>

<!-- inner.html -->
<!DOCTYPE html>
<html lang="en">
<title>Relevant realm demo: inner page</title>
<script>
  function hello() {
    const promise = navigator.getBattery();

    console.log(promise instanceof Promise);        // logs true
    console.log(promise instanceof parent.Promise); // logs false
  }
</script>
```

If the algorithm for the getBattery() method had instead used the current realm, all the results would be reversed. That is, after the first call to getBattery() in `outer.html`, the Navigator[p1109] object in `inner.html` would be permanently storing a `Promise` object created in `outer.html`'s realm, and calls like that inside the `hello()` function would thus return a promise from the "wrong" realm. Since this is undesirable, the algorithm instead uses the relevant realm[p1039], giving the sensible results indicated in the comments above.

The rest of this section deals with formally defining the entry[p1033], incumbent[p1033], current[p1034], and relevant[p1034] concepts.

8.1.3.3.1 Entry §[p1035]

The process of calling scripts[p1050] will push or pop realm execution contexts[p1032] onto the JavaScript execution context stack, interspersed with other execution contexts.

With this in hand, we define the **entry execution context** to be the most recently pushed item in the JavaScript execution context stack that is a realm execution context[p1032]. The **entry realm** is the entry execution context[p1035]'s Realm component.

Then, the **entry settings object** is the environment settings object[p1033] of the entry realm[p1035].

Similarly, the **entry global object** is the global object[p1033] of the entry realm[p1035].

8.1.3.3.2 Incumbent §[p1036]

All JavaScript execution contexts must contain, as part of their code evaluation state, a **skip-when-determining-incumbent counter** value, which is initially zero. In the process of preparing to run a callback[p1036] and cleaning up after running a callback[p1036], this value will be incremented and decremented.

Every event loop[p1071] has an associated **backup incumbent settings object stack**, initially empty. Roughly speaking, it is used to determine the incumbent settings object[p1036] when no author code is on the stack, but author code is responsible for the current algorithm having been run in some way. The process of preparing to run a callback[p1036] and cleaning up after running a callback[p1036] manipulate this stack. [WEBIDL][p1418]

When Web IDL is used to invoke author code, or when HostEnqueuePromiseJob[p1065] invokes a promise job, they use the following algorithms to track relevant data for determining the incumbent settings object[p1036]:

To **prepare to run a callback** with an environment settings object[p1032] *settings*:

1. Push *settings* onto the backup incumbent settings object stack[p1036].
2. Let *context* be the topmost script-having execution context[p1036].
3. If *context* is not null, increment *context*'s skip-when-determining-incumbent counter[p1036].

To **clean up after running a callback** with an environment settings object[p1032] *settings*:

1. Let *context* be the topmost script-having execution context[p1036].

   Note

   This will be the same as the topmost script-having execution context[p1036] inside the corresponding invocation of prepare to run a callback[p1036].

2. If *context* is not null, decrement *context*'s skip-when-determining-incumbent counter[p1036].
3. Assert: the topmost entry of the backup incumbent settings object stack[p1036] is *settings*.
4. Remove *settings* from the backup incumbent settings object stack[p1036].

Here, the **topmost script-having execution context** is the topmost entry of the JavaScript execution context stack that has a non-null ScriptOrModule component, or null if there is no such entry in the JavaScript execution context stack.

With all this in place, the **incumbent settings object** is determined as follows:

1. Let *context* be the topmost script-having execution context[p1036].
2. If *context* is null, or if *context*'s skip-when-determining-incumbent counter[p1036] is greater than zero, then:
   1. Assert: the backup incumbent settings object stack[p1036] is not empty.

      Note

      This assert would fail if you try to obtain the incumbent settings object[p1036] from inside an algorithm that was triggered neither by calling scripts[p1050] nor by Web IDL invoking a callback. For example, it would trigger if you tried to obtain the incumbent settings object[p1036] inside an algorithm that ran periodically as part of the event loop[p1071], with no involvement of author code. In such cases the incumbent[p1033] concept cannot be used.

   2. Return the topmost entry of the backup incumbent settings object stack[p1036].
3. Return *context*'s Realm component's settings object[p1033].

Then, the **incumbent realm** is the realm[p1033] of the incumbent settings object[p1036].

Similarly, the **incumbent global object** is the global object[p1033] of the incumbent settings object[p1036].

The following series of examples is intended to make it clear how all of the different mechanisms contribute to the definition of the incumbent[p1036] concept:

Example

Consider the following starter example:

```
<!DOCTYPE html>
<iframe></iframe>
<script>
  frames[0].postMessage("some data", "*");
</script>
```

There are two interesting environment settings objects[p1032] here: that of `window`, and that of `frames[0]`. Our concern is: what is the incumbent settings object[p1036] at the time that the algorithm for `postMessage()`[p1140] executes?

It should be that of `window`, to capture the intuitive notion that the author script responsible for causing the algorithm to happen is executing in `window`, not `frames[0]`. This makes sense: the window post message steps[p1140] use the incumbent settings object[p1036] to determine the `source`[p1129] property of the resulting `MessageEvent`[p1128], and in this case `window` is definitely the source of the message.

Let us now explain how the steps given above give us our intuitively-desired result of `window`'s relevant settings object[p1039].

When the window post message steps[p1140] look up the incumbent settings object[p1036], the topmost script-having execution context[p1036] will be that corresponding to the `script`[p638] element: it was pushed onto the JavaScript execution context stack as part of ScriptEvaluation during the run a classic script[p1050] algorithm. Since there are no Web IDL callback invocations involved, the context's skip-when-determining-incumbent counter[p1036] is zero, so it is used to determine the incumbent settings object[p1036]; the result is the environment settings object[p1032] of `window`.

(Note how the environment settings object[p1032] of `frames[0]` is the relevant settings object[p1039] of this at the time the `postMessage()`[p1140] method is called, and thus is involved in determining the *target* of the message. Whereas the incumbent is used to determine the *source*.)

Example

Consider the following more complicated example:

```
<!DOCTYPE html>
<iframe></iframe>
<script>
  const bound = frames[0].postMessage.bind(frames[0], "some data", "*");
  window.setTimeout(bound);
</script>
```

This example is very similar to the previous one, but with an extra indirection through `Function.prototype.bind` as well as `setTimeout()`[p1102]. But, the answer should be the same: invoking algorithms asynchronously should not change the incumbent[p1033] concept.

This time, the result involves more complicated mechanisms:

When `bound` is converted to a Web IDL callback type, the incumbent settings object[p1036] is that corresponding to `window` (in the same manner as in our starter example above). Web IDL stores this as the resulting callback value's callback context.

When the task[p1071] posted by `setTimeout()`[p1102] executes, the algorithm for that task uses Web IDL to invoke the stored callback value. Web IDL in turn calls the above prepare to run a callback[p1036] algorithm. This pushes the stored callback context onto the backup incumbent settings object stack[p1036]. At this time (inside the timer task) there is no author code on the stack, so the topmost script-having execution context[p1036] is null, and nothing gets its skip-when-determining-incumbent counter[p1036] incremented.

Invoking the callback then calls `bound`, which in turn calls the `postMessage()`[p1140] method of `frames[0]`. When the `postMessage()`[p1140] algorithm looks up the incumbent settings object[p1036], there is still no author code on the stack, since the bound function just directly calls the built-in method. So the topmost script-having execution context[p1036] will be null: the JavaScript execution context stack only contains an execution context corresponding to `postMessage()`[p1140], with no ScriptEvaluation context or similar below it.

This is where we fall back to the backup incumbent settings object stack[p1036]. As noted above, it will contain as its topmost entry the relevant settings object[p1039] of `window`. So that is what is used as the incumbent settings object[p1036] while executing the

postMessage()[p1140] algorithm.

Example

Consider this final, even more convoluted example:

```
<!-- a.html -->
<!DOCTYPE html>
<button>click me</button>
<iframe></iframe>
<script>
const bound = frames[0].location.assign.bind(frames[0].location, "https://example.com/");
document.querySelector("button").addEventListener("click", bound);
</script>
```

```
<!-- b.html -->
<!DOCTYPE html>
<iframe src="a.html"></iframe>
<script>
  const iframe = document.querySelector("iframe");
  iframe.onload = function onLoad() {
    iframe.contentWindow.document.querySelector("button").click();
  };
</script>
```

Again there are two interesting environment settings objects[p1032] in play: that of `a.html`, and that of `b.html`. When the `location.assign()`[p912] method triggers the `Location`-object navigate[p909] algorithm, what will be the incumbent settings object[p1036]? As before, it should intuitively be that of `a.html`: the `click` listener was originally scheduled by `a.html`, so even if something involving `b.html` causes the listener to fire, the incumbent[p1033] responsible is that of `a.html`.

The callback setup is similar to the previous example: when `bound` is converted to a Web IDL callback type, the incumbent settings object[p1036] is that corresponding to `a.html`, which is stored as the callback's callback context.

When the `click()`[p814] method is called inside `b.html`, it dispatches a `click` event on the button that is inside `a.html`. This time, when the prepare to run a callback[p1036] algorithm executes as part of event dispatch, there *is* author code on the stack; the topmost script-having execution context[p1036] is that of the `onLoad` function, whose skip-when-determining-incumbent counter[p1036] gets incremented. Additionally, `a.html`'s environment settings object[p1032] (stored as the `EventHandler`[p1087]'s callback context) is pushed onto the backup incumbent settings object stack[p1036].

Now, when the `Location`-object navigate[p909] algorithm looks up the incumbent settings object[p1036], the topmost script-having execution context[p1036] is still that of the `onLoad` function (due to the fact we are using a bound function as the callback). Its skip-when-determining-incumbent counter[p1036] value is one, however, so we fall back to the backup incumbent settings object stack[p1036]. This gives us the environment settings object[p1032] of `a.html`, as expected.

Note that this means that even though it is the `iframe`[p383] inside `a.html` that navigates, it is `a.html` itself that is used as the source `Document`[p127], which determines among other things the request client. This is perhaps the only justifiable use of the incumbent concept on the web platform; in all other cases the consequences of using it are simply confusing and we hope to one day switch them to use current[p1034] or relevant[p1034] as appropriate.

8.1.3.3.3 Current §[p1038]

The JavaScript specification defines the current realm, also known as the "current Realm Record". [JAVASCRIPT][p1414]

Then, the **current settings object** is the environment settings object[p1033] of the current realm.

Similarly, the **current global object** is the global object[p1033] of the current realm.

8.1.3.3.4 Relevant §p10 39

The **relevant realm** for a platform object is the value of its [[Realm]] field.

Then, the **relevant settings object** for a platform object *o* is the environment settings object[p1033] of the relevant realm[p1039] for *o*.

Similarly, the **relevant global object** for a platform object *o* is the global object[p1033] of the relevant realm[p1039] for *o*.

8.1.3.4 Enabling and disabling scripting §p10 39

Scripting is enabled for an environment settings object[p1032] *settings* when all of the following conditions are true:

- The user agent supports scripting.
- The user has not disabled scripting for *settings* at this time. (User agents may provide users with the option to disable scripting globally, or in a finer-grained manner, e.g., on a per-origin basis, down to the level of individual environment settings objects[p1032].)
- Either *settings*'s global object[p1033] is not a `Window`[p892] object, or *settings*'s global object[p1033]'s associated `Document`[p894]'s active sandboxing flag set[p887] does not have its sandboxed scripts browsing context flag[p885] set.

Scripting is disabled for an environment settings object[p1032] when scripting is not enabled[p1039] for it, i.e., when any of the above conditions are false.

Scripting is enabled for a node *node* if *node*'s node document's browsing context[p961] is non-null, and scripting is enabled[p1039] for *node*'s relevant settings object[p1039].

Scripting is disabled for a node when scripting is not enabled[p1039], i.e., when its node document's browsing context[p961] is null or when scripting is disabled[p1039] for its relevant settings object[p1039].

8.1.3.5 Secure contexts §p10 39

An environment[p1031] *environment* is a **secure context** if the following algorithm returns true:

1. If *environment* is an environment settings object[p1032], then:
    1. Let *global* be *environment*'s global object[p1033].
    2. If *global* is a `WorkerGlobalScope`[p1166], then:
        1. If *global*'s owner set[p1166][0]'s relevant settings object[p1039] is a secure context[p1039], then return true.

        Note
        We only need to check the 0th item since they will necessarily all be consistent.

        2. Return false.
    3. If *global* is a `WorkletGlobalScope`[p1184], then return true.

    Note
    Worklets can only be created in secure contexts.

2. If the result of Is url potentially trustworthy? given *environment*'s top-level creation URL[p1031] is "`Potentially Trustworthy`", then return true.
3. Return false.

An environment[p1031] is a **non-secure context** if it is not a secure context[p1039].

8.1.4 Script processing model §p1040

8.1.4.1 Scripts §p1040

A **script** is one of three possible structs. All scripts have:

A *settings object*

An environment settings object[p1032], containing various settings that are shared with other scripts[p1040] in the same context.

A *record*

One of the following:

- a script record, for classic scripts[p1040];
- a Source Text Module Record, for JavaScript module scripts[p1040];
- a Synthetic Module Record, for CSS module scripts[p1040] and JSON module scripts[p1040]
- null, representing a parsing failure.

A *parse error*

A JavaScript value, which has meaning only if the record[p1040] is null, indicating that the corresponding script source text could not be parsed.

> **Note**
> *This value is used for internal tracking of immediate parse errors when creating scripts[p1048], and is not to be used directly. Instead, consult the error to rethrow[p1040] when determining "what went wrong" for this script.*

An *error to rethrow*

A JavaScript value representing an error that will prevent evaluation from succeeding. It will be re-thrown by any attempts to run[p1050] the script.

> **Note**
> *This could be the script's parse error[p1040], but in the case of a module script[p1040] it could instead be the parse error[p1040] from one of its dependencies, or an error from resolve a module specifier[p1056].*

> **Note**
> *Since this exception value is provided by the JavaScript specification, we know that it is never null, so we use null to signal that no error has occurred.*

Fetch options

A script fetch options[p1041], containing various options related to fetching this script or module scripts[p1040] that it imports.

A *base URL*

Null or a base URL used for resolving module specifiers[p1056]. When non-null, this will either be the URL from which the script was obtained, for external scripts, or the document base URL[p94] of the containing document, for inline scripts.

A **classic script** is a type of script[p1040] that has the following additional item:

A *muted errors* boolean

A boolean which, if true, means that error information will not be provided for errors in this script. This is used to mute errors for cross-origin scripts, since that can leak private information.

A **module script** is another type of script[p1040]. It has no additional items.

Module scripts[p1040] can be classified into three types:

- A module script[p1040] is a **JavaScript module script** if its record[p1040] is a Source Text Module Record.
- A module script[p1040] is a **CSS module script** if its record[p1040] is a Synthetic Module Record, and it was created via the create a CSS module script[p1049] algorithm. CSS module scripts represent a parsed CSS stylesheet.
- A module script[p1040] is a **JSON module script** if its record[p1040] is a Synthetic Module Record, and it was created via the

create a JSON module script[p1050] algorithm. JSON module scripts represent a parsed JSON document.

Note

As CSS stylesheets and JSON documents do not import dependent modules, and do not throw exceptions on evaluation, the fetch options[p1040] and base URL[p1040] of CSS module scripts[p1040] and JSON module scripts[p1040] and are always null.

The **active script** is determined by the following algorithm:

1. Let *record* be GetActiveScriptOrModule().
2. If *record* is null, return null.
3. Return *record*.[[HostDefined]].

Note

The active script[p1041] concept is so far only used by the `import()` feature, to determine the base URL[p1040] to use for resolving relative module specifiers.

8.1.4.2 Fetching scripts §[p1041]

This section introduces a number of algorithms for fetching scripts, taking various necessary inputs and resulting in classic[p1040] or module scripts[p1040].

Script fetch options is a struct with the following items:

cryptographic nonce
The cryptographic nonce metadata used for the initial fetch and for fetching any imported modules

integrity metadata
The integrity metadata used for the initial fetch

parser metadata
The parser metadata used for the initial fetch and for fetching any imported modules

credentials mode
The credentials mode used for the initial fetch (for module scripts[p1040]) and for fetching any imported modules (for both module scripts[p1040] and classic scripts[p1040])

referrer policy
The referrer policy used for the initial fetch and for fetching any imported modules

Note

This policy can mutate after a module script[p1040]'s response is received, to be the referrer policy parsed from the response, and used when fetching any module dependencies.

render-blocking
The boolean value of render-blocking used for the initial fetch and for fetching any imported modules. Unless otherwise stated, its value is false.

fetch priority
The priority used for the initial fetch

Note

Recall that via the `import()` feature, classic scripts[p1040] can import module scripts[p1040].

The **default classic script fetch options** are a script fetch options[p1041] whose cryptographic nonce[p1041] is the empty string, integrity metadata[p1041] is the empty string, parser metadata[p1041] is "`not-parser-inserted`", credentials mode[p1041] is "`same-origin`", referrer

policy[p1041] is the empty string, and fetch priority[p1041] is "`auto`".

Given a request *request* and a script fetch options[p1041] *options*, we define:

set up the classic script request

Set *request*'s cryptographic nonce metadata to *options*'s cryptographic nonce[p1041], its integrity metadata to *options*'s integrity metadata[p1041], its parser metadata to *options*'s parser metadata[p1041], its referrer policy to *options*'s referrer policy[p1041], its render-blocking to *options*'s render-blocking[p1041], and its priority to *options*'s fetch priority[p1041].

set up the module script request

Set *request*'s cryptographic nonce metadata to *options*'s cryptographic nonce[p1041], its integrity metadata to *options*'s integrity metadata[p1041], its parser metadata to *options*'s parser metadata[p1041], its credentials mode to *options*'s credentials mode[p1041], its referrer policy to *options*'s referrer policy[p1041], its render-blocking to *options*'s render-blocking[p1041], and its priority to *options*'s fetch priority[p1041].

For any given script fetch options[p1041] *options*, the **descendant script fetch options** are a new script fetch options[p1041] whose items all have the same values, except for the integrity metadata[p1041], which is instead the empty string, and the fetch priority[p1041], which is instead "`auto`".

Several of the below algorithms can be customized with a **perform the fetch hook** algorithm, which takes a request, a boolean *isTopLevel*[p1042], and a ***processCustomFetchResponse*** algorithm. It runs *processCustomFetchResponse*[p1042] with a response and either null (on failure) or a byte sequence containing the response body. ***isTopLevel*** will be true for all classic script[p1040] fetches, and for the initial fetch when fetching an external module script graph[p1044] or fetching a module worker script graph[p1045], but false for the fetches resulting from `import` statements encountered throughout the graph or from `import()` expressions.

By default, not supplying a perform the fetch hook[p1042] will cause the below algorithms to simply fetch the given request, with algorithm-specific customizations to the request and validations of the resulting response.

To layer your own customizations on top of these algorithm-specific ones, supply a perform the fetch hook[p1042] that modifies the given request, fetches it, and then performs specific validations of the resulting response (completing with a network error if the validations fail).

The hook can also be used to perform more subtle customizations, such as keeping a cache of responses and avoiding performing a fetch at all.

Note

Service Workers *is an example of a specification that runs these algorithms with its own options for the hook. [SW]*[p1417]

Now for the algorithms themselves.

To **fetch a classic script** given a *url*, a *settings object*, some *options*, a *CORS setting*, a *character encoding*, and an *onComplete* algorithm, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a classic script[p1040] (on success).

1. Let *request* be the result of creating a potential-CORS request[p96] given *url*, "`script`", and *CORS setting*.
2. Set *request*'s client to *settings object*.
3. Set *request*'s initiator type to "`script`".
4. Set up the classic script request[p1042] given *request* and *options*.
5. Fetch *request* with the following *processResponseConsumeBody* steps given response *response* and null, failure, or a byte sequence *bodyBytes*:

   Note

   response *can be either CORS-same-origin*[p95] *or CORS-cross-origin*[p95]*. This only affects how error reporting happens.*

   1. Set *response* to *response*'s unsafe response[p95].
   2. If either of the following conditions are met:
      - *bodyBytes* is null or failure; or

- *response*'s status is not an ok status,

then run *onComplete* given null, and abort these steps.

Note

For historical reasons, this algorithm does not include MIME type checking, unlike the other script-fetching algorithms in this section.

3. Let *potentialMIMETypeForEncoding* be the result of extracting a MIME type given *response*'s header list.
4. Set *character encoding* to the result of legacy extracting an encoding given *potentialMIMETypeForEncoding* and *character encoding*.

Note

This intentionally ignores the MIME type essence.

5. Let *source text* be the result of decoding *bodyBytes* to Unicode, using *character encoding* as the fallback encoding.

Note

The decode algorithm overrides character encoding *if the file contains a BOM.*

6. Let *muted errors* be true if *response* was CORS-cross-origin[p95], and false otherwise.
7. Let *script* be the result of creating a classic script[p1048] given *source text*, *settings object*, *response*'s URL, *options*, and *muted errors*.
8. Run *onComplete* given *script*.

To **fetch a classic worker script** given a *url*, a *fetch client settings object*, a *destination*, a *script settings object*, an *onComplete* algorithm, and an optional perform the fetch hook[p1042] *performFetch*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a classic script[p1040] (on success).

1. Let *request* be a new request whose URL is *url*, client is *fetch client settings object*, destination is *destination*, initiator type is "`other`", mode is "`same-origin`", credentials mode is "`same-origin`", parser metadata is "`not parser-inserted`", and whose use-URL-credentials flag is set.
2. If *performFetch* was given, run *performFetch* with *request*, true, and with *processResponseConsumeBody* as defined below.

   Otherwise, fetch *request* with *processResponseConsumeBody* set to *processResponseConsumeBody* as defined below.

   In both cases, let *processResponseConsumeBody* given response *response* and null, failure, or a byte sequence *bodyBytes* be the following algorithm:

   1. Set *response* to *response*'s unsafe response[p95].
   2. If either of the following conditions are met:

      - *bodyBytes* is null or failure; or
      - *response*'s status is not an ok status,

      then run *onComplete* given null, and abort these steps.

   3. If both of the following conditions are met:

      - *response*'s URL's scheme is an HTTP(S) scheme; and
      - the result of extracting a MIME type from *response*'s header list is not a JavaScript MIME type,

      then run *onComplete* given null, and abort these steps.

      Note

      Other fetch schemes are exempted from MIME type checking for historical web-compatibility reasons. We might be able to tighten this in the future; see issue #3255.

   4. Let *source text* be the result of UTF-8 decoding *bodyBytes*.
   5. Let *script* be the result of creating a classic script[p1048] using *source text*, *script settings object*, *response*'s URL, and

the default classic script fetch options[p1041].

6. Run *onComplete* given *script*.

To **fetch a classic worker-imported script** given a *url*, a *settings object*, and an optional perform the fetch hook[p1042] *performFetch*, run these steps. The algorithm will synchronously complete with a classic script[p1040] on success, or throw an exception on failure.

1. Let *response* be null.
2. Let *bodyBytes* be null.
3. Let *request* be a new request whose URL is *url*, client is *settings object*, destination is "`script`", initiator type is "`other`", parser metadata is "`not parser-inserted`", and whose use-URL-credentials flag is set.
4. If *performFetch* was given, run *performFetch* with *request*, *isTopLevel*, and with *processResponseConsumeBody* as defined below.

   Otherwise, fetch *request* with *processResponseConsumeBody* set to *processResponseConsumeBody* as defined below.

   In both cases, let *processResponseConsumeBody* given response *res* and null, failure, or a byte sequence *bb* be the following algorithm:

   1. Set *bodyBytes* to *bb*.
   2. Set *response* to *res*.
5. Pause[p1080] until *response* is not null.

   Note

   Unlike other algorithms in this section, the fetching process is synchronous here.

6. Set *response* to *response*'s unsafe response[p95].
7. If any of the following conditions are met:

   - *bodyBytes* is null or failure;
   - *response*'s status is not an ok status; or
   - the result of extracting a MIME type from *response*'s header list is not a JavaScript MIME type,

   then throw a "`NetworkError`" `DOMException`.
8. Let *source text* be the result of UTF-8 decoding *bodyBytes*.
9. Let *muted errors* be true if *response* was CORS-cross-origin[p95], and false otherwise.
10. Let *script* be the result of creating a classic script[p1048] given *source text*, *settings object*, *response*'s URL, the default classic script fetch options[p1041], and *muted errors*.
11. Return *script*.

To **fetch an external module script graph** given a *url*, a *settings object*, some *options*, and an *onComplete* algorithm, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a module script[p1040] (on success).

1. Disallow further import maps[p1061] given *settings object*.
2. Fetch a single module script[p1047] given *url*, *settings object*, "`script`", *options*, *settings object*, "`client`", true, and with the following steps given *result*:

   1. If *result* is null, run *onComplete* given null, and abort these steps.
   2. Fetch the descendants of and link[p1046] *result* given "`script`" and *onComplete*.

To **fetch a modulepreload module script graph** given a *url*, a *destination*, a *settings object*, some *options*, and an *onComplete* algorithm, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a module script[p1040] (on success).

1. Disallow further import maps[p1061] given *settings object*.
2. Fetch a single module script[p1047] given *url*, *settings object*, *destination*, *options*, *settings object*, "`client`", true, and with the

following steps given *result*:

1. Run *onComplete* given *result*.
2. If *result* is not null, optionally fetch the descendants of and link[p1046] *result* given *destination* and an empty algorithm.

> **Note**
> *Generally, performing this step will be beneficial for performance, as it allows pre-loading the modules that will invariably be requested later, via algorithms such as fetch an external module script graph[p1044] that fetch the entire graph. However, user agents might wish to skip them in bandwidth-constrained situations, or situations where the relevant fetches are already in flight.*

To **fetch an inline module script graph** given a *source text*, *base URL*, *settings object*, *options*, and an *onComplete* algorithm, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a module script[p1040] (on success).

1. Disallow further import maps[p1061] given *settings object*.
2. Let *script* be the result of creating a JavaScript module script[p1049] using *source text*, *settings object*, *base URL*, and *options*.
3. If *script* is null, run *onComplete* given null, and return.
4. Fetch the descendants of and link[p1046] *script*, given "`script`" and *onComplete*.

To **fetch a module worker script graph** given a *url*, a *fetch client settings object*, a *destination*, a *credentials mode*, a *module map settings object*, and an *onComplete* algorithm, fetch a worklet/module worker script graph[p1046] given *url*, *fetch client settings object*, *destination*, *credentials mode*, *module map settings object*, and *onComplete*.

To **fetch a worklet script graph** given a *url*, a *fetch client settings object*, a *destination*, a *credentials mode*, a *module map settings object*, a *moduleResponsesMap*, and an *onComplete* algorithm, fetch a worklet/module worker script graph[p1046] given *url*, *fetch client settings object*, *destination*, *credentials mode*, *module map settings object*, *onComplete*, and the following perform the fetch hook[p1042] given *request* and *processCustomFetchResponse*[p1042]:

1. Let *requestURL* be *request*'s URL.
2. If *moduleResponsesMap*[*requestURL*] is "`fetching`", wait in parallel[p43] until that entry's value changes, then queue a task[p1072] on the networking task source[p1081] to proceed with running the following steps.
3. If *moduleResponsesMap*[*requestURL*] exists, then:
    1. Let *cached* be *moduleResponsesMap*[*requestURL*].
    2. Run *processCustomFetchResponse* with *cached*[0] and *cached*[1].
    3. Return.
4. Set *moduleResponsesMap*[*requestURL*] to "`fetching`".
5. Fetch *request*, with *processResponseConsumeBody* set to the following steps given response *response* and null, failure, or a byte sequence *bodyBytes*:
    1. Set *moduleResponsesMap*[*requestURL*] to (*response*, *bodyBytes*).
    2. Run *processCustomFetchResponse* with *response* and *bodyBytes*.

The following algorithms are meant for internal use by this specification only as part of fetching an external module script graph[p1044] or other similar concepts above, and should not be used directly by other specifications.

This diagram illustrates how these algorithms relate to the ones above, as well as to each other:

To **fetch a worklet/module worker script graph** given a *url*, a *fetch client settings object*, a *destination*, a *credentials mode*, a *module map settings object*, an *onComplete* algorithm, and an optional perform the fetch hook[p1042] *performFetch*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a module script[p1040] (on success).

1. Let *options* be a script fetch options[p1041] whose cryptographic nonce[p1041] is the empty string, integrity metadata[p1041] is the empty string, parser metadata[p1041] is "`not-parser-inserted`", credentials mode[p1041] is *credentials mode*, referrer policy[p1041] is the empty string, and fetch priority[p1041] is "`auto`".

2. Fetch a single module script[p1047] given *url*, *fetch client settings object*, *destination*, *options*, *module map settings object*, "`client`", true, and *onSingleFetchComplete* as defined below. If *performFetch* was given, pass it along as well.

   onSingleFetchComplete given *result* is the following algorithm:

   1. If *result* is null, run *onComplete* given null, and abort these steps.

   2. Fetch the descendants of and link[p1046] *result* given *destination* and *onComplete*. If *performFetch* was given, pass it along as well.

To **fetch the descendants of and link a module script** *module script*, given a *destination*, an *onComplete* algorithm, and an optional perform the fetch hook[p1042] *performFetch*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a module script[p1040] (on success).

1. Let *record* be *module script*'s record[p1040].

2. If *record* is null, then:

   1. Set *module script*'s error to rethrow[p1040] to *module script*'s parse error[p1212].

   2. Run *onComplete* given *module script*.

   3. Return.

3. Let *state* be Record { [[ParseError]]: null, [[Destination]]: *destination*, [[PerformFetch]]: null }.

4. If *performFetch* was given, set *state*.[[PerformFetch]] to *performFetch*.

5. Let *loadingPromise* be *record*.LoadRequestedModules(*state*).

   Note
   This step will recursively load all the module transitive dependencies.

6. Upon fulfillment of *loadingPromise*, run the following steps:

   1. Perform *record*.Link().

      Note
      This step will recursively call Link on all of the module's unlinked dependencies.

      If this throws an exception, catch it, and set *module script*'s error to rethrow[p1040] to that exception.

   2. Run *onComplete* given *module script*.

7. Upon rejection of *loadingPromise*, run the following steps:

   1. If *state*.[[ParseError]] is not null, set *module script*'s error to rethrow[p1040] to *state*.[[ParseError]] and run *onComplete* given *module script*.

   2. Otherwise, run *onComplete* given null.

Note

state.*[[ParseError]] is null when* loadingPromise *is rejected due to a loading error.*

To **fetch a single module script**, given a *url*, a *fetch client settings object*, a *destination*, some *options*, a *module map settings object*, a *referrer*, an optional *moduleRequest*, a boolean *isTopLevel*[p1042], an *onComplete* algorithm, and an optional perform the fetch hook[p1042] *performFetch*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a module script[p1040] (on success).

1. Let *moduleType* be "`javascript`".
2. If *moduleRequest* was given, then set *moduleType* to the result of running the module type from module request[p1050] steps given *moduleRequest*.
3. Assert: the result of running the module type allowed[p1050] steps given *moduleType* and *module map settings object* is true. Otherwise we would not have reached this point because a failure would have been raised when inspecting *moduleRequest*.[[Attributes]] in create a JavaScript module script[p1049] or fetch a single imported module script[p1048].
4. Let *moduleMap* be *module map settings object*'s module map[p1032].
5. If *moduleMap*[(*url*, *moduleType*)] is "`fetching`", wait in parallel[p43] until that entry's value changes, then queue a task[p1072] on the networking task source[p1081] to proceed with running the following steps.
6. If *moduleMap*[(*url*, *moduleType*)] exists, run *onComplete* given *moduleMap*[(*url*, *moduleType*)], and return.
7. Set *moduleMap*[(*url*, *moduleType*)] to "`fetching`".
8. Let *request* be a new request whose URL is *url*, destination is *destination*, mode is "`cors`", referrer is *referrer*, and client is *fetch client settings object*.
9. If *destination* is "`worker`", "`sharedworker`", or "`serviceworker`", and the *top-level module fetch* flag is set, then set *request*'s mode to "`same-origin`".
10. Set *request*'s initiator type to "`script`".
11. Set up the module script request[p1042] given *request* and *options*.
12. If *performFetch* was given, run *performFetch* with *request*, *isTopLevel*, and with *processResponseConsumeBody* as defined below.

    Otherwise, fetch *request* with *processResponseConsumeBody* set to *processResponseConsumeBody* as defined below.

    In both cases, let *processResponseConsumeBody* given response *response* and null, failure, or a byte sequence *bodyBytes* be the following algorithm:

    Note

    response *is always CORS-same-origin*[p95].

    1. If either of the following conditions are met:
       - *bodyBytes* is null or failure; or
       - *response*'s status is not an ok status,

       then set *moduleMap*[(*url*, *moduleType*)] to null, run *onComplete* given null, and abort these steps.
    2. Let *source text* be the result of UTF-8 decoding *bodyBytes*.
    3. Let *MIME type* be the result of extracting a MIME type from *response*'s header list.
    4. Let *module script* be null.
    5. Let *referrerPolicy* be the result of parsing the `Referrer-Policy` header given *response*. [REFERRERPOLICY][p1416]
    6. If *referrerPolicy* is not the empty string, set *options*'s referrer policy[p1041] to *referrerPolicy*.
    7. If *MIME type* is a JavaScript MIME type and *moduleType* is "`javascript`", then set *module script* to the result of creating a JavaScript module script[p1049] given *source text*, *module map settings object*, *response*'s URL, and *options*.

8. If the MIME type essence of *MIME type* is "text/css[p1409]" and *moduleType* is "`css`", then set *module script* to the result of creating a CSS module script[p1049] given *source text* and *module map settings object*.

9. If *MIME type essence* is a JSON MIME type and *moduleType* is "`json`", then set *module script* to the result of creating a JSON module script[p1050] given *source text* and *module map settings object*.

10. Set *moduleMap*[(*url*, *moduleType*)] to *module script*, and run *onComplete* given *module script*.

> **Note**
> *It is intentional that the module map[p1068] is keyed by the request URL, whereas the base URL[p1040] for the module script[p1040] is set to the response URL. The former is used to deduplicate fetches, while the latter is used for URL resolution.*

To **fetch a single imported module script**, given a *url*, a *settings object*, a *destination*, some *options*, a *referrer*, a *moduleRequest*, an *onComplete* algorithm, and an optional perform the fetch hook[p1042] *performFetch*, run these steps. *onComplete* must be an algorithm accepting null (on failure) or a module script[p1040] (on success).

1. Assert: *moduleRequest*.[[Attributes]] does not contain any Record *entry* such that *entry*.[[Key]] is not "`type`", because we only asked for "`type`" attributes in HostGetSupportedImportAttributes[p1069].

2. Let *moduleType* be the result of running the module type from module request[p1050] steps given *moduleRequest*.

3. If the result of running the module type allowed[p1050] steps given *moduleType* and *settings object* is false, then run *onComplete* given null, and return.

4. Fetch a single module script[p1047] given *url*, *settings object*, *destination*, *options*, *settings object*, *referrer*, *moduleRequest*, false, and *onComplete*. If *performFetch* was given, pass it along as well.

8.1.4.3 Creating scripts §[p1048]

To **create a classic script**, given a string *source*, an environment settings object[p1032] *settings*, a URL *baseURL*, some script fetch options[p1041] *options*, and an optional boolean *mutedErrors* (default false):

1. If *mutedErrors* is true, then set *baseURL* to `about:blank`[p53].

> **Note**
> *When* mutedErrors *is true,* baseURL *is the script's CORS-cross-origin[p95] response's url, which shouldn't be exposed to JavaScript. Therefore,* baseURL *is sanitized here.*

2. If scripting is disabled[p1039] for *settings*, then set *source* to the empty string.

3. Let *script* be a new classic script[p1040] that this algorithm will subsequently initialize.

4. Set *script*'s settings object[p1040] to *settings*.

5. Set *script*'s base URL[p1040] to *baseURL*.

6. Set *script*'s fetch options[p1040] to *options*.

7. Set *script*'s muted errors[p1040] to *mutedErrors*.

8. Set *script*'s parse error[p1040] and error to rethrow[p1040] to null.

9. Let *result* be ParseScript(*source*, *settings*'s realm[p1033], *script*).

> **Note**
> *Passing* script *as the last parameter here ensures* result.*[[HostDefined]] will be* script.

10. If *result* is a list of errors, then:

    1. Set *script*'s parse error[p1040] and its error to rethrow[p1040] to *result*[0].

    2. Return *script*.

11. Set *script*'s record[p1040] to *result*.

12. Return *script*.

To **create a JavaScript module script**, given a string *source*, an environment settings object[p1032] *settings*, a URL *baseURL*, and some script fetch options[p1041] *options*:

1. If scripting is disabled[p1039] for *settings*, then set *source* to the empty string.
2. Let *script* be a new module script[p1040] that this algorithm will subsequently initialize.
3. Set *script*'s settings object[p1040] to *settings*.
4. Set *script*'s base URL[p1040] to *baseURL*.
5. Set *script*'s fetch options[p1040] to *options*.
6. Set *script*'s parse error[p1040] and error to rethrow[p1040] to null.
7. Let *result* be ParseModule(*source*, *settings*'s realm[p1033], *script*).

   Note

   Passing script *as the last parameter here ensures* result.*[[HostDefined]] will be* script.

8. If *result* is a list of errors, then:
   1. Set *script*'s parse error[p1040] to *result*[0].
   2. Return *script*.
9. Assert: *requested*.[[Attributes]] does not contain any Record *entry* such that *entry*.[[Key]] is not "`type`", because we only asked for "`type`" attributes in HostGetSupportedImportAttributes[p1069].
10. For each ModuleRequest record *requested* of *result*.[[RequestedModules]]:
    1. Let *url* be the result of resolving a module specifier[p1056] given *script* and *requested*.[[Specifier]], catching any exceptions.
    2. If the previous step threw an exception, then:
       1. Set *script*'s parse error[p1040] to that exception.
       2. Return *script*.
    3. Let *moduleType* be the result of running the module type from module request[p1050] steps given *requested*.
    4. If the result of running the module type allowed[p1050] steps given *moduleType* and *settings* is false, then:
       1. Let *error* be a new `TypeError` exception.
       2. Set *script*'s parse error[p1040] to *error*.
       3. Return *script*.

    Note

    This step is essentially validating all of the requested module specifiers and type attributes. We treat a module with unresolvable module specifiers or unsupported type attributes the same as one that cannot be parsed; in both cases, a syntactic issue makes it impossible to ever contemplate linking the module later.

11. Set *script*'s record[p1040] to *result*.
12. Return *script*.

To **create a CSS module script**, given a string *source* and an environment settings object[p1032] *settings*:

1. Let *script* be a new module script[p1040] that this algorithm will subsequently initialize.
2. Set *script*'s settings object[p1040] to *settings*.
3. Set *script*'s base URL[p1040] and fetch options[p1040] to null.
4. Set *script*'s parse error[p1040] and error to rethrow[p1040] to null.

5. Let *sheet* be the result of running the steps to create a constructed CSSStyleSheet with an empty dictionary as the argument.

6. Run the steps to synchronously replace the rules of a CSSStyleSheet on *sheet* given *source*.

   If this throws an exception, catch it, and set *script*'s parse error[p1040] to that exception, and return *script*.

   > **Note**
   > *The steps to synchronously replace the rules of a CSSStyleSheet will throw if* source *contains any* `@import` *rules. This is by-design for now because there is not yet an agreement on how to handle these for CSS module scripts; therefore they are blocked altogether until a consensus is reached.*

7. Set *script*'s record[p1040] to the result of CreateDefaultExportSyntheticModule(*sheet*).

8. Return *script*.

To **create a JSON module script**, given a string *source* and an environment settings object[p1032] *settings*:

1. Let *script* be a new module script[p1040] that this algorithm will subsequently initialize.

2. Set *script*'s settings object[p1040] to *settings*.

3. Set *script*'s base URL[p1040] and fetch options[p1040] to null.

4. Set *script*'s parse error[p1040] and error to rethrow[p1040] to null.

5. Let *result* be ParseJSONModule(*source*).

   If this throws an exception, catch it, and set *script*'s parse error[p1040] to that exception, and return *script*.

6. Set *script*'s record[p1040] to *result*.

7. Return *script*.

The **module type from module request** steps, given a ModuleRequest Record *moduleRequest*, are as follows:

1. Let *moduleType* be "`javascript`".

2. If *moduleRequest*.[[Attributes]] has a Record *entry* such that *entry*.[[Key]] is "`type`", then:

   1. If *entry*.[[Value]] is "`javascript`", then set *moduleType* to null.

      > **Note**
      > *This specification uses the* "`javascript`" *module type internally for JavaScript module scripts[p1040], so this step is needed to prevent modules from being imported using a* "`javascript`" *type attribute (a null* moduleType *will cause the module type allowed[p1050] check to fail).*

   2. Otherwise, set *moduleType* to *entry*.[[Value]].

3. Return *moduleType*.

The **module type allowed** steps, given a string *moduleType* and an environment settings object[p1032] *settings*, are as follows:

1. If *moduleType* is not "`javascript`", "`css`", or "`json`", then return false.

2. If *moduleType* is "`css`" and the CSSStyleSheet interface is not exposed in *settings*'s realm[p1033], then return false.

3. Return true.

8.1.4.4 Calling scripts §[p1050]

To **run a classic script** given a classic script[p1040] *script* and an optional boolean *rethrow errors* (default false):

1. Let *settings* be the settings object[p1040] of *script*.

2. Check if we can run script[p1052] with *settings*. If this returns "do not run" then return NormalCompletion(empty).

3. Prepare to run script[p1052] given *settings*.
4. Let *evaluationStatus* be null.
5. If *script*'s error to rethrow[p1040] is not null, then set *evaluationStatus* to Completion { [[Type]]: throw, [[Value]]: *script*'s error to rethrow[p1040], [[Target]]: empty }.
6. Otherwise, set *evaluationStatus* to ScriptEvaluation(*script*'s record[p1040]).

   If ScriptEvaluation does not complete because the user agent has aborted the running script[p1052], leave *evaluationStatus* as null.
7. If *evaluationStatus* is an abrupt completion, then:
   1. If *rethrow errors* is true and *script*'s muted errors[p1040] is false, then:
      1. Clean up after running script[p1052] with *settings*.
      2. Rethrow *evaluationStatus*.[[Value]].
   2. If *rethrow errors* is true and *script*'s muted errors[p1040] is true, then:
      1. Clean up after running script[p1052] with *settings*.
      2. Throw a "`NetworkError`" `DOMException`.
   3. Otherwise, *rethrow errors* is false. Perform the following steps:
      1. Report the exception[p1053] given by *evaluationStatus*.[[Value]] for *script*.
      2. Clean up after running script[p1052] with *settings*.
      3. Return *evaluationStatus*.
8. Clean up after running script[p1052] with *settings*.
9. If *evaluationStatus* is a normal completion, then return *evaluationStatus*.
10. If we've reached this point, *evaluationStatus* was left as null because the script was aborted prematurely[p1052] during evaluation. Return Completion { [[Type]]: throw, [[Value]]: a new "`QuotaExceededError`" `DOMException`, [[Target]]: empty }.

To **run a module script** given a module script[p1040] *script* and an optional boolean *preventErrorReporting* (default false):

1. Let *settings* be the settings object[p1040] of *script*.
2. Check if we can run script[p1052] with *settings*. If this returns "do not run", then return a promise resolved with with undefined.
3. Prepare to run script[p1052] given *settings*.
4. Let *evaluationPromise* be null.
5. If *script*'s error to rethrow[p1040] is not null, then set *evaluationPromise* to a promise rejected with *script*'s error to rethrow[p1040].
6. Otherwise:
   1. Let *record* be *script*'s record[p1040].
   2. Set *evaluationPromise* to *record*.Evaluate().

      Note
      This step will recursively evaluate all of the module's dependencies.

      If Evaluate fails to complete as a result of the user agent aborting the running script[p1052], then set *evaluationPromise* to a promise rejected with a new "`QuotaExceededError`" `DOMException`.
7. If *preventErrorReporting* is false, then upon rejection of *evaluationPromise* with *reason*, report the exception[p1053] given by *reason* for *script*.
8. Clean up after running script[p1052] with *settings*.
9. Return *evaluationPromise*.

The steps to **check if we can run script** with an environment settings object[p1032] *settings* are as follows. They return either "run" or "do not run".

1. If the global object[p1033] specified by *settings* is a `Window`[p892] object whose `Document`[p127] object is not fully active[p966], then return "do not run".
2. If scripting is disabled[p1039] for *settings*, then return "do not run".
3. Return "run".

The steps to **prepare to run script** with an environment settings object[p1032] *settings* are as follows:

1. Push *settings*'s realm execution context[p1032] onto the JavaScript execution context stack; it is now the running JavaScript execution context.
2. Add *settings* to the currently running task[p1071]'s script evaluation environment settings object set[p1072].

The steps to **clean up after running script** with an environment settings object[p1032] *settings* are as follows:

1. Assert: *settings*'s realm execution context[p1032] is the running JavaScript execution context.
2. Remove *settings*'s realm execution context[p1032] from the JavaScript execution context stack.
3. If the JavaScript execution context stack is now empty, perform a microtask checkpoint[p1077]. (If this runs scripts, these algorithms will be invoked reentrantly.)

Note

These algorithms are not invoked by one script directly calling another, but they can be invoked reentrantly in an indirect manner, e.g. if a script dispatches an event which has event listeners registered.

The **running script** is the script[p1040] in the [[HostDefined]] field in the ScriptOrModule component of the running JavaScript execution context.

8.1.4.5 Killing scripts §[p1052]

Although the JavaScript specification does not account for this possibility, it's sometimes necessary to **abort a running script**. This causes any ScriptEvaluation or Source Text Module Record Evaluate invocations to cease immediately, emptying the JavaScript execution context stack without triggering any of the normal mechanisms like `finally` blocks. [JAVASCRIPT][p1414]

User agents may impose resource limitations on scripts, for example CPU quotas, memory limits, total execution time limits, or bandwidth limitations. When a script exceeds a limit, the user agent may either throw a `"QuotaExceededError"` `DOMException`, abort the script[p1052] without an exception, prompt the user, or throttle script execution.

Example

For example, the following script never terminates. A user agent could, after waiting for a few seconds, prompt the user to either terminate the script or let it continue.

```
<script>
 while (true) { /* loop */ }
</script>
```

User agents are encouraged to allow users to disable scripting whenever the user is prompted either by a script (e.g. using the `window.alert()`[p1106] API) or because of a script's actions (e.g. because it has exceeded a time limit).

If scripting is disabled while a script is executing, the script should be terminated immediately.

User agents may allow users to specifically disable scripts just for the purposes of closing a browsing context[p961].

Example

For example, the prompt mentioned in the example above could also offer the user with a mechanism to just close the page

entirely, without running any unload[p1407] event handlers.

8.1.4.6 Runtime script errors §[p1053]

For web developers (non-normative)

self.reportError[p1054](e)

Dispatches an error[p1406] event at the global object for the given value *e*, in the same fashion as an unhandled exception.

When the user agent is required to **report an error** for a particular script[p1040] *script* with a particular position *line*:*col*, using a particular target *target*, it must run these steps, after which the error is either ***handled*** or ***not handled***:

1. If *target* is in error reporting mode[p1053], then return; the error is *not handled*[p1053].
2. Let *target* be **in error reporting mode**.
3. Let *message* be an implementation-defined string describing the error in a helpful manner.
4. Let *errorValue* be the value that represents the error: in the case of an uncaught exception, that would be the value that was thrown; in the case of a JavaScript error that would be an `Error` object. If there is no corresponding value, then the null value must be used instead.
5. Let *urlString* be the result of applying the URL serializer to the URL record that corresponds to the resource from which *script* was obtained.

   Note

   The resource containing the script will typically be the file from which the Document[p127] *was parsed, e.g. for inline* script[p638] *elements or event handler content attributes*[p1084]*; or the JavaScript file that the script was in, for external scripts. Even for dynamically-generated scripts, user agents are strongly encouraged to attempt to keep track of the original source of a script. For example, if an external script uses the* document.write()[p1099] *API to insert an inline* script[p638] *element during parsing, the URL of the resource containing the script would ideally be reported as being the external script, and the line number might ideally be reported as the line with the* document.write()[p1099] *call or where the string passed to that call was first constructed. Naturally, implementing this can be somewhat non-trivial.*

   Note

   User agents are similarly encouraged to keep careful track of the original line numbers, even in the face of document.write()[p1099] *calls mutating the document as it is parsed, or event handler content attributes*[p1084] *spanning multiple lines.*

6. If *script* is a classic script[p1040] and *script*'s muted errors[p1040] is true, then set *message* to "`Script error.`", *urlString* to the empty string, *line* and *col* to 0, and *errorValue* to null.
7. Let *notHandled* be true.
8. If *target* implements EventTarget, then set *notHandled* to the result of firing an event named error[p1406] at *target*, using ErrorEvent[p1054], with the cancelable attribute initialized to true, the message[p1054] attribute initialized to *message*, the filename[p1054] attribute initialized to *urlString*, the lineno[p1054] attribute initialized to *line*, the colno[p1054] attribute initialized to *col*, and the error[p1054] attribute initialized to *errorValue*.
9. Let *target* no longer be in error reporting mode[p1053].
10. If *notHandled* is false, then the error is *handled*[p1053]. Otherwise, the error is *not handled*[p1053].

    Note

    Returning true in an event handler cancels the event per the event handler processing algorithm[p1086].

When the user agent is to **report an exception** *E*, the user agent must report the error[p1053] for the relevant script[p1040], with the problematic position (line number and column number) in the resource containing the script, using the global object[p1033] specified by the script's settings object[p1040] as the target. If the error is still *not handled*[p1053] after this, then the error may be reported to a developer console.

The existence of both report an error[p1053] and report an exception[p1053] is confusing, and both algorithms have known problems. You can track future cleanup in this area in issue #958.

The **reportError(e)** method steps are to report the exception[p1053] *e*.

The ErrorEvent[p1054] interface is defined as follows:

IDL
```
[Exposed=*]
interface ErrorEvent : Event {
  constructor(DOMString type, optional ErrorEventInit eventInitDict = {});

  readonly attribute DOMString message;
  readonly attribute USVString filename;
  readonly attribute unsigned long lineno;
  readonly attribute unsigned long colno;
  readonly attribute any error;
};

dictionary ErrorEventInit : EventInit {
  DOMString message = "";
  USVString filename = "";
  unsigned long lineno = 0;
  unsigned long colno = 0;
  any error;
};
```

The **message** attribute must return the value it was initialized to. It represents the error message.

The **filename** attribute must return the value it was initialized to. It represents the URL of the script in which the error originally occurred.

The **lineno** attribute must return the value it was initialized to. It represents the line number where the error occurred in the script.

The **colno** attribute must return the value it was initialized to. It represents the column number where the error occurred in the script.

The **error** attribute must return the value it was initialized to. It must initially be initialized to undefined. Where appropriate, it is set to the object representing the error (e.g., the exception object in the case of an uncaught exception).

8.1.4.7 Unhandled promise rejections §p1054

In addition to synchronous runtime script errors[p1053], scripts may experience asynchronous promise rejections, tracked via the unhandledrejection[p1407] and rejectionhandled[p1407] events. Tracking these rejections is done via the HostPromiseRejectionTracker[p1064] abstract operation, but reporting them is defined here.

To **notify about rejected promises** on a given environment settings object[p1032] *settings object*:

1. Let *list* be a copy of *settings object*'s about-to-be-notified rejected promises list[p1032].
2. If *list* is empty, return.
3. Clear *settings object*'s about-to-be-notified rejected promises list[p1032].
4. Let *global* be *settings object*'s global object[p1033].
5. Queue a global task[p1073] on the DOM manipulation task source[p1080] given *global* to run the following substep:
    1. For each promise *p* in *list*:
        1. If *p*'s [[PromiseIsHandled]] internal slot is true, continue to the next iteration of the loop.
        2. Let *notHandled* be the result of firing an event named unhandledrejection[p1407] at *global*, using PromiseRejectionEvent[p1055], with the cancelable attribute initialized to true, the promise[p1055] attribute

initialized to *p*, and the reason[p1055] attribute initialized to the value of *p*'s [[PromiseResult]] internal slot.

3. If *notHandled* is false, then the promise rejection is *handled*[p1055]. Otherwise, the promise rejection is *not handled*[p1055].

4. If *p*'s [[PromiseIsHandled]] internal slot is false, add *p* to *settings object*'s outstanding rejected promises weak set[p1032].

This algorithm results in promise rejections being marked as ***handled*** or ***not handled***. These concepts parallel *handled*[p1053] and *not handled*[p1053] script errors. If a rejection is still *not handled*[p1055] after this, then the rejection may be reported to a developer console.

The PromiseRejectionEvent[p1055] interface is defined as follows:

IDL
```
[Exposed=*]
interface PromiseRejectionEvent : Event {
  constructor(DOMString type, PromiseRejectionEventInit eventInitDict);

  readonly attribute Promise<any> promise;
  readonly attribute any reason;
};

dictionary PromiseRejectionEventInit : EventInit {
  required Promise<any> promise;
  any reason;
};
```

The **promise** attribute must return the value it was initialized to. It represents the promise which this notification is about.

The **reason** attribute must return the value it was initialized to. It represents the rejection reason for the promise.

8.1.4.8 Import map parse results §[p1055]

An **import map parse result** is a struct that is similar to a script[p1040], and also can be stored in a script[p638] element's result[p645], but is not counted as a script[p1040] for other purposes. It has the following items:

An *import map*
An import map[p1060] or null.

An *error to rethrow*
A JavaScript value representing an error that will prevent using this import map, when non-null.

To **create an import map parse result** given a string *input* and a URL *baseURL*:

1. Let *result* be an import map parse result[p1055] whose import map[p1055] is null and whose error to rethrow[p1055] is null.

2. Parse an import map string[p1061] given *input* and *baseURL*, catching any exceptions. If this threw an exception, then set *result*'s error to rethrow[p1055] to that exception. Otherwise, set *result*'s import map[p1055] to the return value.

3. Return *result*.

To **register an import map** given a Window[p892] *global* and an import map parse result[p1055] *result*:

1. If *result*'s error to rethrow[p1055] is not null, then report the exception[p1053] given by *result*'s error to rethrow[p1055] and return.

2. Assert: *global*'s import map[p1061] is an empty import map[p1061].

3. Set *global*'s import map[p1061] to *result*'s import map[p1055].

8.1.5 Module specifier resolution §p1056

8.1.5.1 The resolution algorithm §p1056

The resolve a module specifier[p1056] algorithm is the primary entry point for converting module specifier strings into URLs. When no import maps[p1060] are involved, it is relatively straightforward, and reduces to resolving a URL-like module specifier[p1057].

When there is a non-empty import map[p1060] present, the behavior is more complex. It checks candidate entries from all applicable module specifier maps[p1061], from most-specific to least-specific scopes[p1061] (falling back to the top-level unscoped imports[p1060]), and from most-specific to least-specific prefixes. For each candidate, the resolve an imports match[p1057] algorithm will give on the following results:

- Successful resolution of the specifier to a URL. Then the resolve a module specifier[p1056] algorithm will return that URL.
- Throwing an exception. Then the resolve a module specifier[p1056] algorithm will rethrow that exception, without any further fallbacks.
- Failing to resolve, without an error. In this case the outer resolve a module specifier[p1056] algorithm will move on to the next candidate.

In the end, if no successful resolution is found via any of the candidate module specifier maps[p1061], resolve a module specifier[p1056] will throw an exception. Thus the result is always either a URL or a thrown exception.

To **resolve a module specifier** given a script[p638]-or-null *referringScript* and a string *specifier*:

1. Let *settingsObject* and *baseURL* be null.
2. If *referringScript* is not null, then:
    1. Set *settingsObject* to *referringScript*'s settings object[p1040].
    2. Set *baseURL* to *referringScript*'s base URL[p1040].
3. Otherwise:
    1. Assert: there is a current settings object[p1038].
    2. Set *settingsObject* to the current settings object[p1038].
    3. Set *baseURL* to *settingsObject*'s API base URL[p1032].
4. Let *importMap* be an empty import map[p1061].
5. If *settingsObject*'s global object[p1033] implements `Window`[p892], then set *importMap* to *settingsObject*'s global object[p1033]'s import map[p1061].
6. Let *baseURLString* be *baseURL*, serialized.
7. Let *asURL* be the result of resolving a URL-like module specifier[p1057] given *specifier* and *baseURL*.
8. Let *normalizedSpecifier* be the serialization of *asURL*, if *asURL* is non-null; otherwise, *specifier*.
9. For each *scopePrefix* → *scopeImports* of *importMap*'s scopes[p1061]:
    1. If *scopePrefix* is *baseURLString*, or if *scopePrefix* ends with U+002F (/) and *scopePrefix* is a code unit prefix of *baseURLString*, then:
        1. Let *scopeImportsMatch* be the result of resolving an imports match[p1057] given *normalizedSpecifier*, *asURL*, and *scopeImports*.
        2. If *scopeImportsMatch* is not null, then return *scopeImportsMatch*.
10. Let *topLevelImportsMatch* be the result of resolving an imports match[p1057] given *normalizedSpecifier*, *asURL*, and *importMap*'s imports[p1060].
11. If *topLevelImportsMatch* is not null, then return *topLevelImportsMatch*.

Note

12. *At this point,* specifier *wasn't remapped to anything by* importMap*, but it might have been able to be turned into a URL.*

If *asURL* is not null, then return *asURL*.

13. Throw a `TypeError` indicating that *specifier* was a bare specifier, but was not remapped to anything by *importMap*.

To **resolve an imports match**, given a string *normalizedSpecifier*, a URL-or-null *asURL*, and a module specifier map[p1061] *specifierMap*:

1. For each *specifierKey* → *resolutionResult* of *specifierMap*:
    1. If *specifierKey* is *normalizedSpecifier*, then:
        1. If *resolutionResult* is null, then throw a `TypeError` indicating that resolution of *specifierKey* was blocked by a null entry.

            Note
            This will terminate the entire resolve a module specifier[p1056] algorithm, without any further fallbacks.

        2. Assert: *resolutionResult* is a URL.
        3. Return *resolutionResult*.
    2. If all of the following are true:
        - *specifierKey* ends with U+002F (/);
        - *specifierKey* is a code unit prefix of *normalizedSpecifier*; and
        - either *asURL* is null, or *asURL* is special,

        then:
        1. If *resolutionResult* is null, then throw a `TypeError` indicating that the resolution of *specifierKey* was blocked by a null entry.

            Note
            This will terminate the entire resolve a module specifier[p1056] algorithm, without any further fallbacks.

        2. Assert: *resolutionResult* is a URL.
        3. Let *afterPrefix* be the portion of *normalizedSpecifier* after the initial *specifierKey* prefix.
        4. Assert: *resolutionResult*, serialized, ends with U+002F (/), as enforced during parsing[p1061].
        5. Let *url* be the result of URL parsing *afterPrefix* with *resolutionResult*.
        6. If *url* is failure, then throw a `TypeError` indicating that resolution of *normalizedSpecifier* was blocked since the *afterPrefix* portion could not be URL-parsed relative to the *resolutionResult* mapped to by the *specifierKey* prefix.

            Note
            This will terminate the entire resolve a module specifier[p1056] algorithm, without any further fallbacks.

        7. Assert: *url* is a URL.
        8. If the serialization of *resolutionResult* is not a code unit prefix of the serialization of *url*, then throw a `TypeError` indicating that the resolution of *normalizedSpecifier* was blocked due to it backtracking above its prefix *specifierKey*.

            Note
            This will terminate the entire resolve a module specifier[p1056] algorithm, without any further fallbacks.

        9. Return *url*.
2. Return null.

Note
The resolve a module specifier[p1056] algorithm will fall back to a less-specific scope, or to `"imports"`*, if possible.*

To **resolve a URL-like module specifier**, given a string *specifier* and a URL *baseURL*:

1. If *specifier* starts with `"/"`, `"./"`, or `"../"`, then:

1. Let *url* be the result of URL parsing *specifier* with *baseURL*.
2. If *url* is failure, then return null.

   Example

   One way this could happen is if *specifier* is "`../foo`" and *baseURL* is a `data:` URL.

3. Return *url*.

Note

This includes cases where specifier *starts with* "`//`", *i.e., scheme-relative URLs. Thus,* url *might end up with a different host than* baseURL.

2. Let *url* be the result of URL parsing *specifier* (with no base URL).
3. If *url* is failure, then return null.
4. Return *url*.

8.1.5.2 Import maps §[p10 58]

An import map[p1060] allows control over module specifier resolution. Import maps are delivered via inline `script`[p638] elements with their `type`[p639] attribute set to "`importmap`", and with their child text content containing a JSON representation of the import map.

Only one import map is processed per `Document`[p127]. After the first import map is seen, others will be ignored, with their corresponding `script`[p638] elements generating `error`[p1406] events. Similarly, once any modules have been imported, e.g., via `import()` expressions or `script`[p638] elements with their `type`[p639] attribute set to "`module`", further import maps will be ignored.

Note

These restrictions, as well as the lack of support for external import maps, are in place to keep the initial version of the feature simple. They might be lifted over time as implementer bandwidth allows.

Example

The simplest use of import maps is to globally remap a bare module specifier:

```
{
  "imports": {
    "moment": "/node_modules/moment/src/moment.js"
  }
}
```

This enables statements like `import moment from "moment";` to work, fetching and evaluating the JavaScript module at the `/node_modules/moment/src/moment.js` URL.

Example

An import map can remap a class of module specifiers into a class of URLs by using trailing slashes, like so:

```
{
  "imports": {
    "moment/": "/node_modules/moment/src/"
  }
}
```

This enables statements like `import localeData from "moment/locale/zh-cn.js";` to work, fetching and evaluating the JavaScript module at the `/node_modules/moment/src/moment/locale/zh-cn.js` URL. Such trailing-slash mappings are often combined with bare-specifier mappings, e.g.

```
{
```

```
  "imports": {
    "moment": "/node_modules/moment/src/moment.js",
    "moment/": "/node_modules/moment/src/"
  }
}
```

so that both the "main module" specified by "`moment`" and the "submodules" specified by paths such as "`moment/locale/zh-cn.js`" are available.

Example

Bare specifiers are not the only type of module specifiers which import maps can remap. "URL-like" specifiers, i.e., those that are either parseable as absolute URLs or start with "`/`", "`./`", or "`../`", can be remapped as well:

```
{
  "imports": {
    "https://cdn.example.com/vue/dist/vue.runtime.esm.js": "/node_modules/vue/dist/
vue.runtime.esm.js",
    "/js/app.mjs": "/js/app-8e0d62a03.mjs",
    "../helpers/": "https://cdn.example/helpers/"
  }
}
```

Note how the URL to be remapped, as well as the URL being mapped to, can be specified either as absolute URLs, or as relative URLs starting with "`/`", "`./`", or "`../`". (They cannot be specified as relative URLs without those starting sigils, as those help distinguish from bare module specifiers.) Also note how the trailing slash mapping[p1058] works in this context as well.

Such remappings operate on the post-canonicalization URL, and do not require a match between the literal strings supplied in the import map key and the imported module specifier. So for example, if this import map was included on `https://example.com/app.html`, then not only would `import "/js/app.mjs"` be remapped, but so would `import "./js/app.mjs"` and `import "./foo/../js/app.mjs"`.

Example

All previous examples have globally remapped module specifiers, by using the top-level "`imports`" key in the import map. The top-level "`scopes`" key can be used to provide localized remappings, which only apply when the referring module matches a specific URL prefix. For example:

```
{
  "scopes": {
    "/a/" : {
      "moment": "/node_modules/moment/src/moment.js"
    },
    "/b/" : {
      "moment": "https://cdn.example.com/moment/src/moment.js"
    }
  }
}
```

With this import map, the statement `import "moment"` will have different meanings depending on which referrer script contains the statement:

- Inside scripts located under `/a/`, this will import `/node_modules/moment/src/moment.js`.
- Inside scripts located under `/b/`, this will import `https://cdn.example.com/moment/src/moment.js`.
- Inside scripts located under `/c/`, this will fail to resolve and thus throw an exception.

A typical usage of scopes is to allow multiple versions of the "same" module to exist in a web application, with some parts of the module graph importing one version, and other parts importing another version.

Example

Scopes can overlap each other, and overlap the global "`imports`" specifier map. At resolution time, scopes are consulted in order of most- to least-specific, where specificity is measured by sorting the scopes using the code unit less than operation. So, for example, "`/scope2/scope3/`" is treated as more specific than "`/scope2/`", which is treated as more specific than the top-level (unscoped) mappings.

The following import map illustrates this:

```
{
  "imports": {
    "a": "/a-1.mjs",
    "b": "/b-1.mjs",
    "c": "/c-1.mjs"
  },
  "scopes": {
    "/scope2/": {
      "a": "/a-2.mjs"
    },
    "/scope2/scope3/": {
      "b": "/b-3.mjs"
    }
  }
}
```

This results in the following resolutions (using relative URLs for brevity):

		Specifier		
		"a"	"b"	"c"
Referrer	/scope1/r.mjs	/a-1.mjs	/b-1.mjs	/c-1.mjs
	/scope2/r.mjs	/a-2.mjs	/b-1.mjs	/c-1.mjs
	/scope2/scope3/r.mjs	/a-2.mjs	/b-3.mjs	/c-1.mjs

The child text content of a `script` [p638] element representing an import map [p1060] must match the following **import map authoring requirements**:

- It must be valid JSON. [JSON] [p1414]
- The JSON must represent a JSON object, with at most the two keys "`imports`" and "`scopes`".
- The values corresponding to the "`imports`" and "`scopes`" keys, if present, must themselves be JSON objects.
- The value corresponding to the "`imports`" key, if present, must be a valid module specifier map [p1060].
- The value corresponding to the "`scopes`" key, if present, must be a JSON object, whose keys are valid URL strings and whose values are valid module specifier maps [p1060].

A **valid module specifier map** is a JSON object that meets the following requirements:

- All of its keys must be nonempty.
- All of its values must be strings.
- Each value must be either a valid absolute URL or a valid URL string that starts with "`/`", "`./`", or "`../`".
- If a given key ends with "`/`", then the corresponding value must also.

8.1.5.3 Import map processing model §[p1060]

Formally, an **import map** is a struct with two items:

- **imports**, a module specifier map [p1061]; and

- **scopes**, an ordered map of URLs to module specifier maps[p1061].

A **module specifier map** is an ordered map whose keys are strings and whose values are either URLs or nulls.

An **empty import map** is an import map[p1060] with its imports[p1060] and scopes[p1061] both being empty maps.

Each `Window`[p892] has an **import map**, initially an empty import map[p1061].

Each `Window`[p892] has an **import maps allowed** boolean, initially true.

To **disallow further import maps** given an environment settings object[p1032] *settingsObject*:

1. Let *global* be *settingsObject*'s global object[p1033].
2. If *global* does not implement `Window`[p892], then return.
3. Set *global*'s import maps allowed[p1061] to false.

Note

Import maps are currently disallowed once any module loading has started, or once a single import map is loaded. These restrictions might be lifted in future specification revisions.

To **parse an import map string**, given a string *input* and a URL *baseURL*:

1. Let *parsed* be the result of parsing a JSON string to an Infra value given *input*.
2. If *parsed* is not an ordered map, then throw a `TypeError` indicating that the top-level value needs to be a JSON object.
3. Let *sortedAndNormalizedImports* be an empty ordered map.
4. If *parsed*["`imports`"] exists, then:
    1. If *parsed*["`imports`"] is not an ordered map, then throw a `TypeError` indicating that the value for the "`imports`" top-level key needs to be a JSON object.
    2. Set *sortedAndNormalizedImports* to the result of sorting and normalizing a module specifier map[p1062] given *parsed*["`imports`"] and *baseURL*.
5. Let *sortedAndNormalizedScopes* be an empty ordered map.
6. If *parsed*["`scopes`"] exists, then:
    1. If *parsed*["`scopes`"] is not an ordered map, then throw a `TypeError` indicating that the value for the "`scopes`" top-level key needs to be a JSON object.
    2. Set *sortedAndNormalizedScopes* to the result of sorting and normalizing scopes[p1062] given *parsed*["`scopes`"] and *baseURL*.
7. If *parsed*'s keys contains any items besides "`imports`" or "`scopes`", then the user agent should report a warning to the console indicating that an invalid top-level key was present in the import map.

    Note

    This can help detect typos. It is not an error, because that would prevent any future extensions from being added backward-compatibly.
8. Return an import map[p1060] whose imports[p1060] are *sortedAndNormalizedImports* and whose scopes[p1061] are *sortedAndNormalizedScopes*.

Example

The import map[p1060] that results from this parsing algorithm is highly normalized. For example, given a base URL of `https://example.com/base/page.html`, the input

```
{
  "imports": {
    "/app/helper": "node_modules/helper/index.mjs",
    "lodash": "/node_modules/lodash-es/lodash.js"
  }
}
```

will generate an import map[p1060] with imports[p1060] of

```
«[
  "https://example.com/app/helper" → https://example.com/base/node_modules/helper/index.mjs
  "lodash" → https://example.com/node_modules/lodash-es/lodash.js
]»
```

and (despite nothing being present in the input string) an empty ordered map for its scopes[p1061].

To **sort and normalize a module specifier map**, given an ordered map *originalMap* and a URL *baseURL*:

1. Let *normalized* be an empty ordered map.
2. For each *specifierKey* → *value* of *originalMap*:
    1. Let *normalizedSpecifierKey* be the result of normalizing a specifier key[p1063] given *specifierKey* and *baseURL*.
    2. If *normalizedSpecifierKey* is null, then continue.
    3. If *value* is not a string, then:
        1. The user agent may report a warning to the console indicating that addresses need to be strings.
        2. Set *normalized*[*normalizedSpecifierKey*] to null.
        3. Continue.
    4. Let *addressURL* be the result of resolving a URL-like module specifier[p1057] given *value* and *baseURL*.
    5. If *addressURL* is null, then:
        1. The user agent may report a warning to the console indicating that the address was invalid.
        2. Set *normalized*[*normalizedSpecifierKey*] to null.
        3. Continue.
    6. If *specifierKey* ends with U+002F (/), and the serialization of *addressURL* does not end with U+002F (/), then:
        1. The user agent may report a warning to the console indicating that an invalid address was given for the specifier key *specifierKey*; since *specifierKey* ends with a slash, the address needs to as well.
        2. Set *normalized*[*normalizedSpecifierKey*] to null.
        3. Continue.
    7. Set *normalized*[*normalizedSpecifierKey*] to *addressURL*.
3. Return the result of sorting in descending order *normalized*, with an entry *a* being less than an entry *b* if *a*'s key is code unit less than *b*'s key.

To **sort and normalize scopes**, given an ordered map *originalMap* and a URL *baseURL*:

1. Let *normalized* be an empty ordered map.
2. For each *scopePrefix* → *potentialSpecifierMap* of *originalMap*:
    1. If *potentialSpecifierMap* is not an ordered map, then throw a `TypeError` indicating that the value of the scope with prefix *scopePrefix* needs to be a JSON object.

2. Let *scopePrefixURL* be the result of URL parsing *scopePrefix* with *baseURL*.
3. If *scopePrefixURL* is failure, then:
    1. The user agent may report a warning to the console that the scope prefix URL was not parseable.
    2. Continue.
4. Let *normalizedScopePrefix* be the serialization of *scopePrefixURL*.
5. Set *normalized*[*normalizedScopePrefix*] to the result of sorting and normalizing a module specifier map[p1062] given *potentialSpecifierMap* and *baseURL*.

3. Return the result of sorting in descending order *normalized*, with an entry *a* being less than an entry *b* if *a*'s key is code unit less than *b*'s key.

Note

In the above two algorithms, sorting keys and scopes in descending order has the effect of putting `"foo/bar/"` *before* `"foo/"`*. This in turn gives* `"foo/bar/"` *a higher priority than* `"foo/"` *during module specifier resolution*[p1056]*.*

To **normalize a specifier key**, given a string *specifierKey* and a URL *baseURL*:

1. If *specifierKey* is the empty string, then:
    1. The user agent may report a warning to the console indicating that specifier keys may not be the empty string.
    2. Return null.
2. Let *url* be the result of resolving a URL-like module specifier[p1057], given *specifierKey* and *baseURL*.
3. If *url* is not null, then return the serialization of *url*.
4. Return *specifierKey*.

8.1.6 JavaScript specification host hooks §[p1063]

The JavaScript specification contains a number of implementation-defined abstract operations, that vary depending on the host environment. This section defines them for user agent hosts.

8.1.6.1 HostEnsureCanAddPrivateElement(*O*) §[p1063]

JavaScript contains an implementation-defined HostEnsureCanAddPrivateElement(*O*) abstract operation. User agents must use the following implementation: [JAVASCRIPT][p1414]

1. If *O* is a `WindowProxy`[p904] object, or implements `Location`[p908], then return Completion { [[Type]]: throw, [[Value]]: a new `TypeError` }.
2. Return NormalCompletion(unused).

Note

JavaScript private fields can be applied to arbitrary objects. Since this can dramatically complicate implementation for particularly-exotic host objects, the JavaScript language specification provides this hook to allow hosts to reject private fields on objects meeting a host-defined criteria. In the case of HTML, `WindowProxy`[p904] *and* `Location`[p908] *have complicated semantics — particularly around navigation and security — that make implementation of private field semantics challenging, so our implementation simply rejects those objects.*

8.1.6.2 HostEnsureCanCompileStrings(*realm*) §[p1063]

JavaScript contains an implementation-defined HostEnsureCanCompileStrings(*realm*) abstract operation. User agents must use the

following implementation: [JAVASCRIPT][p1414]

1. Perform ? EnsureCSPDoesNotBlockStringCompilation(*realm*). [CSP][p1411]

8.1.6.3 HostPromiseRejectionTracker(*promise*, *operation*) §[p10 64]

JavaScript contains an implementation-defined HostPromiseRejectionTracker(*promise*, *operation*) abstract operation. User agents must use the following implementation: [JAVASCRIPT][p1414]

1. Let *script* be the running script[p1052].
2. If *script* is a classic script[p1040] and *script*'s muted errors[p1040] is true, then return.
3. Let *settings object* be the current settings object[p1038].
4. If *script* is not null, then set *settings object* to *script*'s settings object[p1040].
5. If *operation* is "`reject`", then:
    1. Append *promise* to *settings object*'s about-to-be-notified rejected promises list[p1032].
6. If *operation* is "`handle`", then:
    1. If *settings object*'s about-to-be-notified rejected promises list[p1032] contains *promise*, then remove *promise* from that list and return.
    2. If *settings object*'s outstanding rejected promises weak set[p1032] does not contain *promise*, then return.
    3. Remove *promise* from *settings object*'s outstanding rejected promises weak set[p1032].
    4. Let *global* be *settings object*'s global object[p1033].
    5. Queue a global task[p1073] on the DOM manipulation task source[p1080] given *global* to fire an event named `rejectionhandled`[p1407] at *global*, using `PromiseRejectionEvent`[p1055], with the `promise`[p1055] attribute initialized to *promise*, and the `reason`[p1055] attribute initialized to *promise*.[[PromiseResult]].

8.1.6.4 Job-related host hooks §[p10 64]

The JavaScript specification defines Jobs to be scheduled and run later by the host, as well as JobCallback Records which encapsulate JavaScript functions that are called as part of jobs. The JavaScript specification contains a number of implementation-defined abstract operations that lets the host define how jobs are scheduled and how JobCallbacks are handled. HTML uses these abstract operations to track the incumbent settings object[p1036] in promises and `FinalizationRegistry` callbacks by saving and restoring the incumbent settings object[p1036] and a JavaScript execution context for the active script[p1041] in JobCallbacks. This section defines them for user agent hosts.

8.1.6.4.1 HostCallJobCallback(callback, V, argumentsList) §[p10 64]

JavaScript contains an implementation-defined HostCallJobCallback(*callback*, *V*, *argumentsList*) abstract operation to let hosts restore state when invoking JavaScript callbacks from inside tasks. User agents must use the following implementation: [JAVASCRIPT][p1414]

1. Let *incumbent settings* be *callback*.[[HostDefined]].[[IncumbentSettings]].
2. Let *script execution context* be *callback*.[[HostDefined]].[[ActiveScriptContext]].
3. Prepare to run a callback[p1036] with *incumbent settings*.

    Note

    This affects the incumbent[p1033] concept while the callback runs.

4. If *script execution context* is not null, then push *script execution context* onto the JavaScript execution context stack.

Note

This affects the active script[p1041] while the callback runs.

5. Let *result* be Call(*callback*.[[Callback]], *V*, *argumentsList*).
6. If *script execution context* is not null, then pop *script execution context* from the JavaScript execution context stack.
7. Clean up after running a callback[p1036] with *incumbent settings*.
8. Return *result*.

8.1.6.4.2 HostEnqueueFinalizationRegistryCleanupJob(finalizationRegistry) §[p1065]

JavaScript has the ability to register objects with `FinalizationRegistry` objects, in order to schedule a cleanup action if they are found to be garbage collected. The JavaScript specification contains an implementation-defined HostEnqueueFinalizationRegistryCleanupJob(*finalizationRegistry*) abstract operation to schedule the cleanup action.

Note

The timing and occurrence of cleanup work is implementation-defined in the JavaScript specification. User agents might differ in when and whether an object is garbage collected, affecting both whether the return value of the `WeakRef.prototype.deref()` method is undefined, and whether `FinalizationRegistry` cleanup callbacks occur. There are well-known cases in popular web browsers where objects are not accessible to JavaScript, but they remain retained by the garbage collector indefinitely. HTML clears kept-alive `WeakRef` objects in the perform a microtask checkpoint[p1077] algorithm. Authors would be best off not depending on the timing details of garbage collection implementations.

Cleanup actions do not take place interspersed with synchronous JavaScript execution, but rather happen in queued tasks[p1071]. User agents must use the following implementation: [JAVASCRIPT][p1414]

1. Let *global* be *finalizationRegistry*.[[Realm]]'s global object[p1033].
2. Queue a global task[p1073] on the **JavaScript engine task source** given *global* to perform the following steps:
    1. Let *entry* be *finalizationRegistry*.[[CleanupCallback]].[[Callback]].[[Realm]]'s environment settings object[p1033].
    2. Check if we can run script[p1052] with *entry*. If this returns "do not run", then return.
    3. Prepare to run script[p1052] with *entry*.

    Note

    This affects the entry[p1033] concept while the cleanup callback runs.

    4. Let *result* be the result of performing CleanupFinalizationRegistry(*finalizationRegistry*).
    5. Clean up after running script[p1052] with *entry*.
    6. If *result* is an abrupt completion, then report the exception[p1053] given by *result*.[[Value]].

8.1.6.4.3 HostEnqueueGenericJob(job, realm) §[p1065]

JavaScript contains an implementation-defined HostEnqueueGenericJob(*job*, *realm*) abstract operation to perform generic jobs in a particular realm (e.g., resolve promises resulting from `Atomics.waitAsync`). User agents must use the following implementation: [JAVASCRIPT][p1414]

1. Let *global* be *realm*'s global object[p1033].
2. Queue a global task[p1073] on the JavaScript engine task source[p1065] given *global* to perform *job*().

8.1.6.4.4 HostEnqueuePromiseJob(job, realm) §[p1065]

JavaScript contains an implementation-defined HostEnqueuePromiseJob(*job*, *realm*) abstract operation to schedule Promise-related

operations. HTML schedules these operations in the microtask queue. User agents must use the following implementation: [JAVASCRIPT][p1414]

1. If *realm* is not null, then let *job settings* be the settings object[p1033] for *realm*. Otherwise, let *job settings* be null.

   Note

   If realm *is not null, it is the realm of the author code that will run. When* job *is returned by NewPromiseReactionJob, it is the realm of the promise's handler function. When* job *is returned by NewPromiseResolveThenableJob, it is the realm of the* `then` *function.*

   If realm *is null, either no author code will run or author code is guaranteed to throw. For the former, the author may not have passed in code to run, such as in* `promise.then(null, null)`*. For the latter, it is because a revoked Proxy was passed. In both cases, all the steps below that would otherwise use* job settings *get skipped.*

2. Queue a microtask[p1073] on the surrounding agent's event loop[p1071] to perform the following steps:

   1. If *job settings* is not null, then check if we can run script[p1052] with *job settings*. If this returns "do not run" then return.

   2. If *job settings* is not null, then prepare to run script[p1052] with *job settings*.

      Note

      This affects the entry[p1033] concept while the job runs.

   3. Let *result* be *job*().

      Note

      job *is an abstract closure returned by NewPromiseReactionJob or NewPromiseResolveThenableJob. The promise's handler function when* job *is returned by NewPromiseReactionJob, and the* `then` *function when* job *is returned by NewPromiseResolveThenableJob, are wrapped in JobCallback Records. HTML saves the incumbent settings object[p1036] and a JavaScript execution context for to the active script[p1041] in HostMakeJobCallback[p1066] and restores them in HostCallJobCallback[p1064].*

   4. If *job settings* is not null, then clean up after running script[p1052] with *job settings*.

   5. If *result* is an abrupt completion, then report the exception[p1053] given by *result*.[[Value]].

8.1.6.4.5 HostEnqueueTimeoutJob(job, realm, milliseconds) §[p1066]

JavaScript contains an implementation-defined HostEnqueueTimeoutJob(*job*, *milliseconds*) abstract operation to schedule an operation to be performed after a timeout. HTML schedules these operations using run steps after a timeout[p1104]. User agents must use the following implementation: [JAVASCRIPT][p1414]

1. Let *global* be *realm*'s global object[p1033].

2. Let *timeoutStep* be an algorithm step which queues a global task[p1073] on the JavaScript engine task source[p1065] given *global* to perform *job*().

3. Run steps after a timeout[p1104] given *global*, "`JavaScript`", *milliseconds*, and *timeoutStep*.

8.1.6.4.6 HostMakeJobCallback(callable) §[p1066]

JavaScript contains an implementation-defined HostMakeJobCallback(*callable*) abstract operation to let hosts attach state to JavaScript callbacks that are called from inside task[p1071]s. User agents must use the following implementation: [JAVASCRIPT][p1414]

1. Let *incumbent settings* be the incumbent settings object[p1036].

2. Let *active script* be the active script[p1041].

3. Let *script execution context* be null.

4. If *active script* is not null, set *script execution context* to a new JavaScript execution context, with its Function field set to null,

its Realm field set to *active script*'s settings object[p1040]'s realm[p1033], and its ScriptOrModule set to *active script*'s record[p1040].

Note

As seen below, this is used in order to propagate the current active script[p1041] forward to the time when the job callback is invoked.

Example

A case where *active script* is non-null, and saving it in this way is useful, is the following:

```
Promise.resolve('import(`./example.mjs`)').then(eval);
```

Without this step (and the steps that use it in HostCallJobCallback[p1064]), there would be no active script[p1041] when the `import()` expression is evaluated, since `eval()` is a built-in function that does not originate from any particular script[p1040].

With this step in place, the active script is propagated from the above code into the job, allowing `import()` to use the original script's base URL[p1040] appropriately.

Example

active script can be null if the user clicks on the following button:

```
<button onclick="Promise.resolve('import(`./example.mjs`)').then(eval)">Click me</button>
```

In this case, the JavaScript function for the event handler[p1083] will be created by the get the current value of the event handler[p1088] algorithm, which creates a function with null [[ScriptOrModule]] value. Thus, when the promise machinery calls HostMakeJobCallback[p1066], there will be no active script[p1041] to pass along.

As a consequence, this means that when the `import()` expression is evaluated, there will still be no active script[p1041]. Fortunately that is handled by our implementation of HostLoadImportedModule[p1069] by falling back to using the current settings object[p1038]'s API base URL[p1032].

5. Return the JobCallback Record { [[Callback]]: *callable*, [[HostDefined]]: { [[IncumbentSettings]]: *incumbent settings*, [[ActiveScriptContext]]: *script execution context* } }.

8.1.6.5 Module-related host hooks §[p1067]

The JavaScript specification defines a syntax for modules, as well as some host-agnostic parts of their processing model. This specification defines the rest of their processing model: how the module system is bootstrapped, via the `script`[p638] element with `type`[p639] attribute set to "`module`", and how modules are fetched, resolved, and executed. [JAVASCRIPT][p1414]

Note

Although the JavaScript specification speaks in terms of "scripts" versus "modules", in general this specification speaks in terms of classic scripts[p1040] versus module scripts[p1040], since both of them use the `script`[p638] element.

For web developers (non-normative)

***modulePromise* = `import(`*specifier*`)`**

Returns a promise for the module namespace object for the module script[p1040] identified by *specifier*. This allows dynamic importing of module scripts at runtime, instead of statically using the `import` statement form. The specifier will be resolved[p1056] relative to the active script[p1041].

The returned promise will be rejected if an invalid specifier is given, or if a failure is encountered while fetching[p1069] or evaluating the resulting module graph.

This syntax can be used inside both classic[p1040] and module scripts[p1040]. It thus provides a bridge into the module-script world, from the classic-script world.

***url* = `import.meta.url`[p1069]**

Returns the active module script[p1041]'s base URL[p1040].

This syntax can only be used inside module scripts[p1040].

***url* = import.meta.resolve[p1069](*specifier*)**

Returns *specifier*, resolved[p1056] relative to the active script[p1041]. That is, this returns the URL that would be imported by using `import(specifier)`.

Throws a `TypeError` exception if an invalid specifier is given.

This syntax can only be used inside module scripts[p1040].

A **module map** is a map keyed by tuples consisting of a URL record and a string. The URL record is the request URL at which the module was fetched, and the string indicates the type of the module (e.g. "`javascript`"). The module map[p1068]'s values are either a module script[p1040], null (used to represent failed fetches), or a placeholder value "`fetching`". Module maps[p1068] are used to ensure that imported module scripts are only fetched, parsed, and evaluated once per `Document`[p127] or worker[p1150].

Example

Since module maps[p1068] are keyed by (URL, module type), the following code will create three separate entries in the module map[p1068], since it results in three different (URL, module type) tuples (all with "`javascript`" type):

```
import "https://example.com/module.mjs";
import "https://example.com/module.mjs#map-buster";
import "https://example.com/module.mjs?debug=true";
```

That is, URL queries and fragments can be varied to create distinct entries in the module map[p1068]; they are not ignored. Thus, three separate fetches and three separate module evaluations will be performed.

In contrast, the following code would only create a single entry in the module map[p1068], since after applying the URL parser to these inputs, the resulting URL records are equal:

```
import "https://example.com/module2.mjs";
import "https:example.com/module2.mjs";
import "https://///example.com\\module2.mjs";
import "https://example.com/foo/../module2.mjs";
```

So in this second example, only one fetch and one module evaluation will occur.

Note that this behavior is the same as how shared workers[p1176] are keyed by their parsed constructor url[p1169].

Example

Since module type is also part of the module map[p1068] key, the following code will create two separate entries in the module map[p1068] (the type is "`javascript`" for the first, and "`css`" for the second):

```
<script type=module>
  import "https://example.com/module";
</script>
<script type=module>
  import "https://example.com/module" with { type: "css" };
</script>
```

This can result in two separate fetches and two separate module evaluations being performed.

In practice, due to the as-yet-unspecified memory cache (see issue #6110) the resource may only be fetched once in WebKit and Blink-based browsers. Additionally, as long as all module types are mutually exclusive, the module type check in fetch a single module script[p1047] will fail for at least one of the imports, so at most one module evaluation will occur.

The purpose of including the type in the module map[p1068] key is so that an import with the wrong type attribute does not prevent a different import of the same specifier but with the correct type from succeeding.

Example

JavaScript module scripts are the default import type when importing from another JavaScript module; that is, when an `import` statement lacks a `type` import attribute the imported module script's type will be JavaScript. Attempting to import a JavaScript resource using an `import` statement with a `type` import attribute will fail:

```
<script type="module">
    // All of the following will fail, assuming that the imported .mjs files are served with a
    // JavaScript MIME type. JavaScript module scripts are the default and cannot be imported with
    // any import type attribute.
    import foo from "./foo.mjs" with { type: "javascript" };
    import foo2 from "./foo2.mjs" with { type: "js" };
    import foo3 from "./foo3.mjs" with { type: "" };
    await import("./foo4.mjs", { with: { type: null } });
    await import("./foo5.mjs", { with: { type: undefined } });
</script>
```

✔ MDN

8.1.6.5.1 HostGetImportMetaProperties(moduleRecord) §p10 69

JavaScript contains an implementation-defined HostGetImportMetaProperties abstract operation. User agents must use the following implementation: [JAVASCRIPT]p1414

1. Let *moduleScript* be *moduleRecord*.[[HostDefined]].
2. Assert: *moduleScript*'s base URLp1040 is not null, as *moduleScript* is a JavaScript module scriptp1040.
3. Let *urlString* be *moduleScript*'s base URLp1040, serialized.
4. Let *steps* be the following steps, given the argument *specifier*:
    1. Set *specifier* to ? ToString(*specifier*).
    2. Let *url* be the result of resolving a module specifierp1056 given *moduleScript* and *specifier*.
    3. Return the serialization of *url*.
5. Let *resolveFunction* be ! CreateBuiltinFunction(*steps*, 1, "`resolve`", « »).
6. Return « Record { [[Key]]: "**`url`**", [[Value]]: *urlString* }, Record { [[Key]]: "**`resolve`**", [[Value]]: *resolveFunction* } ».

8.1.6.5.2 HostGetSupportedImportAttributes() §p10 69

The *Import Attributes* proposal contains an implementation-defined HostGetSupportedImportAttributes abstract operation. User agents must use the following implementation: [JSIMPORTATTRIBUTES]p1414

1. Return « "`type`" ».

8.1.6.5.3 HostLoadImportedModule(referrer, moduleRequest, loadState, payload) §p10 69

JavaScript contains an implementation-defined HostLoadImportedModule abstract operation. User agents must use the following implementation: [JAVASCRIPT]p1414

1. Let *settingsObject* be the current settings objectp1038.
2. If *settingsObject*'s global objectp1033 implements `WorkletGlobalScope`p1184 or `ServiceWorkerGlobalScope` and *loadState* is undefined, then:

Note

loadState *is undefined when the current fetching process has been initiated by a dynamic* `import()` *call, either directly or when loading the transitive dependencies of the dynamically imported module.*

1. Let *completion* be Completion Record { [[Type]]: throw, [[Value]]: a new `TypeError`, [[Target]]: empty }.
2. Perform FinishLoadingImportedModule(*referrer*, *moduleRequest*, *payload*, *completion*).
3. Return.

3. Let *referencingScript* be null.
4. Let *fetchOptions* be the default classic script fetch options[p1041].
5. Let *fetchReferrer* be "`client`".
6. If *referrer* is a Script Record or a Module Record, then:
   1. Set *referencingScript* to *referrer*.[[HostDefined]].
   2. Set *settingsObject* to *referencingScript*'s settings object[p1040].
   3. Set *fetchOptions* to the new descendant script fetch options[p1042] for *referencingScript*'s fetch options[p1040].
   4. Assert: *fetchOptions* is not null, as *referencingScript* is a classic script[p1040] or a JavaScript module script[p1040].
   5. Set *fetchReferrer* to *referrer*'s base URL[p1040].

Example

referrer is usually a Script Record or a Module Record, but it will not be so for event handlers per the get the current value of the event handler[p1088] algorithm. For example, given:

```
<button onclick="import('./foo.mjs')">Click me</button>
```

If a `click` event occurs, then at the time the `import()` expression runs, GetActiveScriptOrModule will return null, and this operation will receive the current realm as a fallback *referrer*.

7. Disallow further import maps[p1061] given *settingsObject*.
8. Let *url* be the result of resolving a module specifier[p1056] given *referencingScript* and *moduleRequest*.[[Specifier]], catching any exceptions. If they throw an exception, let *resolutionError* be the thrown exception.
9. If the previous step threw an exception, then:
   1. Let *completion* be Completion Record { [[Type]]: throw, [[Value]]: *resolutionError*, [[Target]]: empty }.
   2. Perform FinishLoadingImportedModule(*referrer*, *moduleRequest*, *payload*, *completion*).
   3. Return.
10. Let *destination* be "`script`".
11. If *loadState* is not undefined, then set *destination* to *loadState*.[[Destination]].
12. Fetch a single imported module script[p1048] given *url*, *settings object*, *destination*, *fetchOptions*, *fetchReferrer*, *moduleRequest*, and *onSingleFetchComplete* as defined below. If *loadState* is not undefined and *loadState*.[[PerformFetch]] is not null, pass *loadState*.[[PerformFetch]] along as well.

    onSingleFetchComplete given *moduleScript* is the following algorithm:

    1. Let *completion* be null.
    2. If *moduleScript* is null, then set *completion* to Completion Record { [[Type]]: throw, [[Value]]: a new `TypeError`, [[Target]]: empty }.
    3. Otherwise, if *moduleScript*'s parse error[p1040] is not null, then:
       1. Let *parseError* be *moduleScript*'s parse error[p1040].
       2. Set *completion* to Completion Record { [[Type]]: throw, [[Value]]: *parseError*, [[Target]]: empty }.
       3. If *loadState* is not undefined and *loadState*.[[ParseError]] is null, set *loadState*.[[ParseError]] to *parseError*.

4. Otherwise, set *completion* to Completion Record { [[Type]]: normal, [[Value]]: *result*'s record[p1040], [[Target]]: empty }.

5. Perform FinishLoadingImportedModule(*referrer*, *moduleRequest*, *payload*, *completion*).

8.1.7 Event loops §[p1071]

8.1.7.1 Definitions §[p1071]

To coordinate events, user interaction, scripts, rendering, networking, and so forth, user agents must use **event loops** as described in this section. Each agent has an associated **event loop**, which is unique to that agent.

The event loop[p1071] of a similar-origin window agent[p1028] is known as a **window event loop**. The event loop[p1071] of a dedicated worker agent[p1028], shared worker agent[p1028], or service worker agent[p1028] is known as a **worker event loop**. And the event loop[p1071] of a worklet agent[p1028] is known as a **worklet event loop**.

Note

Event loops[p1071] do not necessarily correspond to implementation threads. For example, multiple window event loops[p1071] could be cooperatively scheduled in a single thread.

However, for the various worker agents that are allocated with [[CanBlock]] set to true, the JavaScript specification does place requirements on them regarding forward progress, which effectively amount to requiring dedicated per-agent threads in those cases.

An event loop[p1071] has one or more **task queues**. A task queue[p1071] is a set of tasks[p1071].

Note

Task queues[p1071] are sets, not queues, because the event loop processing model[p1074] grabs the first runnable[p1072] *task[p1071] from the chosen queue, instead of dequeuing the first task.*

Note

The microtask queue[p1072] is not a task queue[p1071].

Tasks encapsulate algorithms that are responsible for such work as:

Events

Dispatching an `Event` object at a particular `EventTarget` object is often done by a dedicated task.

Note

Not all events are dispatched using the task queue[p1071]; many are dispatched during other tasks.

Parsing

The HTML parser[p1210] tokenizing one or more bytes, and then processing any resulting tokens, is typically a task.

Callbacks

Calling a callback is often done by a dedicated task.

Using a resource

When an algorithm fetches a resource, if the fetching occurs in a non-blocking fashion then the processing of the resource once some or all of the resource is available is performed by a task.

Reacting to DOM manipulation

Some elements have tasks that trigger in response to DOM manipulation, e.g. when that element is inserted into the document[p46].

Formally, a **task** is a struct which has:

Steps

A series of steps specifying the work to be done by the task.

A *source*

One of the task sources[p1072], used to group and serialize related tasks.

A *document*

A `Document`[p127] associated with the task, or null for tasks that are not in a window event loop[p1071].

A *script evaluation environment settings object set*

A set of environment settings objects[p1032] used for tracking script evaluation during the task.

A task[p1071] is **runnable** if its document[p1072] is either null or fully active[p966].

Per its source[p1072] field, each task[p1071] is defined as coming from a specific **task source**. For each event loop[p1071], every task source[p1072] must be associated with a specific task queue[p1071].

Note

Essentially, task sources[p1072] are used within standards to separate logically-different types of tasks, which a user agent might wish to distinguish between. Task queues[p1071] are used by user agents to coalesce task sources within a given event loop[p1071].

Example

For example, a user agent could have one task queue[p1071] for mouse and key events (to which the user interaction task source[p1080] is associated), and another to which all other task sources[p1072] are associated. Then, using the freedom granted in the initial step of the event loop processing model[p1074], it could give keyboard and mouse events preference over other tasks three-quarters of the time, keeping the interface responsive but not starving other task queues. Note that in this setup, the processing model still enforces that the user agent would never process events from any one task source[p1072] out of order.

Each event loop[p1071] has a **currently running task**, which is either a task[p1071] or null. Initially, this is null. It is used to handle reentrancy.

Each event loop[p1071] has a **microtask queue**, which is a queue of microtasks[p1072], initially empty. A **microtask** is a colloquial way of referring to a task[p1071] that was created via the queue a microtask[p1073] algorithm.

Each event loop[p1071] has a **performing a microtask checkpoint** boolean, which is initially false. It is used to prevent reentrant invocation of the perform a microtask checkpoint[p1077] algorithm.

Each window event loop[p1071] has a `DOMHighResTimeStamp` **last render opportunity time**, initially set to zero.

Each window event loop[p1071] has a `DOMHighResTimeStamp` **last idle period start time**, initially set to zero.

To get the **same-loop windows** for a window event loop[p1071] *loop*, return all `Window`[p892] objects whose relevant agent[p1029]'s event loop[p1071] is *loop*.

8.1.7.2 Queuing tasks §[p1072]

To **queue a task** on a task source[p1072] *source*, which performs a series of steps *steps*, optionally given an event loop *event loop* and a document *document*:

1. If *event loop* was not given, set *event loop* to the implied event loop[p1073].
2. If *document* was not given, set *document* to the implied document[p1073].
3. Let *task* be a new task[p1071].
4. Set *task*'s steps[p1072] to *steps*.
5. Set *task*'s source[p1072] to *source*.
6. Set *task*'s document[p1072] to the *document*.
7. Set *task*'s script evaluation environment settings object set[p1072] to an empty set.

8. Let *queue* be the task queue[p1071] to which *source* is associated on *event loop*.

9. Append *task* to *queue*.

⚠Warning!

Failing to pass an event loop and document to queue a task[p1072] means relying on the ambiguous and poorly-specified implied event loop[p1073] and implied document[p1073] concepts. Specification authors should either always pass these values, or use the wrapper algorithms queue a global task[p1073] or queue an element task[p1073] instead. Using the wrapper algorithms is recommended.

To **queue a global task** on a task source[p1072] *source*, with a global object[p1033] *global* and a series of steps *steps*:

1. Let *event loop* be *global*'s relevant agent[p1029]'s event loop[p1071].

2. Let *document* be *global*'s associated `Document`[p894], if *global* is a `Window`[p892] object; otherwise null.

3. Queue a task[p1072] given *source*, *event loop*, *document*, and *steps*.

To **queue an element task** on a task source[p1072] *source*, with an element *element* and a series of steps *steps*:

1. Let *global* be *element*'s relevant global object[p1039].

2. Queue a global task[p1073] given *source*, *global*, and *steps*.

To **queue a microtask** which performs a series of steps *steps*, optionally given an event loop *event loop* and a document *document*:

1. If *event loop* was not given, set *event loop* to the implied event loop[p1073].

2. If *document* was not given, set *document* to the implied document[p1073].

3. Let *microtask* be a new task[p1071].

4. Set *microtask*'s steps[p1072] to *steps*.

5. Set *microtask*'s source[p1072] to the **microtask task source**.

6. Set *microtask*'s document[p1072] to *document*.

7. Set *microtask*'s script evaluation environment settings object set[p1072] to an empty set.

8. Enqueue *microtask* on *event loop*'s microtask queue[p1072].

Note

It is possible for a microtask[p1072] to be moved to a regular task queue[p1071], if, during its initial execution, it spins the event loop[p1078]. This is the only case in which the source[p1072], document[p1072], and script evaluation environment settings object set[p1072] of the microtask are consulted; they are ignored by the perform a microtask checkpoint[p1077] algorithm.

The **implied event loop** when queuing a task is the one that can deduced from the context of the calling algorithm. This is generally unambiguous, as most specification algorithms only ever involve a single agent (and thus a single event loop[p1071]). The exception is algorithms involving or specifying cross-agent communication (e.g., between a window and a worker); for those cases, the implied event loop[p1073] concept must not be relied upon and specifications must explicitly provide an event loop[p1071] when queuing a task[p1072] or microtask[p1073].

The **implied document** when queuing a task on an event loop[p1071] *event loop* is determined as follows:

1. If *event loop* is not a window event loop[p1071], then return null.

2. If the task is being queued in the context of an element, then return the element's node document.

3. If the task is being queued in the context of a browsing context[p961], then return the browsing context's active document[p961].

4. If the task is being queued by or for a script[p1040], then return the script's settings object[p1040]'s global object[p1033]'s associated `Document`[p894].

5. Assert: this step is never reached, because one of the previous conditions is true. Really?

Both implied event loop[p1073] and implied document[p1073] are vaguely-defined and have a lot of action-at-a-distance. The hope is to remove these, especially implied document[p1073]. See issue #4980.

8.1.7.3 Processing model §[p1074]

An event loop[p1071] must continually run through the following steps for as long as it exists:

1. Let *oldestTask* and *taskStartTime* be null.
2. If the event loop[p1071] has a task queue[p1071] with at least one runnable[p1072] task[p1071], then:
    1. Let *taskQueue* be one such task queue[p1071], chosen in an implementation-defined manner.

    Note

    Remember that the microtask queue[p1072] is not a task queue[p1071], so it will not be chosen in this step. However, a task queue[p1071] to which the microtask task source[p1073] is associated might be chosen in this step. In that case, the task[p1071] chosen in the next step was originally a microtask[p1072], but it got moved as part of spinning the event loop[p1078].

    2. Set *taskStartTime* to the unsafe shared current time.
    3. Set *oldestTask* to the first runnable[p1072] task[p1071] in *taskQueue*, and remove it from *taskQueue*.
    4. Set the event loop[p1071]'s currently running task[p1072] to *oldestTask*.
    5. Perform *oldestTask*'s steps[p1072].
    6. Set the event loop[p1071]'s currently running task[p1072] back to null.
3. Perform a microtask checkpoint[p1077].
4. Let *hasARenderingOpportunity* be false.
5. Let *now* be the unsafe shared current time. [HRT][p1413]
6. If *oldestTask* is not null, then:
    1. Let *top-level browsing contexts* be an empty set.
    2. For each environment settings object[p1032] *settings* of *oldestTask*'s script evaluation environment settings object set[p1072]:
        1. Let *global* be *settings*'s global object[p1033].
        2. If *global* is not a `Window`[p892] object, then continue.
        3. If *global*'s browsing context[p894] is null, then continue.
        4. Let *tlbc* be *global*'s browsing context[p894]'s top-level browsing context[p964].
        5. If *tlbc* is not null, then append it to *top-level browsing contexts*.
    3. Report long tasks, passing in *taskStartTime*, *now* (the end time of the task), *top-level browsing contexts*, and *oldestTask*.
7. **Update the rendering**: if this is a window event loop[p1071], then:
    1. Let *docs* be all `Document`[p127] objects whose relevant agent[p1029]'s event loop[p1071] is this event loop, sorted arbitrarily except that the following conditions must be met:
        - Any `Document`[p127] *B* whose container document[p955] is *A* must be listed after *A* in the list.
        - If there are two documents *A* and *B* that both have the same non-null container document[p955] *C*, then the order of *A* and *B* in the list must match the shadow-including tree order of their respective navigable containers[p955] in *C*'s node tree.

    In the steps below that iterate over *docs*, each `Document`[p127] must be processed in the order it is found in the list.

2. *Rendering opportunities*: Remove from *docs* all Document[p127] objects whose node navigables[p953] do not have a rendering opportunity[p1075].

   A navigable[p952] has a **rendering opportunity** if the user agent is currently able to present the contents of the navigable[p952] to the user, accounting for hardware refresh rate constraints and user agent throttling for performance reasons, but considering content presentable even if it's outside the viewport.

   A navigable[p952] has no rendering opportunities[p1075] if its active document[p952] is render-blocked[p131]; otherwise, rendering opportunities[p1075] are determined based on hardware constraints such as display refresh rates and other factors such as page performance or whether the document's visibility state[p807] is "`visible`". Rendering opportunities typically occur at regular intervals.

   Note

   This specification does not mandate any particular model for selecting rendering opportunities. But for example, if the browser is attempting to achieve a 60Hz refresh rate, then rendering opportunities occur at a maximum of every 60th of a second (about 16.7ms). If the browser finds that a navigable[p952] is not able to sustain this rate, it might drop to a more sustainable 30 rendering opportunities per second for that navigable[p952], rather than occasionally dropping frames. Similarly, if a navigable[p952] is not visible, the user agent might decide to drop that page to a much slower 4 rendering opportunities per second, or even less.

3. If *docs* is not empty, then set *hasARenderingOpportunity* to true and set this event loop[p1071]'s last render opportunity time[p1072] to *taskStartTime*.

4. *Unnecessary rendering*: Remove from *docs* all Document[p127] objects which meet both of the following conditions:

   - the user agent believes that updating the rendering of the Document[p127]'s node navigable[p953] would have no visible effect, and
   - the Document[p127]'s map of animation frame callbacks[p1126] is empty.

5. Remove from *docs* all Document[p127] objects for which the user agent believes that it's preferable to skip updating the rendering for other reasons.

   Note

   The step labeled Rendering opportunities *prevents the user agent from updating the rendering when it is unable to present new content to the user (there's no rendering opportunity[p1075]).*

   The step labeled Unnecessary rendering *prevents the user agent from updating the rendering when there's no new content to draw.*

   This step enables the user agent to prevent the steps below from running for other reasons, for example, to ensure certain tasks[p1071] are executed immediately after each other, with only microtask checkpoints[p1077] interleaved (and without, e.g., animation frame callbacks[p1126] interleaved). Concretely, a user agent might wish to coalesce timer callbacks together, with no intermediate rendering updates.

6. For each fully active[p966] Document[p127] in *docs*, flush autofocus candidates[p829] for that Document[p127] if its node navigable[p953] is a top-level traversable[p953].

7. For each fully active[p966] Document[p127] in *docs*, run the resize steps for that Document[p127]. [CSSOMVIEW][p1412]

8. For each fully active[p966] Document[p127] in *docs*, run the scroll steps for that Document[p127]. [CSSOMVIEW][p1412]

9. For each fully active[p966] Document[p127] in *docs*, evaluate media queries and report changes for that Document[p127]. [CSSOMVIEW][p1412]

10. For each fully active[p966] Document[p127] in *docs*, update animations and send events for that Document[p127], passing in *now* as the timestamp. [WEBANIMATIONS][p1418]

11. For each fully active[p966] Document[p127] in *docs*, run the fullscreen steps for that Document[p127]. [FULLSCREEN][p1413]

12. For each fully active[p966] Document[p127] in *docs*, if the user agent detects that the backing storage associated with a CanvasRenderingContext2D[p666] or an OffscreenCanvasRenderingContext2D[p729], *context*, has been lost, then it must run the **context lost steps** for each such *context*:

    1. Let *canvas* be the value of *context*'s canvas[p673] attribute, if *context* is a CanvasRenderingContext2D[p666], or the associated OffscreenCanvas object[p730] for *context* otherwise.

    2. Set *context*'s context lost[p674] to true.

3. Reset the rendering context to its default state[p674] given *context*.
4. Let *shouldRestore* be the result of firing an event named `contextlost`[p1406] at *canvas*, with the `cancelable` attribute initialized to true.
5. If *shouldRestore* is false, then abort these steps.
6. Attempt to restore *context* by creating a backing storage using *context*'s attributes and associating them with *context*. If this fails, then abort these steps.
7. Set *context*'s context lost[p674] to false.
8. Fire an event named `contextrestored`[p1406] at *canvas*.

13. For each fully active[p966] `Document`[p127] in *docs*, run the animation frame callbacks[p1126] for that `Document`[p127], passing in *now* as the timestamp.
14. For each fully active[p966] `Document`[p127] *doc* in *docs*:
    1. Recalculate styles and update layout for *doc*.
    2. Let *depth* be 0.
    3. Gather active resize observations at depth *depth* for *doc*.
    4. While *doc* has active resize observations:
        1. Set *depth* to the result of broadcasting active resize observations given *doc*.
        2. Recalculate styles and update layout for *doc*.
        3. Gather active resize observations at depth *depth* for *doc*.
    5. If *doc* has skipped resize observations, then deliver resize loop error given *doc*.
15. For each fully active[p966] `Document`[p127] in *docs*, if the focused area[p817] of that `Document`[p127] is not a focusable area[p815], then run the focusing steps[p822] for that `Document`[p127]'s viewport, and set the `Document`[p127]'s relevant global object[p1039]'s navigation API[p922]'s focus changed during ongoing navigation[p934] to false.

    Example

    For example, this might happen because an element has the `hidden`[p805] attribute added, causing it to stop being rendered[p1325]. It might also happen to an `input`[p512] element when the element gets disabled[p592].

    Note

    This will usually[p824] fire `blur`[p1406] events, and possibly `change`[p1406] events.

    Note

    In addition to this asynchronous fixup, if the focused area of the document[p817] is removed, there is a synchronous fixup[p46]. That one will not *fire `blur`[p1406] or `change`[p1406] events.*

16. For each fully active[p966] `Document`[p127] in *docs*, run the update intersection observations steps for that `Document`[p127], passing in *now* as the timestamp. [INTERSECTIONOBSERVER][p1413]
17. Invoke the mark paint timing algorithm for each `Document`[p127] object in *docs*.
18. For each fully active[p966] `Document`[p127] in *docs*, update the rendering or user interface of that `Document`[p127] and its node navigable[p953] to reflect the current state.
19. For each fully active[p966] `Document`[p127] *doc* in *docs* run process top layer removals given *doc*.

8. If all of the following are true
    - this is a window event loop[p1071]
    - there is no task[p1071] in this event loop[p1071]'s task queues[p1071] whose document[p1072] is fully active[p966]
    - this event loop[p1071]'s microtask queue[p1072] is empty
    - *hasARenderingOpportunity* is false

    then:

1. Set this event loop[p1071]'s last idle period start time[p1072] to the unsafe shared current time.
2. Let *computeDeadline* be the following steps:
    1. Let *deadline* be this event loop[p1071]'s last idle period start time[p1072] plus 50.

    Note

    The cap of 50ms in the future is to ensure responsiveness to new user input within the threshold of human perception.

    2. Let *hasPendingRenders* be false.
    3. For each *windowInSameLoop* of the same-loop windows[p1072] for this event loop[p1071]:
        1. If *windowInSameLoop*'s map of animation frame callbacks[p1126] is not empty, or if the user agent believes that the *windowInSameLoop* might have pending rendering updates, set *hasPendingRenders* to true.
        2. Let *timerCallbackEstimates* be the result of getting the values of *windowInSameLoop*'s map of active timers[p1101].
        3. For each *timeoutDeadline* of *timerCallbackEstimates*, if *timeoutDeadline* is less than *deadline*, set *deadline* to *timeoutDeadline*.
    4. If *hasPendingRenders* is true, then:
        1. Let *nextRenderDeadline* be this event loop[p1071]'s last render opportunity time[p1072] plus (1000 divided by the current refresh rate).

        The refresh rate can be hardware- or implementation-specific. For a refresh rate of 60Hz, the *nextRenderDeadline* would be about 16.67ms after the last render opportunity time[p1072].

        2. If *nextRenderDeadline* is less than *deadline*, then return *nextRenderDeadline*.
    5. Return *deadline*.
3. For each *win* of the same-loop windows[p1072] for this event loop[p1071], perform the start an idle period algorithm for *win* with the following step: return the result of calling *computeDeadline*, coarsened given *win*'s relevant settings object[p1039]'s cross-origin isolated capability[p1032]. [REQUESTIDLECALLBACK][p1416]

9. If this is a worker event loop[p1071], then:
    1. If this event loop[p1071]'s agent's single realm's global object[p1033] is a supported[p1126] `DedicatedWorkerGlobalScope`[p1168] and the user agent believes that it would benefit from having its rendering updated at this time, then:
        1. Let *now* be the current high resolution time given the `DedicatedWorkerGlobalScope`[p1168]. [HRT][p1413]
        2. Run the animation frame callbacks[p1126] for that `DedicatedWorkerGlobalScope`[p1168], passing in *now* as the timestamp.
        3. Update the rendering of that dedicated worker to reflect the current state.

    Note

    Similar to the notes for updating the rendering[p1074] in a window event loop[p1071], a user agent can determine the rate of rendering in the dedicated worker.

    2. If there are no tasks[p1071] in the event loop[p1071]'s task queues[p1071] and the `WorkerGlobalScope`[p1166] object's closing[p1169] flag is true, then destroy the event loop[p1071], aborting these steps, resuming the run a worker[p1170] steps described in the Web workers[p1150] section below.

When a user agent is to **perform a microtask checkpoint**:

1. If the event loop[p1071]'s performing a microtask checkpoint[p1072] is true, then return.
2. Set the event loop[p1071]'s performing a microtask checkpoint[p1072] to true.

3. While the event loop[p1071]'s microtask queue[p1072] is not empty:

    1. Let *oldestMicrotask* be the result of dequeuing from the event loop[p1071]'s microtask queue[p1072].

    2. Set the event loop[p1071]'s currently running task[p1072] to *oldestMicrotask*.

    3. Run *oldestMicrotask*.

    > **Note**
    > *This might involve invoking scripted callbacks, which eventually calls the clean up after running script[p1052] steps, which call this perform a microtask checkpoint[p1077] algorithm again, which is why we use the performing a microtask checkpoint[p1072] flag to avoid reentrancy.*

    4. Set the event loop[p1071]'s currently running task[p1072] back to null.

4. For each environment settings object[p1032] whose responsible event loop[p1032] is this event loop[p1071], notify about rejected promises[p1054] on that environment settings object[p1032].

5. Cleanup Indexed Database transactions.

6. Perform ClearKeptObjects().

    > **Note**
    > *When `WeakRef.prototype.deref()` returns an object, that object is kept alive until the next invocation of ClearKeptObjects(), after which it is again subject to garbage collection.*

7. Set the event loop[p1071]'s performing a microtask checkpoint[p1072] to false.

When an algorithm running in parallel[p43] is to **await a stable state**, the user agent must queue a microtask[p1073] that runs the following steps, and must then stop executing (execution of the algorithm resumes when the microtask is run, as described in the following steps):

1. Run the algorithm's **synchronous section**.

2. Resumes execution of the algorithm in parallel[p43], if appropriate, as described in the algorithm's steps.

> **Note**
> *Steps in synchronous sections[p1078] are marked with ⌛.*

Algorithm steps that say to **spin the event loop** until a condition *goal* is met are equivalent to substituting in the following algorithm steps:

1. Let *task* be the event loop[p1071]'s currently running task[p1072].

    > **Note**
    > task *could be a microtask[p1072].*

2. Let *task source* be *task*'s source[p1072].

3. Let *old stack* be a copy of the JavaScript execution context stack.

4. Empty the JavaScript execution context stack.

5. Perform a microtask checkpoint[p1077].

    > **Note**
    > *If* task *is a microtask[p1072] this step will be a no-op due to performing a microtask checkpoint[p1072] being true.*

6. In parallel[p43]:

    1. Wait until the condition *goal* is met.

    2. Queue a task[p1072] on *task source* to:

1. Replace the JavaScript execution context stack with *old stack*.
2. Perform any steps that appear after this spin the event loop[p1078] instance in the original algorithm.

Note

This resumes task.

7. Stop *task*, allowing whatever algorithm that invoked it to resume.

Note

This causes the event loop[p1071]'s main set of steps or the perform a microtask checkpoint[p1077] algorithm to continue.

Note

Unlike other algorithms in this and other specifications, which behave similar to programming-language function calls, spin the event loop[p1078] is more like a macro, which saves typing and indentation at the usage site by expanding into a series of steps and operations.

Example

An algorithm whose steps are:

1. Do something.
2. Spin the event loop[p1078] until awesomeness happens.
3. Do something else.

is a shorthand which, after "macro expansion", becomes

1. Do something.
2. Let *old stack* be a copy of the JavaScript execution context stack.
3. Empty the JavaScript execution context stack.
4. Perform a microtask checkpoint[p1077].
5. In parallel[p43]:
    1. Wait until awesomeness happens.
    2. Queue a task[p1072] on the task source in which "do something" was done to:
        1. Replace the JavaScript execution context stack with *old stack*.
        2. Do something else.

Example

Here is a more full example of the substitution, where the event loop is spun from inside a task that is queued from work in parallel. The version using spin the event loop[p1078]:

1. In parallel[p43]:
    1. Do parallel thing 1.
    2. Queue a task[p1072] on the DOM manipulation task source[p1080] to:
        1. Do task thing 1.
        2. Spin the event loop[p1078] until awesomeness happens.
        3. Do task thing 2.
    3. Do parallel thing 2.

The fully expanded version:

1. In parallel[p43]:
    1. Do parallel thing 1.
    2. Let *old stack* be null.
    3. Queue a task[p1072] on the DOM manipulation task source[p1080] to:
        1. Do task thing 1.
        2. Set *old stack* to a copy of the JavaScript execution context stack.
        3. Empty the JavaScript execution context stack.
        4. Perform a microtask checkpoint[p1077].
    4. Wait until awesomeness happens.
    5. Queue a task[p1072] on the DOM manipulation task source[p1080] to:
        1. Replace the JavaScript execution context stack with *old stack*.
        2. Do task thing 2.
    6. Do parallel thing 2.

Some of the algorithms in this specification, for historical reasons, require the user agent to **pause** while running a task[p1071] until a condition *goal* is met. This means running the following steps:

1. If necessary, update the rendering or user interface of any `Document`[p127] or navigable[p952] to reflect the current state.
2. Wait until the condition *goal* is met. While a user agent has a paused task[p1071], the corresponding event loop[p1071] must not run further tasks[p1071], and any script in the currently running task[p1071] must block. User agents should remain responsive to user input while paused, however, albeit in a reduced capacity since the event loop[p1071] will not be doing anything.

⚠Warning!

Pausing[p1080] is highly detrimental to the user experience, especially in scenarios where a single event loop[p1071] is shared among multiple documents. User agents are encouraged to experiment with alternatives to pausing[p1080], such as spinning the event loop[p1078] or even simply proceeding without any kind of suspended execution at all, insofar as it is possible to do so while preserving compatibility with existing content. This specification will happily change if a less-drastic alternative is discovered to be web-compatible.

In the interim, implementers should be aware that the variety of alternatives that user agents might experiment with can change subtle aspects of event loop[p1071] behavior, including task[p1071] and microtask[p1072] timing. Implementations should continue experimenting even if doing so causes them to violate the exact semantics implied by the pause[p1080] operation.

8.1.7.4 Generic task sources §[p1080]

The following task sources[p1072] are used by a number of mostly unrelated features in this and other specifications.

The *DOM manipulation task source*

This task source[p1072] is used for features that react to DOM manipulations, such as things that happen in a non-blocking fashion when an element is inserted into the document[p46].

The *user interaction task source*

This task source[p1072] is used for features that react to user interaction, for example keyboard or mouse input.

Events sent in response to user input (e.g. `click` events) must be fired using tasks[p1071] queued[p1072] with the user interaction task source[p1080]. [UIEVENTS][p1417]

The *networking task source*

This task source[p1072] is used for features that trigger in response to network activity.

The *navigation and traversal task source*

This task source[p1072] is used to queue tasks involved in navigation[p977] and history traversal[p1002].

8.1.7.5 Dealing with the event loop from other specifications §[p1081]

Writing specifications that correctly interact with the event loop[p1071] can be tricky. This is compounded by how this specification uses concurrency-model-independent terminology, so we say things like "event loop[p1071]" and "in parallel[p43]" instead of using more familiar model-specific terms like "main thread" or "on a background thread".

By default, specification text generally runs on the event loop[p1071]. This falls out from the formal event loop processing model[p1074], in that you can eventually trace most algorithms back to a task[p1071] queued[p1072] there.

Example

The algorithm steps for any JavaScript method will be invoked by author code calling that method. And author code can only be run via queued tasks, usually originating somewhere in the `script` processing model[p645].

From this starting point, the overriding guideline is that any work a specification needs to perform that would otherwise block the event loop[p1071] must instead be performed in parallel[p43] with it. This includes (but is not limited to):

- performing heavy computation;
- displaying a user-facing prompt;
- performing operations which could require involving outside systems (i.e. "going out of process").

The next complication is that, in algorithm sections that are in parallel[p43], you must not create or manipulate objects associated to a specific realm, global[p1033], or environment settings object[p1032]. (Stated in more familiar terms, you must not directly access main-thread artifacts from a background thread.) Doing so would create data races observable to JavaScript code, since after all, your algorithm steps are running *in parallel*[p43] to the JavaScript code.

You can, however, manipulate specification-level data structures and values from *Infra*, as those are realm-agnostic. They are never directly exposed to JavaScript without a specific conversion taking place (often via Web IDL). [INFRA][p1413] [WEBIDL][p1418]

To affect the world of observable JavaScript objects, then, you must queue a global task[p1073] to perform any such manipulations. This ensures your steps are properly interleaved with respect to other things happening on the event loop[p1071]. Furthermore, you must choose a task source[p1072] when queuing a global task[p1073]; this governs the relative order of your steps versus others. If you are unsure which task source[p1072] to use, pick one of the generic task sources[p1080] that sounds most applicable. Finally, you must indicate which global object[p1033] your queued task is associated with; this ensures that if that global object is inactive, the task does not run.

Note

The base primitive, on which queue a global task[p1073] builds, is the queue a task[p1072] algorithm. In general, queue a global task[p1073] is better because it automatically picks the right event loop[p1071] and, where appropriate, document[p1072]. Older specifications often use queue a task[p1072] combined with the implied event loop[p1073] and implied document[p1073] concepts, but this is discouraged.

Putting this all together, we can provide a template for a typical algorithm that needs to do work asynchronously:

1. Do any synchronous setup work, while still on the event loop[p1071]. This may include converting realm-specific JavaScript values into realm-agnostic specification-level values.
2. Perform a set of potentially-expensive steps in parallel[p43], operating entirely on realm-agnostic values, and producing a realm-agnostic result.
3. Queue a global task[p1073], on a specified task source[p1072] and given an appropriate global object[p1033], to convert the realm-agnostic result back into observable effects on the observable world of JavaScript objects on the event loop[p1071].

Example

The following is an algorithm that "encrypts" a passed-in list of scalar value strings *input*, after parsing them as URLs:

1. Let *urls* be an empty list.
2. For each *string* of *input*:
    1. Let *parsed* be the result of parsing[p95] *string* relative to the current settings object[p1038].
    2. If *parsed* is failure, then return a promise rejected with a "`SyntaxError`" `DOMException`.
    3. Let *serialized* be the result of applying the URL serializer to *parsed*.
    4. Append *serialized* to *urls*.
3. Let *realm* be the current realm.
4. Let *p* be a new promise.
5. Run the following steps in parallel[p43]:
    1. Let *encryptedURLs* be an empty list.
    2. For each *url* of *urls*:
        1. Wait 100 milliseconds, so that people think we're doing heavy-duty encryption.
        2. Let *encrypted* be a new string derived from *url*, whose *n*th code unit is equal to *url*'s *n*th code unit plus 13.
        3. Append *encrypted* to *encryptedURLs*.
    3. Queue a global task[p1073] on the networking task source[p1081], given *realm*'s global object[p1033], to perform the following steps:
        1. Let *array* be the result of converting *encryptedURLs* to a JavaScript array, in *realm*.
        2. Resolve *p* with *array*.
6. Return *p*.

Here are several things to notice about this algorithm:

- It does its URL parsing up front, on the event loop[p1071], before going to the in parallel[p43] steps. This is necessary, since parsing depends on the current settings object[p1038], which would no longer be current after going in parallel[p43].
- Alternately, it could have saved a reference to the current settings object[p1038]'s API base URL[p1032] and used it during the in parallel[p43] steps; that would have been equivalent. However, we recommend instead doing as much work as possible up front, as this example does. Attempting to save the correct values can be error prone; for example, if we'd saved just the current settings object[p1038], instead of its API base URL[p1032], there would have been a potential race.
- It implicitly passes a list of strings from the initial steps to the in parallel[p43] steps. This is OK, as both lists and strings are realm-agnostic.
- It performs "expensive computation" (waiting for 100 milliseconds per input URL) during the in parallel[p43] steps, thus not blocking the main event loop[p1071].
- Promises, as observable JavaScript objects, are never created and manipulated during the in parallel[p43] steps. *p* is created before entering those steps, and then is manipulated during a task[p1071] that is queued[p1073] specifically for that purpose.
- The creation of a JavaScript array object also happens during the queued task, and is careful to specify which realm it creates the array in since that is no longer obvious from context.

(On these last two points, see also whatwg/webidl issue #135 and whatwg/webidl issue #371, where we are still mulling over the subtleties of the above promise-resolution pattern.)

Another thing to note is that, in the event this algorithm was called from a Web IDL-specified operation taking a `sequence<USVString>`, there was an automatic conversion from realm-specific JavaScript objects provided by the author as input, into the realm-agnostic `sequence<USVString>` Web IDL type, which we then treat as a list of scalar value strings. So depending on

how your specification is structured, there may be other implicit steps happening on the main event loop[p1071] that play a part in this whole process of getting you ready to go in parallel[p43].

8.1.8 Events §[p1083]

MDN

8.1.8.1 Event handlers §[p1083]

Many objects can have **event handlers** specified. These act as non-capture event listeners for the object on which they are specified. [DOM][p1412]

An event handler[p1083] is a struct with two items:

- a **value**, which is either null, a callback object, or an internal raw uncompiled handler[p1088]. The `EventHandler`[p1087] callback function type describes how this is exposed to scripts. Initially, an event handler[p1083]'s value[p1083] must be set to null.
- a **listener**, which is either null or an event listener responsible for running the event handler processing algorithm[p1086]. Initially, an event handler[p1083]'s listener[p1083] must be set to null.

Event handlers are exposed in two ways.

The first way, common to all event handlers, is as an event handler IDL attribute[p1084].

The second way is as an event handler content attribute[p1084]. Event handlers on HTML elements[p45] and some of the event handlers on `Window`[p892] objects are exposed in this way.

For both of these two ways, the event handler[p1083] is exposed through a **name**, which is a string that always starts with "`on`" and is followed by the name of the event for which the handler is intended.

Most of the time, the object that exposes an event handler[p1083] is the same as the object on which the corresponding event listener is added. However, the `body`[p199] and `frameset`[p1369] elements expose several event handlers[p1083] that act upon the element's `Window`[p892] object, if one exists. In either case, we call the object an event handler[p1083] acts upon the **target** of that event handler[p1083].

To **determine the target of an event handler**, given an `EventTarget` object *eventTarget* on which the event handler[p1083] is exposed, and an event handler name[p1083] *name*, the following steps are taken:

1. If *eventTarget* is not a `body`[p199] element or a `frameset`[p1369] element, then return *eventTarget*.
2. If *name* is not the name of an attribute member of the `WindowEventHandlers`[p1093] interface mixin and the `Window`-reflecting body element event handler set[p1091] does not contain *name*, then return *eventTarget*.
3. If *eventTarget*'s node document is not an active document[p961], then return null.

   Note

   This could happen if this object is a `body`[p199] element without a corresponding `Window`[p892] object, for example.

   Note

   This check does not necessarily prevent `body`[p199] and `frameset`[p1369] elements that are not the body element[p133] of their node document from reaching the next step. In particular, a `body`[p199] element created in an active document[p961] (perhaps with `document.createElement()`) but not connected will also have its corresponding `Window`[p892] object as the target[p1083] of several event handlers[p1083] exposed through it.

4. Return *eventTarget*'s node document's relevant global object[p1039].

Each `EventTarget` object that has one or more event handlers[p1083] specified has an associated **event handler map**, which is a map of strings representing names[p1083] of event handlers[p1083] to event handlers[p1083].

When an `EventTarget` object that has one or more event handlers[p1083] specified is created, its event handler map[p1083] must be initialized such that it contains an entry for each event handler[p1083] that has that object as target[p1083], with items in those event

handlers[p1083] set to their initial values.

Note

The order of the entries of event handler map[p1083] could be arbitrary. It is not observable through any algorithms that operate on the map.

Note

Entries are not created in the event handler map[p1083] of an object for event handlers[p1083] that are merely exposed on that object, but have some other object as their targets[p1083].

An **event handler IDL attribute** is an IDL attribute for a specific event handler[p1083]. The name of the IDL attribute is the same as the name[p1083] of the event handler[p1083].

The getter of an event handler IDL attribute[p1084] with name *name*, when called, must run these steps:

1. Let *eventTarget* be the result of determining the target of an event handler[p1083] given this object and *name*.
2. If *eventTarget* is null, then return null.
3. Return the result of getting the current value of the event handler[p1088] given *eventTarget* and *name*.

The setter of an event handler IDL attribute[p1084] with name *name*, when called, must run these steps:

1. Let *eventTarget* be the result of determining the target of an event handler[p1083] given this object and *name*.
2. If *eventTarget* is null, then return.
3. If the given value is null, then deactivate an event handler[p1085] given *eventTarget* and *name*.
4. Otherwise:
    1. Let *handlerMap* be *eventTarget*'s event handler map[p1083].
    2. Let *eventHandler* be *handlerMap*[*name*].
    3. Set *eventHandler*'s value[p1083] to the given value.
    4. Activate an event handler[p1085] given *eventTarget* and *name*.

Note

Certain event handler IDL attributes[p1084] have additional requirements, in particular the `onmessage`[p1146] attribute of `MessagePort`[p1144] objects.

An **event handler content attribute** is a content attribute for a specific event handler[p1083]. The name of the content attribute is the same as the name[p1083] of the event handler[p1083].

Event handler content attributes[p1084], when specified, must contain valid JavaScript code which, when parsed, would match the *FunctionBody* production after automatic semicolon insertion.

The following attribute change steps are used to synchronize between event handler content attributes[p1084] and event handlers[p1083]: [DOM][p1412]

1. If *namespace* is not null, or *localName* is not the name of an event handler content attribute[p1084] on *element*, then return.
2. Let *eventTarget* be the result of determining the target of an event handler[p1083] given *element* and *localName*.
3. If *eventTarget* is null, then return.
4. If *value* is null, then deactivate an event handler[p1085] given *eventTarget* and *localName*.
5. Otherwise:
    1. If the Should element's inline behavior be blocked by Content Security Policy? algorithm returns "`Blocked`" when

executed upon *element*, "`script attribute`", and *value*, then return. [CSP][p1411]

2. Let *handlerMap* be *eventTarget*'s event handler map[p1083].
3. Let *eventHandler* be *handlerMap*[*localName*].
4. Let *location* be the script location that triggered the execution of these steps.
5. Set *eventHandler*'s value[p1083] to the internal raw uncompiled handler[p1088] *value*/*location*.
6. Activate an event handler[p1085] given *eventTarget* and *localName*.

Note

Per the DOM Standard, these steps are run even if oldValue *and* value *are identical (setting an attribute to its current value), but* not *if* oldValue *and* value *are both null (removing an attribute that doesn't currently exist). [DOM][p1412]*

To **deactivate an event handler** given an `EventTarget` object *eventTarget* and a string *name* that is the name[p1083] of an event handler[p1083], run these steps:

1. Let *handlerMap* be *eventTarget*'s event handler map[p1083].
2. Let *eventHandler* be *handlerMap*[*name*].
3. Set *eventHandler*'s value[p1083] to null.
4. Let *listener* be *eventHandler*'s listener[p1083].
5. If *listener* is not null, then remove an event listener with *eventTarget* and *listener*.
6. Set *eventHandler*'s listener[p1083] to null.

To **erase all event listeners and handlers** given an `EventTarget` object *eventTarget*, run these steps:

1. If *eventTarget* has an associated event handler map[p1083], then for each *name* → *eventHandler* of *eventTarget*'s associated event handler map[p1083], deactivate an event handler[p1085] given *eventTarget* and *name*.
2. Remove all event listeners given *eventTarget*.

Note

This algorithm is used to define `document.open()`[p1098].

To **activate an event handler** given an `EventTarget` object *eventTarget* and a string *name* that is the name[p1083] of an event handler[p1083], run these steps:

1. Let *handlerMap* be *eventTarget*'s event handler map[p1083].
2. Let *eventHandler* be *handlerMap*[*name*].
3. If *eventHandler*'s listener[p1083] is not null, then return.
4. Let *callback* be the result of creating a Web IDL `EventListener` instance representing a reference to a function of one argument that executes the steps of the event handler processing algorithm[p1086], given *eventTarget*, *name*, and its argument.

   The `EventListener`'s callback context can be arbitrary; it does not impact the steps of the event handler processing algorithm[p1086]. [DOM][p1412]

   Note

   The callback is emphatically not *the event handler[p1083] itself. Every event handler ends up registering the same callback, the algorithm defined below, which takes care of invoking the right code, and processing the code's return value.*

5. Let *listener* be a new event listener whose type is the **event handler event type** corresponding to *eventHandler* and callback is *callback*.

Note

To be clear, an event listener is different from an `EventListener`*.*

6. Add an event listener with *eventTarget* and *listener*.

7. Set *eventHandler*'s listener[p1083] to *listener*.

Note

The event listener registration happens only if the event handler[p1083]'s value[p1083] is being set to non-null, and the event handler[p1083] is not already activated. Since listeners are called in the order they were registered, assuming no deactivation[p1085] occurred, the order of event listeners for a particular event type will always be:

1. *the event listeners registered with* `addEventListener()` *before the first time the event handler[p1083]'s value[p1083] was set to non-null*

2. *then the callback to which it is currently set, if any*

3. *and finally the event listeners registered with* `addEventListener()` *after the first time the event handler[p1083]'s value[p1083] was set to non-null.*

Example

This example demonstrates the order in which event listeners are invoked. If the button in this example is clicked by the user, the page will show four alerts, with the text "ONE", "TWO", "THREE", and "FOUR" respectively.

```
<button id="test">Start Demo</button>
<script>
 var button = document.getElementById('test');
 button.addEventListener('click', function () { alert('ONE') }, false);
 button.setAttribute('onclick', "alert('NOT CALLED')"); // event handler listener is registered
here
 button.addEventListener('click', function () { alert('THREE') }, false);
 button.onclick = function () { alert('TWO'); };
 button.addEventListener('click', function () { alert('FOUR') }, false);
</script>
```

However, in the following example, the event handler is deactivated[p1085] after its initial activation (and its event listener is removed), before being reactivated at a later time. The page will show five alerts with "ONE", "TWO", "THREE", "FOUR", and "FIVE" respectively, in order.

```
<button id="test">Start Demo</button>
<script>
 var button = document.getElementById('test');
 button.addEventListener('click', function () { alert('ONE') }, false);
 button.setAttribute('onclick', "alert('NOT CALLED')"); // event handler is activated here
 button.addEventListener('click', function () { alert('TWO') }, false);
 button.onclick = null;                                 // but deactivated here
 button.addEventListener('click', function () { alert('THREE') }, false);
 button.onclick = function () { alert('FOUR'); };       // and re-activated here
 button.addEventListener('click', function () { alert('FIVE') }, false);
</script>
```

Note

The interfaces implemented by the event object do not influence whether an event handler[p1083] is triggered or not.

The event handler processing algorithm for an `EventTarget` object *eventTarget*, a string *name* representing the name[p1083] of an event handler[p1083], and an `Event` object *event* is as follows:

1. Let *callback* be the result of getting the current value of the event handler[p1088] given *eventTarget* and *name*.

2. If *callback* is null, then return.

3. Let *special error event handling* be true if *event* is an ErrorEvent[p1054] object, *event*'s type is "error[p1406]", and *event*'s currentTarget implements the WindowOrWorkerGlobalScope[p1094] mixin. Otherwise, let *special error event handling* be false.

4. Process the Event object *event* as follows:

   ↪ **If *special error event handling* is true**

   Invoke *callback* with five arguments, the first one having the value of *event*'s message[p1054] attribute, the second having the value of *event*'s filename[p1054] attribute, the third having the value of *event*'s lineno[p1054] attribute, the fourth having the value of *event*'s colno[p1054] attribute, the fifth having the value of *event*'s error[p1054] attribute, and with the *callback this value* set to *event*'s currentTarget. Let *return value* be the callback's return value. [WEBIDL][p1418]

   ↪ **Otherwise**

   Invoke *callback* with one argument, the value of which is the Event object *event*, with the *callback this value* set to *event*'s currentTarget. Let *return value* be the callback's return value. [WEBIDL][p1418]

   If an exception gets thrown by the callback, end these steps and allow the exception to propagate. (It will propagate to the DOM event dispatch logic, which will then report the exception[p1053].)

5. Process *return value* as follows:

   ↪ **If *event* is a BeforeUnloadEvent[p951] object and *event*'s type is "beforeunload[p1406]"**

   Note

   In this case, the event handler IDL attribute[p1084]'s type will be OnBeforeUnloadEventHandler[p1088], so return value *will have been coerced into either null or a DOMString.*

   If *return value* is not null, then:

   1. Set *event*'s canceled flag.
   2. If *event*'s returnValue[p951] attribute's value is the empty string, then set *event*'s returnValue[p951] attribute's value to *return value*.

   ↪ **If *special error event handling* is true**

   If *return value* is true, then set *event*'s canceled flag.

   ↪ **Otherwise**

   If *return value* is false, then set *event*'s canceled flag.

   Note

   If we've gotten to this "Otherwise" clause because event's type *is* "beforeunload[p1406]" *but* event *is* not *a* BeforeUnloadEvent[p951] *object, then* return value *will never be false, since in such cases* return value *will have been coerced into either null or a DOMString.*

The EventHandler[p1087] callback function type represents a callback used for event handlers. It is represented in Web IDL as follows:

IDL

```
[LegacyTreatNonObjectAsNull]
callback EventHandlerNonNull = any (Event event);
typedef EventHandlerNonNull? EventHandler;
```

Note

In JavaScript, any Function object implements this interface.

Example

For example, the following document fragment:

```
<body onload="alert(this)" onclick="alert(this)">
```

...leads to an alert saying "`[object Window]`" when the document is loaded, and an alert saying "`[object HTMLBodyElement]`" whenever the user clicks something in the page.

Note

The return value of the function affects whether the event is canceled or not: as described above, if the return value is false, the event is canceled.

There are two exceptions in the platform, for historical reasons:

- *The* onerror[p1091] *handlers on global objects, where returning* true *cancels the event.*
- *The* onbeforeunload[p1092] *handler, where returning any non-null and non-undefined value will cancel the event.*

For historical reasons, the onerror[p1091] handler has different arguments:

IDL

```
[LegacyTreatNonObjectAsNull]
callback OnErrorEventHandlerNonNull = any ((Event or DOMString) event, optional DOMString source,
optional unsigned long lineno, optional unsigned long colno, optional any error);
typedef OnErrorEventHandlerNonNull? OnErrorEventHandler;
```

Example

```
window.onerror = (message, source, lineno, colno, error) => { … };
```

Similarly, the onbeforeunload[p1092] handler has a different return value:

IDL

```
[LegacyTreatNonObjectAsNull]
callback OnBeforeUnloadEventHandlerNonNull = DOMString? (Event event);
typedef OnBeforeUnloadEventHandlerNonNull? OnBeforeUnloadEventHandler;
```

An **internal raw uncompiled handler** is a tuple with the following information:

- An uncompiled script body
- A location where the script body originated, in case an error needs to be reported

When the user agent is to **get the current value of the event handler** given an EventTarget object *eventTarget* and a string *name* that is the name[p1083] of an event handler[p1083], it must run these steps:

1. Let *handlerMap* be *eventTarget*'s event handler map[p1083].
2. Let *eventHandler* be *handlerMap*[*name*].
3. If *eventHandler*'s value[p1083] is an internal raw uncompiled handler[p1088], then:
    1. If *eventTarget* is an element, then let *element* be *eventTarget*, and *document* be *element*'s node document. Otherwise, *eventTarget* is a Window[p892] object, let *element* be null, and *document* be *eventTarget*'s associated Document[p894].
    2. If scripting is disabled[p1039] for *document*, then return null.
    3. Let *body* be the uncompiled script body in *eventHandler*'s value[p1083].
    4. Let *location* be the location where the script body originated, as given by *eventHandler*'s value[p1083].
    5. If *element* is not null and *element* has a form owner[p588], let *form owner* be that form owner[p588]. Otherwise, let *form owner* be null.
    6. Let *settings object* be the relevant settings object[p1039] of *document*.
    7. If *body* is not parsable as *FunctionBody* or if parsing detects an early error, then follow these substeps:

1. Set *eventHandler*'s value[p1083] to null.

   Note

   This does not deactivate[p1085] the event handler, which additionally removes the event handler's listener[p1083] (if present).

2. Report the error[p1053] for the appropriate script[p1040] and with the appropriate position (line number and column number) given by *location*, using *settings object*'s global object[p1033]. If the error is still *not handled*[p1053] after this, then the error may be reported to a developer console.

3. Return null.

8. Push *settings object*'s realm execution context[p1032] onto the JavaScript execution context stack; it is now the running JavaScript execution context.

   Note

   This is necessary so the subsequent invocation of OrdinaryFunctionCreate takes place in the correct realm.

9. Let *function* be the result of calling OrdinaryFunctionCreate, with arguments:

   functionPrototype

   %Function.prototype%

   sourceText

   ↪ **If *name* is `onerror`[p1091] and *eventTarget* is a `Window`[p892] object**

   The string formed by concatenating "`function `", *name*, "`(event, source, lineno, colno, error) {`", U+000A LF, *body*, U+000A LF, and "`}`".

   ↪ **Otherwise**

   The string formed by concatenating "`function `", *name*, "`(event) {`", U+000A LF, *body*, U+000A LF, and "`}`".

   ParameterList

   ↪ **If *name* is `onerror`[p1091] and *eventTarget* is a `Window`[p892] object**

   Let the function have five arguments, named `event`, `source`, `lineno`, `colno`, and `error`.

   ↪ **Otherwise**

   Let the function have a single argument called `event`.

   body

   The result of parsing *body* above.

   thisMode

   non-lexical-this

   scope

   1. Let *realm* be *settings object*'s realm[p1033].

   2. Let *scope* be *realm*.[[GlobalEnv]].

   3. If *eventHandler* is an element's event handler[p1083], then set *scope* to NewObjectEnvironment(*document*, true, *scope*).

      (Otherwise, *eventHandler* is a `Window`[p892] object's event handler[p1083].)

   4. If *form owner* is not null, then set *scope* to NewObjectEnvironment(*form owner*, true, *scope*).

   5. If *element* is not null, then set *scope* to NewObjectEnvironment(*element*, true, *scope*).

   6. Return *scope*.

10. Remove *settings object*'s realm execution context[p1032] from the JavaScript execution context stack.

11. Set *function*.[[ScriptOrModule]] to null.

    Note

    This is done because the default behavior, of associating the created function with the nearest script[p1040] on

the stack, can lead to path-dependent results. For example, an event handler which is first invoked by user interaction would end up with null [[ScriptOrModule]] (since then this algorithm would be first invoked when the active script[p1041] is null), whereas one that is first invoked by dispatching an event from script would have its [[ScriptOrModule]] set to that script.

Instead, we just always set [[ScriptOrModule]] to null. This is more intuitive anyway; the idea that the first script which dispatches an event is somehow responsible for the event handler code is dubious.

In practice, this only affects the resolution of relative URLs via `import()`, which consult the base URL[p1040] of the associated script. Nulling out [[ScriptOrModule]] means that HostLoadImportedModule[p1069] will fall back to the current settings object[p1038]'s API base URL[p1032].

12. Set *eventHandler*'s value[p1083] to the result of creating a Web IDL EventHandler[p1087] callback function object whose object reference is *function* and whose callback context is *settings object*.

4. Return *eventHandler*'s value[p1083].

8.1.8.2 Event handlers on elements, Document[p127] objects, and Window[p892] objects §[p1090]

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported by all HTML elements[p45], as both event handler content attributes[p1084] and event handler IDL attributes[p1084]; and that must be supported by all Document[p127] and Window[p892] objects, as event handler IDL attributes[p1084]:

Event handler[p1083]	Event handler event type[p1085]
onabort	abort
onauxclick	auxclick
onbeforeinput	beforeinput
onbeforematch	beforematch[p1406]
onbeforetoggle	beforetoggle[p1406]
oncancel	cancel[p1406]
oncanplay	canplay[p459]
oncanplaythrough	canplaythrough[p459]
onchange	change[p1406]
onclick	click
onclose	close[p1406]
oncontextlost	contextlost[p1406]
oncontextmenu	contextmenu
oncontextrestored	contextrestored[p1406]
oncopy	copy
oncuechange	cuechange[p460]
oncut	cut
ondblclick	dblclick
ondrag	drag[p856]
ondragend	dragend[p856]
ondragenter	dragenter[p856]
ondragleave	dragleave[p856]
ondragover	dragover[p856]
ondragstart	dragstart[p856]
ondrop	drop[p856]
ondurationchange	durationchange[p459]
onemptied	emptied[p458]
onended	ended[p459]
onformdata	formdata[p1406]
oninput	input
oninvalid	invalid[p1407]
onkeydown	keydown

Event handler[p1083]	Event handler event type[p1085]
onkeypress	keypress
onkeyup	keyup
onloadeddata	loadeddata[p459]
onloadedmetadata	loadedmetadata[p459]
onloadstart	loadstart[p458]
onmousedown	mousedown
onmouseenter	mouseenter
onmouseleave	mouseleave
onmousemove	mousemove
onmouseout	mouseout
onmouseover	mouseover
onmouseup	mouseup
onpaste	paste
onpause	pause[p459]
onplay	play[p459]
onplaying	playing[p459]
onprogress	progress[p458]
onratechange	ratechange[p459]
onreset	reset[p1407]
onsecuritypolicyviolation	securitypolicyviolation
onseeked	seeked[p459]
onseeking	seeking[p459]
onselect	select[p1407]
onslotchange	slotchange
onstalled	stalled[p459]
onsubmit	submit[p1407]
onsuspend	suspend[p458]
ontimeupdate	timeupdate[p459]
ontoggle	toggle[p1407]
onvolumechange	volumechange[p459]
onwaiting	waiting[p459]
onwebkitanimationend	webkitAnimationEnd
onwebkitanimationiteration	webkitAnimationIteration
onwebkitanimationstart	webkitAnimationStart
onwebkittransitionend	webkitTransitionEnd
onwheel	wheel

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported by all HTML elements[p45] other than body[p199] and frameset[p1369] elements, as both event handler content attributes[p1084] and event handler IDL attributes[p1084]; that must be supported by all Document[p127] objects, as event handler IDL attributes[p1084]; and that must be supported by all Window[p892] objects, as event handler IDL attributes[p1084] on the Window[p892] objects themselves, and with corresponding event handler content attributes[p1084] and event handler IDL attributes[p1084] exposed on all body[p199] and frameset[p1369] elements that are owned by that Window[p892] object's associated Document[p894]:

Event handler[p1083]	Event handler event type[p1085]
onblur	blur[p1406]
onerror	error[p1406]
onfocus	focus[p1406]
onload	load[p1407]
onresize	resize
onscroll	scroll
onscrollend	scrollend

We call the set of the names[p1083] of the event handlers[p1083] listed in the first column of this table the **Window-reflecting body element event handler set**.

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported by Window[p892] objects, as event handler IDL attributes[p1084] on the Window[p892] objects themselves, and with corresponding event handler content attributes[p1084] and event handler IDL attributes[p1084] exposed on all body[p199] and frameset[p1369] elements that are owned by that Window[p892] object's associated Document[p894]:

Event handler[p1083]	Event handler event type[p1085]
onafterprint	afterprint[p1406]
onbeforeprint	beforeprint[p1406]
onbeforeunload	beforeunload[p1406]
onhashchange	hashchange[p1406]
onlanguagechange	languagechange[p1407]
onmessage	message[p1407]
onmessageerror	messageerror[p1407]
onoffline	offline[p1407]
ononline	online[p1407]
onpagehide	pagehide[p1407]
onpageshow	pageshow[p1407]
onpopstate	popstate[p1407]
onrejectionhandled	rejectionhandled[p1407]
onstorage	storage[p1407]
onunhandledrejection	unhandledrejection[p1407]
onunload	unload[p1407]

This list of event handlers[p1083] is reified as event handler IDL attributes[p1084] through the WindowEventHandlers[p1093] interface mixin.

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported on Document[p127] objects as event handler IDL attributes[p1084]:

Event handler[p1083]	Event handler event type[p1085]
onreadystatechange	readystatechange[p1407]
onvisibilitychange	visibilitychange[p1407]

8.1.8.2.1 IDL definitions §[p1092]

IDL
```
interface mixin GlobalEventHandlers {
  attribute EventHandler onabort;
  attribute EventHandler onauxclick;
  attribute EventHandler onbeforeinput;
  attribute EventHandler onbeforematch;
  attribute EventHandler onbeforetoggle;
  attribute EventHandler onblur;
  attribute EventHandler oncancel;
  attribute EventHandler oncanplay;
  attribute EventHandler oncanplaythrough;
  attribute EventHandler onchange;
  attribute EventHandler onclick;
  attribute EventHandler onclose;
  attribute EventHandler oncontextlost;
  attribute EventHandler oncontextmenu;
  attribute EventHandler oncontextrestored;
  attribute EventHandler oncopy;
  attribute EventHandler oncuechange;
  attribute EventHandler oncut;
  attribute EventHandler ondblclick;
  attribute EventHandler ondrag;
  attribute EventHandler ondragend;
```

```
  attribute EventHandler ondragenter;
  attribute EventHandler ondragleave;
  attribute EventHandler ondragover;
  attribute EventHandler ondragstart;
  attribute EventHandler ondrop;
  attribute EventHandler ondurationchange;
  attribute EventHandler onemptied;
  attribute EventHandler onended;
  attribute OnErrorEventHandler onerror;

  attribute EventHandler onstorage;
  attribute EventHandler onunhandledrejection;
  attribute EventHandler onunload;
};
```

8.1.8.3 Event firing §p1094

Certain operations and methods are defined as firing events on elements. For example, the `click()`p814 method on the `HTMLElement`p138 interface is defined as firing a `click` event on the element. [UIEVENTS]p1417

Firing a synthetic pointer event named *e* at *target*, with an optional *not trusted flag*, means running these steps:

1. Let *event* be the result of creating an event using `PointerEvent`.
2. Initialize *event*'s `type` attribute to *e*.
3. Initialize *event*'s `bubbles` and `cancelable` attributes to true.
4. Set *event*'s composed flag.
5. If the *not trusted flag* is set, initialize *event*'s `isTrusted` attribute to false.
6. Initialize *event*'s `ctrlKey`, `shiftKey`, `altKey`, and `metaKey` attributes according to the current state of the key input device, if any (false for any keys that are not available).
7. Initialize *event*'s `view` attribute to *target*'s node document's `Window`p892 object, if any, and null otherwise.
8. *event*'s `getModifierState()` method is to return values appropriately describing the current state of the key input device.
9. Return the result of dispatching *event* at *target*.

Firing a `click` event at *target* means firing a synthetic pointer event named `click`p1094 at *target*.

8.2 The `WindowOrWorkerGlobalScope`p1094 mixin §p1094

The `WindowOrWorkerGlobalScope`p1094 mixin is for use of APIs that are to be exposed on `Window`p892 and `WorkerGlobalScope`p1166 objects.

Note

Other standards are encouraged to further extend it using `partial interface mixin WindowOrWorkerGlobalScope`p1094 `{ … };` *along with an appropriate reference.*

IDL

```
typedef (DOMString or Function) TimerHandler;

interface mixin WindowOrWorkerGlobalScope {
  [Replaceable] readonly attribute USVString origin;
  readonly attribute boolean isSecureContext;
  readonly attribute boolean crossOriginIsolated;
```

```
  undefined reportError(any e);

  // base64 utility methods
  DOMString btoa(DOMString data);
  ByteString atob(DOMString data);

  // timers
  long setTimeout(TimerHandler handler, optional long timeout = 0, any... arguments);
  undefined clearTimeout(optional long id = 0);
  long setInterval(TimerHandler handler, optional long timeout = 0, any... arguments);
  undefined clearInterval(optional long id = 0);

  // microtask queuing
  undefined queueMicrotask(VoidFunction callback);

  // ImageBitmap
  Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, optional ImageBitmapOptions options =
{});
  Promise<ImageBitmap> createImageBitmap(ImageBitmapSource image, long sx, long sy, long sw, long sh,
optional ImageBitmapOptions options = {});

  // structured cloning
  any structuredClone(any value, optional StructuredSerializeOptions options = {});
};
Window includes WindowOrWorkerGlobalScope;
WorkerGlobalScope includes WindowOrWorkerGlobalScope;
```

For web developers (non-normative)

self.isSecureContext[p1095]

Returns whether or not this global object represents a secure context[p1039]. [SECURE-CONTEXTS][p1417]

self.origin[p1095]

Returns the global object's origin[p869], serialized as string.

self.crossOriginIsolated[p1095]

Returns whether scripts running in this global are allowed to use APIs that require cross-origin isolation. This depends on the `Cross-Origin-Opener-Policy[p875]` and `Cross-Origin-Embedder-Policy[p883]` HTTP response headers and the "cross-origin-isolated[p72]" feature.

Example

Developers are strongly encouraged to use `self.origin` over `location.origin`. The former returns the origin[p869] of the environment, the latter of the URL of the environment. Imagine the following script executing in a document on `https://stargate.example/`:

```
var frame = document.createElement("iframe")
frame.onload = function() {
  var frameWin = frame.contentWindow
  console.log(frameWin.location.origin) // "null"
  console.log(frameWin.origin) // "https://stargate.example"
}
document.body.appendChild(frame)
```

`self.origin` is a more reliable security indicator.

The **isSecureContext** getter steps are to return true if this's relevant settings object[p1039] is a secure context[p1039], or false otherwise.

The **origin** getter steps are to return this's relevant settings object[p1039]'s origin[p1032], serialized[p869].

The **crossOriginIsolated** getter steps are to return this's relevant settings object[p1039]'s cross-origin isolated capability[p1032].

8.3 Base64 utility methods §[p1096]

The atob()[p1096] and btoa()[p1096] methods allow developers to transform content to and from the base64 encoding.

Note

In these APIs, for mnemonic purposes, the "b" can be considered to stand for "binary", and the "a" for "ASCII". In practice, though, for primarily historical reasons, both the input and output of these functions are Unicode strings.

For web developers (non-normative)

***result* = self.btoa[p1096](*data*)**

Takes the input data, in the form of a Unicode string containing only characters in the range U+0000 to U+00FF, each representing a binary byte with values 0x00 to 0xFF respectively, and converts it to its base64 representation, which it returns.

Throws an "InvalidCharacterError" DOMException exception if the input string contains any out-of-range characters.

***result* = self.atob[p1096](*data*)**

Takes the input data, in the form of a Unicode string containing base64-encoded binary data, decodes it, and returns a string consisting of characters in the range U+0000 to U+00FF, each representing a binary byte with values 0x00 to 0xFF respectively, corresponding to that binary data.

Throws an "InvalidCharacterError" DOMException if the input string is not valid base64 data.

The **btoa(*data*)** method must throw an "InvalidCharacterError" DOMException if *data* contains any character whose code point is greater than U+00FF. Otherwise, the user agent must convert *data* to a byte sequence whose *n*th byte is the eight-bit representation of the *n*th code point of *data*, and then must apply forgiving-base64 encode to that byte sequence and return the result.

The **atob(*data*)** method steps are:

1. Let *decodedData* be the result of running forgiving-base64 decode on *data*.
2. If *decodedData* is failure, then throw an "InvalidCharacterError" DOMException.
3. Return *decodedData*.

8.4 Dynamic markup insertion §[p1096]

Note

APIs for dynamically inserting markup into the document interact with the parser, and thus their behavior varies depending on whether they are used with HTML documents (and the HTML parser[p1210]) or XML documents (and the XML parser[p1321]).

Document[p127] objects have a **throw-on-dynamic-markup-insertion counter**, which is used in conjunction with the create an element for the token[p1258] algorithm to prevent custom element constructors[p742] from being able to use document.open()[p1098], document.close()[p1098], and document.write()[p1099] when they are invoked by the parser. Initially, the counter must be set to zero.

8.4.1 Opening the input stream §[p1096]

For web developers (non-normative)

***document* = *document*.open[p1098]()**

Causes the Document[p127] to be replaced in-place, as if it was a new Document[p127] object, but reusing the previous object, which is then returned.

The resulting Document[p127] has an HTML parser associated with it, which can be given data to parse using document.write()[p1099].

The method has no effect if the Document[p127] is still being parsed.

Throws an "InvalidStateError" DOMException if the Document[p127] is an XML document.

Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor[p742].

***window* = *document*.open[p1098](*url*, *name*, *features*)**

Works like the window.open()[p896] method.

Document[p127] objects have an **active parser was aborted** boolean, which is used to prevent scripts from invoking the document.open()[p1098] and document.write()[p1099] methods (directly or indirectly) after the document's active parser[p131] has been aborted. It is initially false.

The **document open steps**, given a *document*, are as follows:

1. If *document* is an XML document, then throw an "InvalidStateError" DOMException exception.
2. If *document*'s throw-on-dynamic-markup-insertion counter[p1096] is greater than 0, then throw an "InvalidStateError" DOMException.
3. Let *entryDocument* be the entry global object[p1035]'s associated Document[p894].
4. If *document*'s origin is not same origin[p870] to *entryDocument*'s origin, then throw a "SecurityError" DOMException.
5. If *document* has an active parser[p131] whose script nesting level[p1212] is greater than 0, then return *document*.

   Note

   This basically causes document.open()[p1098] to be ignored when it's called in an inline script found during parsing, while still letting it have an effect when called from a non-parser task such as a timer callback or event handler.

6. Similarly, if *document*'s unload counter[p1021] is greater than 0, then return *document*.

   Note

   This basically causes document.open()[p1098] to be ignored when it's called from a beforeunload[p1406], pagehide[p1407], or unload[p1407] event handler while the Document[p127] is being unloaded.

7. If *document*'s active parser was aborted[p1097] is true, then return *document*.

   Note

   This notably causes document.open()[p1098] to be ignored if it is called after a navigation[p977] has started, but only during the initial parse. See issue #4723 for more background.

8. If *document*'s node navigable[p953] is non-null and *document*'s node navigable[p953]'s ongoing navigation[p989] is a navigation ID[p976], then stop loading[p1024] *document*'s node navigable[p953].
9. For each shadow-including inclusive descendant *node* of *document*, erase all event listeners and handlers[p1085] given *node*.
10. If *document* is the associated Document[p894] of *document*'s relevant global object[p1039], then erase all event listeners and handlers[p1085] given *document*'s relevant global object[p1039].
11. Replace all with null within *document*, without firing any mutation events.
12. If *document* is fully active[p966], then:
    1. Let *newURL* be a copy of *entryDocument*'s URL.
    2. If *entryDocument* is not *document*, then set *newURL*'s fragment to null.
    3. Run the URL and history update steps[p991] with *document* and *newURL*.
13. Set *document*'s is initial about:blank[p128] to false.
14. If *document*'s iframe load in progress[p386] flag is set, then set *document*'s mute iframe load[p386] flag.
15. Set *document* to no-quirks mode.
16. Create a new HTML parser[p1210] and associate it with *document*. This is a **script-created parser** (meaning that it can be closed by the document.open()[p1098] and document.close()[p1098] methods, and that the tokenizer will wait for an explicit call to document.close()[p1098] before emitting an end-of-file token). The encoding confidence[p1217] is *irrelevant*.
17. Set the insertion point[p1224] to point at just before the end of the input stream[p1223] (which at this point will be empty).

18. Update the current document readiness[p130] of *document* to "`loading`".

    Note

    This causes a `readystatechange`[p1407] *event to fire, but the event is actually unobservable to author code, because of the previous step which erased all event listeners and handlers*[p1085] *that could observe it.*

19. Return *document*.

Note

The document open steps[p1097] *do not affect whether a* `Document`[p127] *is ready for post-load tasks*[p1297] *or completely loaded*[p1021].

The **`open(unused1, unused2)`** method must return the result of running the document open steps[p1097] with this.

Note

The unused1 *and* unused2 *arguments are ignored, but kept in the IDL to allow code that calls the function with one or two arguments to continue working. They are necessary due to Web IDL overload resolution algorithm rules, which would throw a* `TypeError` *exception for such calls had the arguments not been there. whatwg/webidl issue #581 investigates changing the algorithm to allow for their removal. [WEBIDL]*[p1418]

The **`open(url, name, features)`** method must run these steps:

1. If this is not fully active[p966], then throw an `"InvalidAccessError"` `DOMException` exception.
2. Return the result of running the window open steps[p895] with *url*, *name*, and *features*.

8.4.2 Closing the input stream §[p1098]

For web developers (non-normative)

***document*.close[p1098]()**

Closes the input stream that was opened by the `document.open()`[p1098] method.

Throws an `"InvalidStateError"` `DOMException` if the `Document`[p127] is an XML document.

Throws an `"InvalidStateError"` `DOMException` if the parser is currently executing a custom element constructor[p742].

The **`close()`** method must run the following steps:

1. If this is an XML document, then throw an `"InvalidStateError"` `DOMException`.
2. If this's throw-on-dynamic-markup-insertion counter[p1096] is greater than zero, then throw an `"InvalidStateError"` `DOMException`.
3. If there is no script-created parser[p1097] associated with this, then return.
4. Insert an explicit "EOF" character[p1224] at the end of the parser's input stream[p1223].
5. If this's pending parsing-blocking script[p650] is not null, then return.
6. Run the tokenizer, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the explicit "EOF" character[p1224] or spins the event loop[p1078].

8.4.3 `document.write()`[p1099] §[p1098]

For web developers (non-normative)

***document*.write[p1099](...*text*)**

In general, adds the given string(s) to the `Document`[p127]'s input stream.

⚠Warning!

This method has very idiosyncratic behavior. In some cases, this method can affect the state of the HTML parser[p1210] while the parser is running, resulting in a DOM that does not correspond to the source of the document (e.g. if the string written is the string "<plaintext>" or "<!--"). In other cases, the call can clear the current page first, as if document.open()[p1098] had been called. In yet more cases, the method is simply ignored, or throws an exception. Users agents are explicitly allowed to avoid executing script elements inserted via this method[p1267]. And to make matters even worse, the exact behavior of this method can in some cases be dependent on network latency, which can lead to failures that are very hard to debug. For all these reasons, use of this method is strongly discouraged.

Throws an "InvalidStateError" DOMException when invoked on XML documents.

Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor[p742].

Document[p127] objects have an **ignore-destructive-writes counter**, which is used in conjunction with the processing of script[p638] elements to prevent external scripts from being able to use document.write()[p1099] to blow away the document by implicitly calling document.open()[p1098]. Initially, the counter must be set to zero.

The **document write steps**, given a Document[p127] object *document* and a string *input*, are as follows:

1. If *document* is an XML document, then throw an "InvalidStateError" DOMException.
2. If *document*'s throw-on-dynamic-markup-insertion counter[p1096] is greater than 0, then throw an "InvalidStateError" DOMException.
3. If *document*'s active parser was aborted[p1097] is true, then return.
4. If the insertion point[p1224] is undefined, then:
    1. If *document*'s unload counter[p1021] is greater than 0 or *document*'s ignore-destructive-writes counter[p1099] is greater than 0, then return.
    2. Run the document open steps[p1097] with *document*.
5. Insert *input* into the input stream[p1223] just before the insertion point[p1224].
6. If *document*'s pending parsing-blocking script[p650] is null, then have the HTML parser[p1210] process *input*, one code point at a time, processing resulting tokens as they are emitted, and stopping when the tokenizer reaches the insertion point or when the processing of the tokenizer is aborted by the tree construction stage (this can happen if a script[p638] end tag token is emitted by the tokenizer).

Note

If the document.write()[p1099] method was called from script executing inline (i.e. executing because the parser parsed a set of script[p638] tags), then this is a reentrant invocation of the parser[p1211]. If the parser pause flag[p1212] is set, the tokenizer will abort immediately and no HTML will be parsed, per the tokenizer's parser pause flag check[p1229].

The **document.write(...)** method steps are to run the document write steps[p1099] with this and a string that is the concatenation of all arguments passed.

8.4.4 document.writeln()[p1099] §[p1099]

For web developers (non-normative)

***document*.writeln[p1099](...*text*)**

Adds the given string(s) to the Document[p127]'s input stream, followed by a newline character. If necessary, calls the open()[p1098] method implicitly first.

Throws an "InvalidStateError" DOMException when invoked on XML documents.

Throws an "InvalidStateError" DOMException if the parser is currently executing a custom element constructor[p742].

The **document.writeln(...)** method steps are to run the document write steps[p1099] with this and a string that is the concatenation of all arguments passed and U+000A LINE FEED.

8.5 DOM parsing §p1100

The DOMParser[p1100] interface allows authors to create new Document[p127] objects by parsing strings, as either HTML or XML.

For web developers (non-normative)

***parser* = new DOMParser[p1100]()**

Constructs a new DOMParser[p1100] object.

***document* = *parser*.parseFromString[p1100](*string*, *type*)**

Parses *string* using either the HTML or XML parser, according to *type*, and returns the resulting Document[p127]. *type* can be "text/html[p1380]" (which will invoke the HTML parser), or any of "text/xml[p1409]", "application/xml[p1408]", "application/xhtml+xml[p1382]", or "image/svg+xml[p1409]" (which will invoke the XML parser).

For the XML parser, if *string* cannot be parsed, then the returned Document[p127] will contain elements describing the resulting error.

Note that script[p638] elements are not evaluated during parsing, and the resulting document's encoding will always be UTF-8.

Values other than the above for *type* will cause a TypeError exception to be thrown.

Note

The design of DOMParser[p1100], as a class that needs to be constructed and then have its parseFromString()[p1100] method called, is an unfortunate historical artifact. If we were designing this functionality today it would be a standalone function.

IDL

```
[Exposed=Window]
interface DOMParser {
  constructor();

  [NewObject] Document parseFromString(DOMString string, DOMParserSupportedType type);
};

enum DOMParserSupportedType {
  "text/html",
  "text/xml",
  "application/xml",
  "application/xhtml+xml",
  "image/svg+xml"
};
```

The **new DOMParser()** constructor steps are to do nothing.

The **parseFromString(*string*, *type*)** method steps are:

1. Let *document* be a new Document[p127], whose content type is *type* and url is this's relevant global object[p1039]'s associated Document[p894]'s URL.

   Note

   The document's encoding will be left as its default, of UTF-8. In particular, any XML declarations or meta[p184] elements found while parsing string *will have no effect.*

2. Switch on *type*:

   ↪ **"text/html"**

   1. Set *document*'s type to "html".
   2. Create an HTML parser[p1210] *parser*, associated with *document*.
   3. Place *string* into the input stream[p1223] for *parser*. The encoding confidence[p1217] is *irrelevant*.
   4. Start *parser* and let it run until it has consumed all the characters just inserted into the input stream.

      Note

      This might mutate the document's mode.

Note

Since document *does not have a browsing context*[p961], *scripting is disabled*[p1039].

↪ ***Otherwise***

1. Create an XML parser[p1321] *parse*, associated with *document*, and with XML scripting support disabled[p1322].
2. Parse *string* using *parser*.
3. If the previous step resulted in an XML well-formedness or XML namespace well-formedness error, then:
    1. Assert: *document* has no child nodes.
    2. Let *root* be the result of creating an element given *document*, "`parsererror`", and "`http://www.mozilla.org/newlayout/xml/parsererror.xml`".
    3. Optionally, add attributes or children to *root* to describe the nature of the parsing error.
    4. Append *root* to *document*.

3. Return *document*.

8.6 Timers §[p1101]

The `setTimeout()`[p1102] and `setInterval()`[p1102] methods allow authors to schedule timer-based callbacks.

For web developers (non-normative)

***id* = self.setTimeout**[p1102]**(*handler* [, *timeout* [, ...*arguments*]])**

Schedules a timeout to run *handler* after *timeout* milliseconds. Any *arguments* are passed straight through to the *handler*.

***id* = self.setTimeout**[p1102]**(*code* [, *timeout*])**

Schedules a timeout to compile and run *code* after *timeout* milliseconds.

self.clearTimeout[p1102]**(*id*)**

Cancels the timeout set with `setTimeout()`[p1102] or `setInterval()`[p1102] identified by *id*.

***id* = self.setInterval**[p1102]**(*handler* [, *timeout* [, ...*arguments*]])**

Schedules a timeout to run *handler* every *timeout* milliseconds. Any *arguments* are passed straight through to the *handler*.

***id* = self.setInterval**[p1102]**(*code* [, *timeout*])**

Schedules a timeout to compile and run *code* every *timeout* milliseconds.

self.clearInterval[p1102]**(*id*)**

Cancels the timeout set with `setInterval()`[p1102] or `setTimeout()`[p1102] identified by *id*.

Note

Timers can be nested; after five such nested timers, however, the interval is forced to be at least four milliseconds.

Note

This API does not guarantee that timers will run exactly on schedule. Delays due to CPU load, other tasks, etc, are to be expected.

Objects that implement the `WindowOrWorkerGlobalScope`[p1094] mixin have a **map of active timers**, which is a map[p461], initially empty. Each key in this map is an identifier for a timer, and each value is a `DOMHighResTimeStamp`, representing the expiry time for that timer.

Note

For entries put in the map of active timers[p1101] *by the timer initialization steps*[p1102]*, i.e., by* `setTimeout()`[p1102] *and* `setInterval()`[p1102]*, the keys are numbers. For other specifications that use the run steps after a timeout*[p1104] *algorithm, the identifier is a unique non-numeric value. Only the numeric-keyed timers are affected by* `clearTimeout()`[p1102] *and* `clearInterval()`[p1102]*, but all timers contribute to idle deadline computation*[p1076]*, and are cleared when the relevant global is destroyed.*

The **`setTimeout(handler, timeout, ...arguments)`** method steps are to return the result of running the timer initialization steps[p1102] given this, *handler*, *timeout*, *arguments*, and false.

The **`setInterval(handler, timeout, ...arguments)`** method steps are to return the result of running the timer initialization steps[p1102] given this, *handler*, *timeout*, *arguments*, and true.

The **`clearTimeout(id)`** and **`clearInterval(id)`** method steps are to remove this's map of active timers[p1101][*id*].

Note

Because `clearTimeout()`[p1102] and `clearInterval()`[p1102] clear entries from the same map, either method can be used to clear timers created by `setTimeout()`[p1102] or `setInterval()`[p1102].

The **timer initialization steps**, given a `WindowOrWorkerGlobalScope`[p1094] *global*, a string or `Function` *handler*, a number *timeout*, a list *arguments*, a boolean *repeat*, and optionally (and only if *repeat* is true) a number *previousId*, are:

1. Let *thisArg* be *global* if that is a `WorkerGlobalScope`[p1166] object; otherwise let *thisArg* be the `WindowProxy`[p904] that corresponds to *global*.
2. If *previousId* was given, let *id* be *previousId*; otherwise, let *id* be an implementation-defined integer that is greater than zero and does not already exist in *global*'s map of active timers[p1101].
3. If the surrounding agent's event loop[p1071]'s currently running task[p1072] is a task that was created by this algorithm, then let *nesting level* be the task[p1071]'s timer nesting level[p1103]. Otherwise, let *nesting level* be zero.

   Note

   The task's timer nesting level[p1103] is used both for nested calls to `setTimeout()`[p1102], and for the repeating timers created by `setInterval()`[p1102]. (Or, indeed, for any combination of the two.) In other words, it represents nested invocations of this algorithm, not of a particular method.

4. If *timeout* is less than 0, then set *timeout* to 0.
5. If *nesting level* is greater than 5, and *timeout* is less than 4, then set *timeout* to 4.
6. Let *realm* be *global*'s relevant realm[p1039].
7. Let *initiating script* be the active script[p1041].
8. Assert: *initiating script* is not null, since this algorithm is always called from some script.
9. Let *task* be a task[p1071] that runs the following substeps:
   1. If *id* does not exist in *global*'s map of active timers[p1101], then abort these steps.
   2. If *handler* is a `Function`, then invoke *handler* given *arguments* with the callback this value set to *thisArg*. If this throws an exception, catch it, and report the exception[p1053].
   3. Otherwise:
      1. Assert: *handler* is a string.
      2. Perform HostEnsureCanCompileStrings[p1063](*realm*). If this throws an exception, catch it, report the exception[p1053], and abort these steps.
      3. Let *settings object* be *global*'s relevant settings object[p1039].
      4. Let *base URL* be *initiating script*'s base URL[p1040].
      5. Assert: *base URL* is not null, as *initiating script* is a classic script[p1040] or a JavaScript module script[p1040].
      6. Let *fetch options* be a script fetch options[p1041] whose cryptographic nonce[p1041] is *initiating script*'s fetch options[p1040]'s cryptographic nonce[p1041], integrity metadata[p1041] is the empty string, parser metadata[p1041] is "`not-parser-inserted`", credentials mode[p1041] is *initiating script*'s fetch options[p1040]'s credentials mode[p1041], referrer policy[p1041] is *initiating script*'s fetch options[p1040]'s referrer policy[p1041], and fetch priority[p1041] is "`auto`".

Note

The effect of these options ensures that the string compilation done by `setTimeout()`[p1102] *and* `setInterval()`[p1102] *behaves equivalently to that done by* `eval()`*. That is, module script*[p1040] *fetches via* `import()` *will behave the same in both contexts.*

7. Let *script* be the result of creating a classic script[p1048] given *handler*, *settings object*, *base URL*, and *fetch options*.

8. Run the classic script[p1050] *script*.

4. If *id* does not exist in *global*'s map of active timers[p1101], then abort these steps.

Note

It might have been removed via the author code in handler *calling* `clearTimeout()`[p1102] *or* `clearInterval()`[p1102].

5. If *repeat* is true, then perform the timer initialization steps[p1102] again, given *global*, *handler*, *timeout*, *arguments*, true, and *id*.

6. Otherwise, remove *global*'s map of active timers[p1101][*id*].

10. Increment *nesting level* by one.

11. Set *task*'s **timer nesting level** to *nesting level*.

12. Let *completionStep* be an algorithm step which queues a global task[p1073] on the **timer task source** given *global* to run *task*.

13. Run steps after a timeout[p1104] given *global*, "`setTimeout/setInterval`", *timeout*, *completionStep*, and *id*.

14. Return *id*.

Note

Argument conversion as defined by Web IDL (for example, invoking `toString()` *methods on objects passed as the first argument) happens in the algorithms defined in Web IDL, before this algorithm is invoked.*

Example

So for example, the following rather silly code will result in the log containing "`ONE TWO` ":

```
var log = '';
function logger(s) { log += s + ' '; }

setTimeout({ toString: function () {
  setTimeout("logger('ONE')", 100);
  return "logger('TWO')";
} }, 100);
```

Example

To run tasks of several milliseconds back to back without any delay, while still yielding back to the browser to avoid starving the user interface (and to avoid the browser killing the script for hogging the CPU), simply queue the next timer before performing work:

```
function doExpensiveWork() {
  var done = false;
  // ...
  // this part of the function takes up to five milliseconds
  // set done to true if we're done
  // ...
  return done;
}

function rescheduleWork() {
  var id = setTimeout(rescheduleWork, 0); // preschedule next iteration
```

```
  if (doExpensiveWork())
    clearTimeout(id); // clear the timeout if we don't need it
}

function scheduleWork() {
  setTimeout(rescheduleWork, 0);
}

scheduleWork(); // queues a task to do lots of work
```

To **run steps after a timeout**, given a `WindowOrWorkerGlobalScope`[p1094] *global*, a string *orderingIdentifier*, a number *milliseconds*, a set of steps *completionSteps*, and an optional value *timerKey*:

1. Assert: if *timerKey* is given, then the caller of this algorithm is the timer initialization steps[p1102]. (Other specifications must not pass *timerKey*.)
2. If *timerKey* is not given, then set it to a new unique non-numeric value.
3. Let *startTime* be the current high resolution time given *global*.
4. Set *global*'s map of active timers[p1101][*timerKey*] to *startTime* plus *milliseconds*.
5. Run the following steps in parallel[p43]:
    1. If *global* is a `Window`[p892] object, wait until *global*'s associated `Document`[p894] has been fully active[p966] for a further *milliseconds* milliseconds (not necessarily consecutively).

       Otherwise, *global* is a `WorkerGlobalScope`[p1166] object; wait until *milliseconds* milliseconds have passed with the worker not suspended (not necessarily consecutively).
    2. Wait until any invocations of this algorithm that had the same *global* and *orderingIdentifier*, that started before this one, and whose *milliseconds* is equal to or less than this one's, have completed.
    3. Optionally, wait a further implementation-defined length of time.

       Note

       This is intended to allow user agents to pad timeouts as needed to optimize the power usage of the device. For example, some processors have a low-power mode where the granularity of timers is reduced; on such platforms, user agents can slow timers down to fit this schedule instead of requiring the processor to use the more accurate mode with its associated higher power usage.
    4. Perform *completionSteps*.
    5. If *timerKey* is a non-numeric value, remove *global*'s map of active timers[p1101][*timerKey*].

Note

Run steps after a timeout[p1104] *is meant to be used by other specifications that want to execute developer-supplied code after a developer-supplied timeout, in a similar manner to* `setTimeout()`[p1102]*. (Note, however, it does not have the nesting and clamping behavior of* `setTimeout()`[p1102]*.) Such specifications can choose an* orderingIdentifier *to ensure ordering within their specification's timeouts, while not constraining ordering with respect to other specification's timeouts.*

8.7 Microtask queuing §[p1104]

MDN

For web developers (non-normative)

***self*.queueMicrotask**[p1104]**(*callback*)**

Queues[p1073] a microtask[p1072] to run the given *callback*.

The **`queueMicrotask(callback)`** method must queue a microtask[p1073] to invoke *callback*, and if *callback* throws an exception, report

the exception[p1053].

The queueMicrotask()[p1104] method allows authors to schedule a callback on the microtask queue[p1072]. This allows their code to run once the JavaScript execution context stack is next empty, which happens once all currently executing synchronous JavaScript has run to completion. This doesn't yield control back to the event loop[p1071], as would be the case when using, for example, setTimeout(*f*, 0)[p1102].

Authors ought to be aware that scheduling a lot of microtasks has the same performance downsides as running a lot of synchronous code. Both will prevent the browser from doing its own work, such as rendering. In many cases, requestAnimationFrame()[p1126] or requestIdleCallback() is a better choice. In particular, if the goal is to run code before the next rendering cycle, that is the purpose of requestAnimationFrame()[p1126].

As can be seen from the following examples, the best way of thinking about queueMicrotask()[p1104] is as a mechanism for rearranging synchronous code, effectively placing the queued code immediately after the currently executing synchronous JavaScript has run to completion.

Example

The most common reason for using queueMicrotask()[p1104] is to create consistent ordering, even in the cases where information is available synchronously, without introducing undue delay.

For example, consider a custom element firing a `load` event, that also maintains an internal cache of previously-loaded data. A naïve implementation might look like:

```
MyElement.prototype.loadData = function (url) {
  if (this._cache[url]) {
    this._setData(this._cache[url]);
    this.dispatchEvent(new Event("load"));
  } else {
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
  }
};
```

This naïve implementation is problematic, however, in that it causes its users to experience inconsistent behavior. For example, code such as

```
element.addEventListener("load", () => console.log("loaded"));
console.log("1");
element.loadData();
console.log("2");
```

will sometimes log "1, 2, loaded" (if the data needs to be fetched), and sometimes log "1, loaded, 2" (if the data is already cached). Similarly, after the call to `loadData()`, it will be inconsistent whether or not the data is set on the element.

To get a consistent ordering, queueMicrotask()[p1104] can be used:

```
MyElement.prototype.loadData = function (url) {
  if (this._cache[url]) {
    queueMicrotask(() => {
      this._setData(this._cache[url]);
      this.dispatchEvent(new Event("load"));
    });
  } else {
    fetch(url).then(res => res.arrayBuffer()).then(data => {
      this._cache[url] = data;
      this._setData(data);
      this.dispatchEvent(new Event("load"));
    });
```

```
  }
};
```

By essentially rearranging the queued code to be after the JavaScript execution context stack empties, this ensures a consistent ordering and update of the element's state.

Example

Another interesting use of queueMicrotask() p1104 is to allow uncoordinated "batching" of work by multiple callers. For example, consider a library function that wants to send data somewhere as soon as possible, but doesn't want to make multiple network requests if doing so is easily avoidable. One way to balance this would be like so:

```
const queuedToSend = [];

function sendData(data) {
  queuedToSend.push(data);

  if (queuedToSend.length === 1) {
    queueMicrotask(() => {
      const stringToSend = JSON.stringify(queuedToSend);
      queuedToSend.length = 0;

      fetch("/endpoint", stringToSend);
    });
  }
}
```

With this architecture, multiple subsequent calls to `sendData()` within the currently executing synchronous JavaScript will be batched together into one fetch() call, but with no intervening event loop tasks preempting the fetch (as would have happened with similar code that instead used setTimeout() p1102).

8.8 User prompts §p1106

8.8.1 Simple dialogs §p1106

For web developers (non-normative)

***window*.alert p1106(*message*)**

Displays a modal alert with the given message, and waits for the user to dismiss it.

***result* = *window*.confirm p1107(*message*)**

Displays a modal OK/Cancel prompt with the given message, waits for the user to dismiss it, and returns true if the user clicks OK and false if the user clicks Cancel.

***result* = *window*.prompt p1107(*message* [, *default*])**

Displays a modal text control prompt with the given message, waits for the user to dismiss it, and returns the value that the user entered. If the user cancels the prompt, then returns null instead. If the second argument is present, then the given value is used as a default.

Note

Logic that depends on tasks p1071 or microtasks p1072, such as media elements p406 loading their media data p407, are stalled when these methods are invoked.

The **alert()** and **alert(*message*)** method steps are:

1. If we cannot show simple dialogs p1108 for this, then return.
2. If the method was invoked with no arguments, then let *message* be the empty string; otherwise, let *message* be the

method's first argument.

3. Set *message* to the result of normalizing newlines given *message*.
4. Set *message* to the result of optionally truncating[p1107] *message*.
5. Show *message* to the user, treating U+000A LF as a line break.
6. Invoke WebDriver BiDi user prompt opened with this, "`alert`", and *message*.
7. Optionally, pause[p1080] while waiting for the user to acknowledge the message.
8. Invoke WebDriver BiDi user prompt closed with this and true.

Note

This method is defined using two overloads, instead of using an optional argument, for historical reasons. The practical impact of this is that `alert(undefined)` *is treated as* `alert("undefined")`*, but* `alert()` *is treated as* `alert("")`*.*

The **`confirm(`*`message`*`)`** method steps are:

1. If we cannot show simple dialogs[p1108] for this, then return false.
2. Set *message* to the result of normalizing newlines given *message*.
3. Set *message* to the result of optionally truncating[p1107] *message*.
4. Show *message* to the user, treating U+000A LF as a line break, and ask the user to respond with a positive or negative response.
5. Invoke WebDriver BiDi user prompt opened with this, "`confirm`", and *message*.
6. Pause[p1080] until the user responds either positively or negatively.
7. Invoke WebDriver BiDi user prompt closed with this, and true if the user responded positively or false otherwise.
8. If the user responded positively, return true; otherwise, the user responded negatively: return false.

The **`prompt(`*`message, default`*`)`** method steps are:

1. If we cannot show simple dialogs[p1108] for this, then return null.
2. Set *message* to the result of normalizing newlines given *message*.
3. Set *message* to the result of optionally truncating[p1107] *message*.
4. Set *default* to the result of optionally truncating[p1107] *default*.
5. Show *message* to the user, treating U+000A LF as a line break, and ask the user to either respond with a string value or abort. The response must be defaulted to the value given by *default*.
6. Invoke WebDriver BiDi user prompt opened with this, "`prompt`" and *message*.
7. Pause[p1080] while waiting for the user's response.
8. Let *result* be null if the user aborts, or otherwise the string that the user responded with.
9. Invoke WebDriver BiDi user prompt closed with this, false if *result* is null or true otherwise, and *result*.
10. Return *result*.

To **optionally truncate a simple dialog string** *s*, return either *s* itself or some string derived from *s* that is shorter. User agents should not provide UI for displaying the elided portion of *s*, as this makes it too easy for abusers to create dialogs of the form "Important security alert! Click 'Show More' for full details!".

Note

For example, a user agent might want to only display the first 100 characters of a message. Or, a user agent might replace the middle of the string with "...". These types of modifications can be useful in limiting the abuse potential of unnaturally large, trustworthy-looking system dialogs.

We **cannot show simple dialogs** for a Window[p892] *window* when the following algorithm returns true:

1. If the active sandboxing flag set[p887] of *window*'s associated Document[p894] has the sandboxed modals flag[p886] set, then return true.
2. If *window*'s relevant settings object[p1039]'s origin[p1032] and *window*'s relevant settings object[p1039]'s top-level origin[p1031] are not same origin-domain[p870], then return true.
3. If *window*'s relevant agent[p1029]'s event loop[p1071]'s termination nesting level[p1021] is nonzero, then optionally return true.
4. Optionally, return true. (For example, the user agent might give the user the option to ignore all modal dialogs, and would thus abort at this step whenever the method was invoked.)
5. Return false.

8.8.2 Printing §[p1108]

✔ MDN

For web developers (non-normative)

***window*.print[p1108]()**

Prompts the user to print the page.

The **print()** method steps are:

1. Let *document* be this's associated Document[p894].
2. If *document* is not fully active[p966], then return.
3. If *document*'s unload counter[p1021] is greater than 0, then return.
4. If *document* is ready for post-load tasks[p1297], then run the printing steps[p1108] for *document*.
5. Otherwise, set *document*'s **print when loaded** flag.

User agents should also run the printing steps[p1108] whenever the user asks for the opportunity to obtain a physical form[p1359] (e.g. printed copy), or the representation of a physical form (e.g. PDF copy), of a document.

The **printing steps** for a Document[p127] *document* are:

1. The user agent may display a message to the user or return (or both).

   Example

   For instance, a kiosk browser could silently ignore any invocations of the print()[p1108] method.

   Example

   For instance, a browser on a mobile device could detect that there are no printers in the vicinity and display a message saying so before continuing to offer a "save to PDF" option.

2. If the active sandboxing flag set[p887] of *document* has the sandboxed modals flag[p886] set, then return.

   Note

   If the printing dialog is blocked by a Document[p127]'s sandbox, then neither the beforeprint[p1406] nor afterprint[p1406] events will be fired.

3. The user agent must fire an event named beforeprint[p1406] at the relevant global object[p1039] of *document*, as well as any child navigable[p955] in it.

   Firing in children only doesn't seem right here, and some tasks likely need to be queued. See issue #5096.

   Example

   The beforeprint[p1406] event can be used to annotate the printed copy, for instance adding the time at which the document was printed.

4. The user agent should offer the user the opportunity to obtain a physical form[p1359] (or the representation of a physical form) of *document*. The user agent may wait for the user to either accept or decline before returning; if so, the user agent must pause[p1080] while the method is waiting. Even if the user agent doesn't wait at this point, the user agent must use the state of the relevant documents as they are at this point in the algorithm if and when it eventually creates the alternate form.

5. The user agent must fire an event named `afterprint`[p1406] at the relevant global object[p1039] of *document*, as well as any child navigables[p955] in it.

Firing in children only doesn't seem right here, and some tasks likely need to be queued. See issue #5096.

Example

The `afterprint`[p1406] event can be used to revert annotations added in the earlier event, as well as showing post-printing UI. For instance, if a page is walking the user through the steps of applying for a home loan, the script could automatically advance to the next step after having printed a form or other.

8.9 System state and capabilities §[p1109]

8.9.1 The `Navigator`[p1109] object §[p1109]

Instances of `Navigator`[p1109] represent the identity and state of the user agent (the client). They also serve as a generic global under which various APIs are located in this and other specifications.

IDL
```
[Exposed=Window]
interface Navigator {
  // objects implementing this interface also implement the interfaces given below
};
Navigator includes NavigatorID;
Navigator includes NavigatorLanguage;
Navigator includes NavigatorOnLine;
Navigator includes NavigatorContentUtils;
Navigator includes NavigatorCookies;
Navigator includes NavigatorPlugins;
Navigator includes NavigatorConcurrentHardware;
```

Note

These interface mixins are defined separately so that `WorkerNavigator`[p1179] can reuse parts of the `Navigator`[p1109] interface.

Each `Window`[p892] has an **associated `Navigator`**, which is a `Navigator`[p1109] object. Upon creation of the `Window`[p892] object, its associated `Navigator`[p1109] must be set to a new `Navigator`[p1109] object created in the `Window`[p892] object's relevant realm[p1039].

The **`navigator`** and **`clientInformation`** getter steps are to return this's associated `Navigator`[p1109].

8.9.1.1 Client identification §[p1109]

IDL
```
interface mixin NavigatorID {
  readonly attribute DOMString appCodeName; // constant "Mozilla"
  readonly attribute DOMString appName; // constant "Netscape"
  readonly attribute DOMString appVersion;
  readonly attribute DOMString platform;
  readonly attribute DOMString product; // constant "Gecko"
  [Exposed=Window] readonly attribute DOMString productSub;
  readonly attribute DOMString userAgent;
  [Exposed=Window] readonly attribute DOMString vendor;
  [Exposed=Window] readonly attribute DOMString vendorSub; // constant ""
};
```

In certain cases, despite the best efforts of the entire industry, web browsers have bugs and limitations that web authors are forced to work around.

This section defines a collection of attributes that can be used to determine, from script, the kind of user agent in use, in order to work around these issues.

The user agent has a **navigator compatibility mode**, which is either *Chrome*, *Gecko*, or *WebKit*.

Note

The navigator compatibility mode[p1110] constrains the `NavigatorID`[p1109] mixin to the combinations of attribute values and presence of `taintEnabled()`[p1111] and `oscpu`[p1111] that are known to be compatible with existing web content.

Client detection should always be limited to detecting known current versions; future versions and unknown versions should always be assumed to be fully compliant.

For web developers (non-normative)

***self*.navigator[p1109].appCodeName[p1110]**
Returns the string "Mozilla".

***self*.navigator[p1109].appName[p1110]**
Returns the string "Netscape".

***self*.navigator[p1109].appVersion[p1110]**
Returns the version of the browser.

***self*.navigator[p1109].platform[p1111]**
Returns the name of the platform.

***self*.navigator[p1109].product[p1111]**
Returns the string "Gecko".

***window*.navigator[p1109].productSub[p1111]**
Returns either the string "20030107", or the string "20100101".

***self*.navigator[p1109].userAgent[p1111]**
Returns the complete `User-Agent` header.

***window*.navigator[p1109].vendor[p1111]**
Returns either the empty string, the string "Apple Computer, Inc.", or the string "Google Inc.".

***window*.navigator[p1109].vendorSub[p1111]**
Returns the empty string.

appCodeName
Must return the string "Mozilla".

appName
Must return the string "Netscape".

appVersion
Must return the appropriate string that starts with "5.0 (", as follows:

Let *trail* be the substring of default `User-Agent` value that follows the "Mozilla/" prefix.

↪ **If the navigator compatibility mode[p1110] is *Chrome* or *WebKit***
Return *trail*.

↪ **If the navigator compatibility mode[p1110] is *Gecko***
If *trail* starts with "5.0 (Windows", then return "5.0 (Windows)".

Otherwise, return the prefix of *trail* up to but not including the first U+003B (;), concatenated with the character U+0029 RIGHT PARENTHESIS. For example, "5.0 (Macintosh)", "5.0 (Android 10)", or "5.0 (X11)".

platform

Must return a string representing the platform on which the browser is executing (e.g. "`MacIntel`", "`Win32`", "`Linux x86_64`", "`Linux armv81`") or, for privacy and compatibility, a string that is commonly returned on another platform.

product

Must return the string "`Gecko`".

productSub

Must return the appropriate string from the following list:

↪ **If the navigator compatibility mode[p1110] is *Chrome* or *WebKit***
The string "`20030107`".

↪ **If the navigator compatibility mode[p1110] is *Gecko***
The string "`20100101`".

userAgent

Must return the default `User-Agent` value.

vendor

Must return the appropriate string from the following list:

↪ **If the navigator compatibility mode[p1110] is *Chrome***
The string "`Google Inc.`".

↪ **If the navigator compatibility mode[p1110] is *Gecko***
The empty string.

↪ **If the navigator compatibility mode[p1110] is *WebKit***
The string "`Apple Computer, Inc.`".

vendorSub

Must return the empty string.

If the navigator compatibility mode[p1110] is *Gecko*, then the user agent must also support the following partial interface:

```
IDL
partial interface mixin NavigatorID {
  [Exposed=Window] boolean taintEnabled(); // constant false
  [Exposed=Window] readonly attribute DOMString oscpu;
};
```

The **`taintEnabled()`** method must return false.

The **`oscpu`** attribute's getter must return either the empty string or a string representing the platform on which the browser is executing, e.g. "`Windows NT 10.0; Win64; x64`", "`Linux x86_64`".

⚠Warning!

Any information in this API that varies from user to user can be used to profile the user. In fact, if enough such information is available, a user can actually be uniquely identified. For this reason, user agent implementers are strongly urged to include as little information in this API as possible.

8.9.1.2 Language preferences §[p11]

```
IDL
interface mixin NavigatorLanguage {
  readonly attribute DOMString language;
  readonly attribute FrozenArray<DOMString> languages;
};
```

For web developers (non-normative)

***self*.navigator[p1109].language[p1112]**

Returns a language tag representing the user's preferred language.

***self*.navigator[p1109].languages[p1112]**

Returns an array of language tags representing the user's preferred languages, with the most preferred language first.

The most preferred language is the one returned by navigator.language[p1112].

Note

A languagechange[p1407] event is fired at the Window[p892] or WorkerGlobalScope[p1166] object when the user agent's understanding of what the user's preferred languages are changes.

language

Must return a valid BCP 47 language tag representing either a plausible language[p1112] or the user's most preferred language. [BCP47][p1410]

languages

Must return a frozen array of valid BCP 47 language tags representing either one or more plausible languages[p1112], or the user's preferred languages, ordered by preference with the most preferred language first. The same object must be returned until the user agent needs to return different values, or values in a different order. [BCP47][p1410]

Whenever the user agent needs to make the navigator.languages[p1112] attribute of a Window[p892] or WorkerGlobalScope[p1166] object *global* return a new set of language tags, the user agent must queue a global task[p1073] on the DOM manipulation task source[p1080] given *global* to fire an event named languagechange[p1407] at *global*, and wait until that task begins to be executed before actually returning a new value.

To determine **a plausible language**, the user agent should bear in mind the following:

- Any information in this API that varies from user to user can be used to profile or identify the user.
- If the user is not using a service that obfuscates the user's point of origin (e.g. the Tor anonymity network), then the value that is least likely to distinguish the user from other users with similar origins (e.g. from the same IP address block) is the language used by the majority of such users. [TOR][p1417]
- If the user is using an anonymizing service, then the value "en-US" is suggested; if all users of the service use that same value, that reduces the possibility of distinguishing the users from each other.

To avoid introducing any more fingerprinting vectors, user agents should use the same list for the APIs defined in this function as for the HTTP `Accept-Language` header.

8.9.1.3 Browser state §[p1112]

```
IDL
interface mixin NavigatorOnLine {
  readonly attribute boolean onLine;
};
```

For web developers (non-normative)

***self*.navigator[p1109].onLine[p1112]**

Returns false if the user agent is definitely offline (disconnected from the network). Returns true if the user agent might be online.

The events online[p1407] and offline[p1407] are fired when the value of this attribute changes.

The **onLine** attribute must return false if the user agent will not contact the network when the user follows links or when a script requests a remote page (or knows that such an attempt would fail), and must return true otherwise.

When the value that would be returned by the navigator.onLine[p1112] attribute of a Window[p892] or WorkerGlobalScope[p1166] *global* changes from true to false, the user agent must queue a global task[p1073] on the networking task source[p1081] given *global* to fire an event named offline[p1407] at *global*.

On the other hand, when the value that would be returned by the navigator.onLine[p1112] attribute of a Window[p892] or WorkerGlobalScope[p1166] *global* changes from false to true, the user agent must queue a global task[p1073] on the networking task source[p1081] given *global* to fire an event named online[p1407] at the Window[p892] or WorkerGlobalScope[p1166] object.

Note

This attribute is inherently unreliable. A computer can be connected to a network without having Internet access.

Example

In this example, an indicator is updated as the browser goes online and offline.

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <title>Online status</title>
  <script>
   function updateIndicator() {
     document.getElementById('indicator').textContent = navigator.onLine ? 'online' : 'offline';
   }
  </script>
 </head>
 <body onload="updateIndicator()" ononline="updateIndicator()" onoffline="updateIndicator()">
  <p>The network is: <span id="indicator">(state unknown)</span>
 </body>
</html>
```

MDN

8.9.1.4 Custom scheme handlers: the registerProtocolHandler()[p1113] method §[p1113]

IDL

```
interface mixin NavigatorContentUtils {
  [SecureContext] undefined registerProtocolHandler(DOMString scheme, USVString url);
  [SecureContext] undefined unregisterProtocolHandler(DOMString scheme, USVString url);
};
```

For web developers (non-normative)

***window*.navigator[p1109].registerProtocolHandler[p1113](*scheme, url*)**

Registers a handler for *scheme* at *url*. For example, an online telephone messaging service could register itself as a handler of the sms: scheme, so that if the user clicks on such a link, they are given the opportunity to use that web site. [SMS][p1417]

The string "%s" in *url* is used as a placeholder for where to put the URL of the content to be handled.

Throws a "SecurityError" DOMException if the user agent blocks the registration (this might happen if trying to register as a handler for "http", for instance).

Throws a "SyntaxError" DOMException if the "%s" string is missing in *url*.

***window*.navigator[p1109].unregisterProtocolHandler[p1114](*scheme, url*)**

Unregisters the handler given by the arguments.

Throws a "SecurityError" DOMException if the user agent blocks the deregistration (this might happen if with invalid schemes, for instance).

Throws a "SyntaxError" DOMException if the "%s" string is missing in *url*.

The **registerProtocolHandler(*scheme, url*)** method steps are:

1. Let (*normalizedScheme*, *normalizedURLString*) be the result of running normalize protocol handler parameters[p1114] with *scheme*, *url*, and this's relevant settings object[p1039].

2. In parallel[p43]: **register a protocol handler** for *normalizedScheme* and *normalizedURLString*. User agents may, within the constraints described, do whatever they like. A user agent could, for instance, prompt the user and offer the user the opportunity to add the site to a shortlist of handlers, or make the handlers their default, or cancel the request. User agents could also silently collect the information, providing it only when relevant to the user.

User agents should keep track of which sites have registered handlers (even if the user has declined such registrations) so that the user is not repeatedly prompted with the same request.

If the `registerProtocolHandler()` automation mode[p1116] of this's relevant global object[p1039]'s associated `Document`[p894] is not "**none**", the user agent should first verify that it is in an automation context (see WebDriver's security considerations). The user agent should then bypass the above communication of information and gathering of user consent, and instead do the following based on the value of the `registerProtocolHandler()` automation mode[p1116]:

"**auto-accept**"
: Act as if the user has seen the registration details and accepted the request.

"**auto-reject**"
: Act as if the user has seen the registration details and rejected the request.

When the **user agent uses this handler** for a URL *inputURL*:

1. Assert: *inputURL*'s scheme is *normalizedScheme*.
2. Set the username given *inputURL* and the empty string.
3. Set the password given *inputURL* and the empty string.
4. Let *inputURLString* be the serialization of *inputURL*.
5. Let *encodedURL* be the result of running UTF-8 percent-encode on *inputURLString* using the component percent-encode set.
6. Let *handlerURLString* be *normalizedURLString*.
7. Replace the first instance of "`%s`" in *handlerURLString* with *encodedURL*.
8. Let *resultURL* be the result of parsing *handlerURLString*.
9. Navigate[p977] an appropriate navigable[p952] to *resultURL*.

Example

If the user had visited a site at `https://example.com/` that made the following call:

```
navigator.registerProtocolHandler('web+soup', 'soup?url=%s')
```

...and then, much later, while visiting `https://www.example.net/`, clicked on a link such as:

```
<a href="web+soup:chicken-kïwi">Download our Chicken Kïwi soup!</a>
```

...then the UA might navigate to the following URL:

`https://example.com/soup?url=web+soup:chicken-k%C3%AFwi`

This site could then do whatever it is that it does with soup (synthesize it and ship it to the user, or whatever).

This does not define when the handler is used. To some extent, the processing model for navigating across documents[p977] defines some cases where it is relevant, but in general user agents may use this information wherever they would otherwise consider handing schemes to native plugins or helper applications.

The **`unregisterProtocolHandler(`*`scheme, url`*`)`** method steps are:

1. Let (*normalizedScheme*, *normalizedURLString*) be the result of running normalize protocol handler parameters[p1114] with *scheme*, *url*, and this's relevant settings object[p1039].
2. In parallel[p43]: unregister the handler described by *normalizedScheme* and *normalizedURLString*.

To **normalize protocol handler parameters**, given a string *scheme*, a string *url*, and an environment settings object[p1032] *environment*, run these steps:

1. Set *scheme* to *scheme*, converted to ASCII lowercase.

2. If *scheme* is neither a safelisted scheme[p1115] nor a string starting with "`web+`" followed by one or more ASCII lower alphas, then throw a "`SecurityError`" `DOMException`.

   Note
   This means that including a colon in scheme *(as in* "`mailto:`"*) will throw.*

   The following schemes are the **safelisted schemes**:

   - `bitcoin`
   - `ftp`
   - `ftps`
   - `geo`
   - `im`
   - `irc`
   - `ircs`
   - `magnet`
   - `mailto`
   - `matrix`
   - `mms`
   - `news`
   - `nntp`
   - `openpgp4fpr`
   - `sftp`
   - `sip`
   - `sms`
   - `smsto`
   - `ssh`
   - `tel`
   - `urn`
   - `webcal`
   - `wtai`
   - `xmpp`

   Note
   This list can be changed. If there are schemes that ought to be added, please send feedback.

3. If *url* does not contain "`%s`", then throw a "`SyntaxError`" `DOMException`.

4. Parse[p95] *url* relative to *environment*.

5. If that fails, then throw a "`SyntaxError`" `DOMException`.

   Note
   This is forcibly the case if the `%s` *placeholder is in the host or port of the URL.*

6. If the resulting URL record[p95]'s scheme is not an HTTP(S) scheme or the resulting URL record[p95]'s origin is not same origin[p870] with *environment*'s origin[p1032], then throw a "`SecurityError`" `DOMException`.

7. Assert: the result of Is url potentially trustworthy? given the resulting URL record[p95] is "`Potentially Trustworthy`".

   Note
   Because normalize protocol handler parameters[p1114] is run within a secure context[p1039], this is implied by the same origin[p870] condition.

8. Return (*scheme*, resulting URL string[p95]).

   Note
   The resulting URL string[p95] will by definition not be a valid URL string as it includes the string "`%s`" *which is not a valid component in a URL.*

8.9.1.4.1 Security and privacy §[p1115]

Custom scheme handlers can introduce a number of concerns, in particular privacy concerns.

Hijacking all web usage. User agents should not allow schemes that are key to its normal operation, such as an HTTP(S) scheme, to be rerouted through third-party sites. This would allow a user's activities to be trivially tracked, and would allow user information, even in secure connections, to be collected.

Hijacking defaults. User agents are strongly urged to not automatically change any defaults, as this could lead the user to send data to remote hosts that the user is not expecting. New handlers registering themselves should never automatically cause those sites to be used.

Registration spamming. User agents should consider the possibility that a site will attempt to register a large number of handlers, possibly from multiple domains (e.g., by redirecting through a series of pages each on a different domain, and each registering a handler for `web+spam:` — analogous practices abusing other web browser features have been used by pornography web sites for many years). User agents should gracefully handle such hostile attempts, protecting the user.

Hostile handler metadata. User agents should protect against typical attacks against strings embedded in their interface, for example ensuring that markup or escape characters in such strings are not executed, that null bytes are properly handled, that over-long strings do not cause crashes or buffer overruns, and so forth.

Leaking private data. Web page authors may reference a custom scheme handler using URL data considered private. They might do so with the expectation that the user's choice of handler points to a page inside the organization, ensuring that sensitive data will not be exposed to third parties. However, a user may have registered a handler pointing to an external site, resulting in a data leak to that third party. Implementers might wish to consider allowing administrators to disable custom handlers on certain subdomains, content types, or schemes.

Interface interference. User agents should be prepared to handle intentionally long arguments to the methods. For example, if the user interface exposed consists of an "accept" button and a "deny" button, with the "accept" binding containing the name of the handler, it's important that a long name not cause the "deny" button to be pushed off the screen.

8.9.1.4.2 User agent automation §[p1116]

Each `Document`[p127] has a **`registerProtocolHandler()` automation mode**. It defaults to "`none`[p1114]", but it also can be either "`auto-accept`[p1114]" or "`auto-reject`[p1114]".

For the purposes of user agent automation and website testing, this standard defines **Set RPH Registration Mode** WebDriver extension command. It instructs the user agent to place a `Document`[p127] into a mode where it will automatically simulate a user either accepting or rejecting and registration confirmation prompt dialog.

HTTP Method	URI Template
`POST`	`/session/{session id}/custom-handlers/set-mode`

The remote end steps are:

1. If *parameters* is not a JSON Object, return a WebDriver error with WebDriver error code invalid argument.
2. Let *mode* be the result of getting a property named "`mode`" from *parameters*.
3. If *mode* is not "`auto-accept`[p1114]", "`auto-reject`[p1114], or "`none`[p1114]", return a WebDriver error with WebDriver error code invalid argument.
4. Let *document* be the current browsing context's active document[p961].
5. Set *document*'s `registerProtocolHandler()` automation mode[p1116] to *mode*.
6. Return success with data null.

8.9.1.5 Cookies §[p1116]

IDL
```
interface mixin NavigatorCookies {
  readonly attribute boolean cookieEnabled;
};
```

For web developers (non-normative)

***window*.navigator**[p1109]**.cookieEnabled**[p1117]

Returns false if setting a cookie will be ignored, and true otherwise.

The **cookieEnabled** attribute must return true if the user agent attempts to handle cookies according to *HTTP State Management Mechanism*, and false if it ignores cookie change requests. [COOKIES][p1411]

8.9.1.6 PDF viewing support §[p1117]

For web developers (non-normative)

***window*.navigator[p1109].pdfViewerEnabled[p1118]**

Returns true if the user agent supports inline viewing of PDF files when navigating[p977] to them, or false otherwise. In the latter case, PDF files will be handled by external software[p986].

IDL

```
interface mixin NavigatorPlugins {
  [SameObject] readonly attribute PluginArray plugins;
  [SameObject] readonly attribute MimeTypeArray mimeTypes;
  boolean javaEnabled();
  readonly attribute boolean pdfViewerEnabled;
};

[Exposed=Window,
 LegacyUnenumerableNamedProperties]
interface PluginArray {
  undefined refresh();
  readonly attribute unsigned long length;
  getter Plugin? item(unsigned long index);
  getter Plugin? namedItem(DOMString name);
};

[Exposed=Window,
 LegacyUnenumerableNamedProperties]
interface MimeTypeArray {
  readonly attribute unsigned long length;
  getter MimeType? item(unsigned long index);
  getter MimeType? namedItem(DOMString name);
};

[Exposed=Window,
 LegacyUnenumerableNamedProperties]
interface Plugin {
  readonly attribute DOMString name;
  readonly attribute DOMString description;
  readonly attribute DOMString filename;
  readonly attribute unsigned long length;
  getter MimeType? item(unsigned long index);
  getter MimeType? namedItem(DOMString name);
};

[Exposed=Window]
interface MimeType {
  readonly attribute DOMString type;
  readonly attribute DOMString description;
  readonly attribute DOMString suffixes;
  readonly attribute Plugin enabledPlugin;
};
```

Although these days detecting PDF viewer support can be done via navigator.pdfViewerEnabled[p1118], for historical reasons, there are a number of complex and intertwined interfaces that provide the same capability, which legacy code relies on. This section specifies both the simple modern variant and the complicated historical one.

Each user agent has a **PDF viewer supported** boolean, whose value is implementation-defined (and might vary according to user preferences).

Note

This value also impacts the navigation[p977] processing model.

Each Window[p892] object has a **PDF viewer plugin objects** list. If the user agent's PDF viewer supported[p1117] is false, then it is the empty list. Otherwise, it is a list containing five Plugin[p1117] objects, whose names[p1119] are, respectively:

0. "PDF Viewer"
1. "Chrome PDF Viewer"
2. "Chromium PDF Viewer"
3. "Microsoft Edge PDF Viewer"
4. "WebKit built-in PDF"

The values of the above list form the **PDF viewer plugin names** list.

Note

These names were chosen based on evidence of what websites historically search for, and thus what is necessary for user agents to expose in order to maintain compatibility with existing content. They are ordered alphabetically. The "PDF Viewer" name was then inserted in the 0th position so that the enabledPlugin[p1119] getter could point to a generic plugin name.

Each Window[p892] object has a **PDF viewer mime type objects** list. If the user agent's PDF viewer supported[p1117] is false, then it is the empty list. Otherwise, it is a list containing two MimeType[p1117] objects, whose types[p1119] are, respectively:

0. "application/pdf"
1. "text/pdf"

The values of the above list form the **PDF viewer mime types** list.

Each NavigatorPlugins[p1117] object has a **plugins array**, which is a new PluginArray[p1117], and a **mime types array**, which is a new MimeTypeArray[p1117].

The NavigatorPlugins[p1117] mixin's **plugins** getter steps are to return this's plugins array[p1118].

The NavigatorPlugins[p1117] mixin's **mimeTypes** getter steps are to return this's mime types array[p1118].

The NavigatorPlugins[p1117] mixin's **javaEnabled()** method steps are to return false.

The NavigatorPlugins[p1117] mixin's **pdfViewerEnabled** getter steps are to return the user agent's PDF viewer supported[p1117].

The PluginArray[p1117] interface supports named properties. If the user agent's PDF viewer supported[p1117] is true, then they are the PDF viewer plugin names[p1118]. Otherwise, they are the empty list.

The PluginArray[p1117] interface's **namedItem(*name*)** method steps are:

1. For each Plugin[p1117] *plugin* of this's relevant global object[p1039]'s PDF viewer plugin objects[p1118]: if *plugin*'s name[p1119] is *name*, then return *plugin*.
2. Return null.

The PluginArray[p1117] interface supports indexed properties. The supported property indices are the indices of this's relevant global object[p1039]'s PDF viewer plugin objects[p1118].

The PluginArray[p1117] interface's **item(*index*)** method steps are:

1. Let *plugins* be this's relevant global object[p1039]'s PDF viewer plugin objects[p1118].
2. If *index* < *plugins*'s size, then return *plugins*[*index*].
3. Return null.

The PluginArray[p1117] interface's **length** getter steps are to return this's relevant global object[p1039]'s PDF viewer plugin objects[p1118]'s size.

The PluginArray[p1117] interface's **refresh()** method steps are to do nothing.

The MimeTypeArray[p1117] interface supports named properties. If the user agent's PDF viewer supported[p1117] is true, then they are the PDF viewer mime types[p1118]. Otherwise, they are the empty list.

The MimeTypeArray[p1117] interface's **namedItem(*name*)** method steps are:

1. For each MimeType[p1117] *mimeType* of this's relevant global object[p1039]'s PDF viewer mime type objects[p1118]: if *mimeType*'s type[p1119] is *name*, then return *mimeType*.
2. Return null.

The MimeTypeArray[p1117] interface supports indexed properties. The supported property indices are the indices of this's relevant global object[p1039]'s PDF viewer mime type objects[p1118].

The MimeTypeArray[p1117] interface's **item(*index*)** method steps are:

1. Let *mimeTypes* be this's relevant global object[p1039]'s PDF viewer mime type objects[p1118].
2. If *index* < *mimeTypes*'s size, then return *mimeTypes*[*index*].
3. Return null.

The MimeTypeArray[p1117] interface's **length** getter steps are to return this's relevant global object[p1039]'s PDF viewer mime type objects[p1118]'s size.

Each Plugin[p1117] object has a **name**, which is set when the object is created.

The Plugin[p1117] interface's **name** getter steps are to return this's name[p1119].

The Plugin[p1117] interface's **description** getter steps are to return "`Portable Document Format`".

The Plugin[p1117] interface's **filename** getter steps are to return "`internal-pdf-viewer`".

The Plugin[p1117] interface supports named properties. If the user agent's PDF viewer supported[p1117] is true, then they are the PDF viewer mime types[p1118]. Otherwise, they are the empty list.

The Plugin[p1117] interface's **namedItem(*name*)** method steps are:

1. For each MimeType[p1117] *mimeType* of this's relevant global object[p1039]'s PDF viewer mime type objects[p1118]: if *mimeType*'s type[p1119] is *name*, then return *mimeType*.
2. Return null.

The Plugin[p1117] interface supports indexed properties. The supported property indices are the indices of this's relevant global object[p1039]'s PDF viewer mime type objects[p1118].

The Plugin[p1117] interface's **item(*index*)** method steps are:

1. Let *mimeTypes* be this's relevant global object[p1039]'s PDF viewer mime type objects[p1118].
2. If *index* < *mimeType*'s size, then return *mimeTypes*[*index*].
3. Return null.

The Plugin[p1117] interface's **length** getter steps are to return this's relevant global object[p1039]'s PDF viewer mime type objects[p1118]'s size.

Each MimeType[p1117] object has a **type**, which is set when the object is created.

The MimeType[p1117] interface's **type** getter steps are to return this's type[p1119].

The MimeType[p1117] interface's **description** getter steps are to return "`Portable Document Format`".

The MimeType[p1117] interface's **suffixes** getter steps are to return "`pdf`".

The MimeType[p1117] interface's **enabledPlugin** getter steps are to return this's relevant global object[p1039]'s PDF viewer plugin

objects[p1118][0] (i.e., the generic "PDF Viewer" one).

8.10 Images §[p1120]

IDL

```
[Exposed=(Window,Worker), Serializable, Transferable]
interface ImageBitmap {
  readonly attribute unsigned long width;
  readonly attribute unsigned long height;
  undefined close();
};

typedef (CanvasImageSource or
         Blob or
         ImageData) ImageBitmapSource;

enum ImageOrientation { "from-image", "flipY" };
enum PremultiplyAlpha { "none", "premultiply", "default" };
enum ColorSpaceConversion { "none", "default" };
enum ResizeQuality { "pixelated", "low", "medium", "high" };

dictionary ImageBitmapOptions {
  ImageOrientation imageOrientation = "from-image";
  PremultiplyAlpha premultiplyAlpha = "default";
  ColorSpaceConversion colorSpaceConversion = "default";
  [EnforceRange] unsigned long resizeWidth;
  [EnforceRange] unsigned long resizeHeight;
  ResizeQuality resizeQuality = "low";
};
```

An ImageBitmap[p1120] object represents a bitmap image that can be painted to a canvas without undue latency.

Note

The exact judgement of what is undue latency of this is left up to the implementer, but in general if making use of the bitmap requires network I/O, or even local disk I/O, then the latency is probably undue; whereas if it only requires a blocking read from a GPU or system RAM, the latency is probably acceptable.

For web developers (non-normative)

***promise* = self.createImageBitmap[p1121](*image* [, *options*])**

***promise* = self.createImageBitmap[p1121](*image*, *sx*, *sy*, *sw*, *sh* [, *options*])**

Takes *image*, which can be an img[p338] element, an SVG image element, a video[p398] element, a canvas[p661] element, a Blob object, an ImageData[p670] object, or another ImageBitmap[p1120] object, and returns a promise that is resolved when a new ImageBitmap[p1120] is created.

If no ImageBitmap[p1120] object can be constructed, for example because the provided *image* data is not actually an image, then the promise is rejected instead.

If *sx*, *sy*, *sw*, and *sh* arguments are provided, the source image is cropped to the given pixels, with any pixels missing in the original replaced by transparent black. These coordinates are in the source image's pixel coordinate space, *not* in CSS pixels.

If *options* is provided, the ImageBitmap[p1120] object's bitmap data is modified according to *options*. For example, if the premultiplyAlpha[p1124] option is set to "premultiply[p1124]", the bitmap data[p1121]'s color channels are premultiplied by its alpha channel[p732].

Rejects the promise with an "InvalidStateError" DOMException if the source image is not in a valid state (e.g., an img[p338] element that hasn't loaded successfully, an ImageBitmap[p1120] object whose [[Detached]][p116] internal slot value is true, an ImageData[p670] object whose data[p711] attribute value's [[ViewedArrayBuffer]] internal slot is detached, or a Blob whose data cannot be interpreted as a bitmap image).

Rejects the promise with a "SecurityError" DOMException if the script is not allowed to access the image data of the source image (e.g. a video[p398] that is CORS-cross-origin[p95], or a canvas[p661] being drawn on by a script in a worker from another

origin[p869]).

***imageBitmap*.close[p1124]()**

Releases *imageBitmap*'s underlying bitmap data[p1121].

***imageBitmap*.width[p1124]**

Returns the natural width of the image, in CSS pixels.

***imageBitmap*.height[p1124]**

Returns the natural height of the image, in CSS pixels.

An `ImageBitmap`[p1120] object whose [[Detached]][p116] internal slot value is false always has associated **bitmap data**, with a width and a height. However, it is possible for this data to be corrupted. If an `ImageBitmap`[p1120] object's media data can be decoded without errors, it is said to be **fully decodable**.

An `ImageBitmap`[p1120] object's bitmap has an origin-clean[p663] flag, which indicates whether the bitmap is tainted by content from a different origin[p869]. The flag is initially set to true and may be changed to false by the steps of `createImageBitmap()`[p1121].

`ImageBitmap`[p1120] objects are serializable objects[p114] and transferable objects[p115].

Their serialization steps[p114], given *value* and *serialized*, are:

1. If *value*'s origin-clean[p663] flag is not set, then throw a `"DataCloneError"` `DOMException`.
2. Set *serialized*.[[BitmapData]] to a copy of *value*'s bitmap data[p1121].

Their deserialization steps[p114], given *serialized*, *value*, and *targetRealm*, are:

1. Set *value*'s bitmap data[p1121] to *serialized*.[[BitmapData]].

Their transfer steps[p116], given *value* and *dataHolder*, are:

1. If *value*'s origin-clean[p663] flag is not set, then throw a `"DataCloneError"` `DOMException`.
2. Set *dataHolder*.[[BitmapData]] to *value*'s bitmap data[p1121].
3. Unset *value*'s bitmap data[p1121].

Their transfer-receiving steps[p116], given *dataHolder* and *value*, are:

1. Set *value*'s bitmap data[p1121] to *dataHolder*.[[BitmapData]].

The **`createImageBitmap(`*`image, options`*`)`** and `createImageBitmap(`*`image sx, sy, sw, sh, options`*`)` methods, when invoked, must run these steps:

1. If either *sw* or *sh* is given and is 0, then return a promise rejected with a `RangeError`.
2. If either *options*'s **`resizeWidth`** or *options*'s **`resizeHeight`** is present and is 0, then return a promise rejected with an `"InvalidStateError"` `DOMException`.
3. Check the usability of the *image* argument[p695]. If this throws an exception or returns *bad*, then return a promise rejected with an `"InvalidStateError"` `DOMException`.
4. Let *p* be a new promise.
5. Let *imageBitmap* be a new `ImageBitmap`[p1120] object.
6. Switch on *image*:

   ↪ **`img`**[p338]

   ↪ **SVG `image`**

   1. If *image*'s media data has no natural dimensions (e.g., it's a vector graphic with no specified content size) and either *options*'s `resizeWidth`[p1121] or *options*'s `resizeHeight`[p1121] is not present, then a promise rejected

with an "InvalidStateError" DOMException.

2. If *image*'s media data has no natural dimensions (e.g., it's a vector graphics with no specified content size), it should be rendered to a bitmap of the size specified by the resizeWidth[p1121] and the resizeHeight[p1121] options.

3. Set *imageBitmap*'s bitmap data[p1121] to a copy of *image*'s media data, cropped to the source rectangle with formatting[p1123]. If this is an animated image, *imageBitmap*'s bitmap data[p1121] must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.

4. If *image* is not origin-clean[p696], then set the origin-clean[p663] flag of *imageBitmap*'s bitmap to false.

5. Run this step in parallel[p43]:

    1. Resolve *p* with *imageBitmap*.

↪ **video**[p398]

1. If *image*'s networkState[p410] attribute is NETWORK_EMPTY[p410], then return a promise rejected with an "InvalidStateError" DOMException.

2. Set *imageBitmap*'s bitmap data[p1121] to a copy of the frame at the current playback position[p423], at the media resource[p407]'s natural width[p401] and natural height[p401] (i.e., after any aspect-ratio correction has been applied), cropped to the source rectangle with formatting[p1123].

3. If *image* is not origin-clean[p696], then set the origin-clean[p663] flag of *imageBitmap*'s bitmap to false.

4. Run this step in parallel[p43]:

    1. Resolve *p* with *imageBitmap*.

↪ **canvas**[p661]

1. Set *imageBitmap*'s bitmap data[p1121] to a copy of *image*'s bitmap data[p1121], cropped to the source rectangle with formatting[p1123].

2. Set the origin-clean[p663] flag of the *imageBitmap*'s bitmap to the same value as the origin-clean[p663] flag of *image*'s bitmap.

3. Run this step in parallel[p43]:

    1. Resolve *p* with *imageBitmap*.

↪ **Blob**

Run these step in parallel[p43]:

1. Let *imageData* be the result of reading *image*'s data. If an error occurs during reading of the object[p60], then reject *p* with an "InvalidStateError" DOMException and abort these steps.

2. Apply the image sniffing rules to determine the file format of *imageData*, with MIME type of *image* (as given by *image*'s type attribute) giving the official type.

3. If *imageData* is not in a supported image file format (e.g., it's not an image at all), or if *imageData* is corrupted in some fatal way such that the image dimensions cannot be obtained (e.g., a vector graphic with no natural size), then reject *p* with an "InvalidStateError" DOMException and abort these steps.

4. Set *imageBitmap*'s bitmap data[p1121] to *imageData*, cropped to the source rectangle with formatting[p1123]. If this is an animated image, *imageBitmap*'s bitmap data[p1121] must only be taken from the default image of the animation (the one that the format defines is to be used when animation is not supported or is disabled), or, if there is no such image, the first frame of the animation.

5. Resolve *p* with *imageBitmap*.

↪ **ImageData**[p670]

1. Let *buffer* be *image*'s data[p711] attribute value's [[ViewedArrayBuffer]] internal slot.

2. If IsDetachedBuffer(*buffer*) is true, then return a promise rejected with an "InvalidStateError" DOMException.

3. Set *imageBitmap*'s bitmap data[p1121] to *image*'s image data, cropped to the source rectangle with formatting[p1123].

4. Run this step in parallel[p43]:

    1. Resolve *p* with *imageBitmap*.

↪ **ImageBitmap**[p1120]

1. Set *imageBitmap*'s bitmap data[p1121] to a copy of *image*'s bitmap data[p1121], cropped to the source rectangle with formatting[p1123].

2. Set the origin-clean[p663] flag of *imageBitmap*'s bitmap to the same value as the origin-clean[p663] flag of *image*'s bitmap.

3. Run this step in parallel[p43]:

    1. Resolve *p* with *imageBitmap*.

↪ **VideoFrame**

1. Set *imageBitmap*'s bitmap data[p1121] to a copy of *image*'s visible pixel data, cropped to the source rectangle with formatting[p1123].

2. Run this step in parallel[p43]:

    1. Resolve *p* with *imageBitmap*.

7. Return *p*.

When the steps above require that the user agent **crop bitmap data to the source rectangle with formatting**, the user agent must run the following steps:

1. Let *input* be the bitmap data[p1121] being transformed.

2. If *sx*, *sy*, *sw* and *sh* are specified, let *sourceRectangle* be a rectangle whose corners are the four points (*sx*, *sy*), (*sx*+*sw*, *sy*),(*sx*+*sw*, *sy*+*sh*), (*sx*,*sy*+*sh*). Otherwise let *sourceRectangle* be a rectangle whose corners are the four points (0,0), (width of *input*, 0), (width of *input*, height of *input*), (0, height of *input*).

    Note

    If either sw *or* sh *are negative, then the top-left corner of this rectangle will be to the left or above the (*sx, sy*) point.*

3. Let *outputWidth* be determined as follows:

    ↪ **If the resizeWidth[p1121] member of *options* is specified**
    the value of the resizeWidth[p1121] member of *options*

    ↪ **If the resizeWidth[p1121] member of *options* is not specified, but the resizeHeight[p1121] member is specified**
    the width of *sourceRectangle*, times the value of the resizeHeight[p1121] member of *options*, divided by the height of *sourceRectangle*, rounded up to the nearest integer

    ↪ **If neither resizeWidth[p1121] nor resizeHeight[p1121] are specified**
    the width of *sourceRectangle*

4. Let *outputHeight* be determined as follows:

    ↪ **If the resizeHeight[p1121] member of *options* is specified**
    the value of the resizeHeight[p1121] member of *options*

    ↪ **If the resizeHeight[p1121] member of *options* is not specified, but the resizeWidth[p1121] member is specified**
    the height of *sourceRectangle*, times the value of the resizeWidth[p1121] member of *options*, divided by the width of *sourceRectangle*, rounded up to the nearest integer

    ↪ **If neither resizeWidth[p1121] nor resizeHeight[p1121] are specified**
    the height of *sourceRectangle*

5. Place *input* on an infinite transparent black grid plane, positioned so that its top left corner is at the origin of the plane, with the *x*-coordinate increasing to the right, and the *y*-coordinate increasing down, and with each pixel in the *input* image data occupying a cell on the plane's grid.

6. Let *output* be the rectangle on the plane denoted by *sourceRectangle*.

7. Scale *output* to the size specified by *outputWidth* and *outputHeight*. The user agent should use the value of the **resizeQuality** option to guide the choice of scaling algorithm.

8. If the value of the **imageOrientation** member of *options* is "**flipY**", *output* must be flipped vertically, disregarding any image orientation metadata of the source (such as EXIF metadata), if any. [EXIF][p1413]

   Note

   *If the value is "**from-image**", no extra step is needed.*

   Note

   *There used to be a "**none**" enum value. It was renamed to "from-image[p1124]". In the future, "none[p1124]" will be added back with a different meaning.*

9. If *image* is an img[p338] element or a Blob object, let *val* be the value of the **colorSpaceConversion** member of *options*, and then run these substeps:

   1. If *val* is "**default**", the color space conversion behavior is implementation-specific, and should be chosen according to the default color space that the implementation uses for drawing images onto the canvas.

   2. If *val* is "**none**", *output* must be decoded without performing any color space conversions. This means that the image decoding algorithm must ignore color profile metadata embedded in the source data as well as the display device color profile.

10. Let *val* be the value of **premultiplyAlpha** member of *options*, and then run these substeps:

    1. If *val* is "**default**", the alpha premultiplication behavior is implementation-specific, and should be chosen according to implementation deems optimal for drawing images onto the canvas.

    2. If *val* is "**premultiply**", the *output* that is not premultiplied by alpha must have its color components multiplied by alpha[p733] and that is premultiplied by alpha must be left untouched.

    3. If *val* is "**none**", the *output* that is not premultiplied by alpha must be left untouched and that is premultiplied by alpha must have its color components divided by alpha[p733].

11. Return *output*.

The **close()** method steps are:

1. Set this's [[Detached]][p116] internal slot value to true.

2. Unset this's bitmap data[p1121].

The **width** getter steps are:

1. If this's [[Detached]][p116] internal slot's value is true, then return 0.

2. Return this's width, in CSS pixels.

The **height** getter steps are:

1. If this's [[Detached]][p116] internal slot's value is true, then return 0.

2. Return this's height, in CSS pixels.

The ResizeQuality[p1120] enumeration is used to express a preference for the interpolation quality to use when scaling images.

The "**pixelated**" value indicates a preference to scale the image that maximizes the appearance. Scaling algorithms that "smooth" colors are acceptable, such as bilinear interpolation.

The "**low**" value indicates a preference for a low level of image interpolation quality. Low-quality image interpolation may be more computationally efficient than higher settings.

The "**medium**" value indicates a preference for a medium level of image interpolation quality.

The "**high**" value indicates a preference for a high level of image interpolation quality. High-quality image interpolation may be more

computationally expensive than lower settings.

Note

Bilinear scaling is an example of a relatively fast, lower-quality image-smoothing algorithm. Bicubic or Lanczos scaling are examples of image-scaling algorithms that produce higher-quality output. This specification does not mandate that specific interpolation algorithms be used unless the value is "pixelated[p1124]".

Example

Using this API, a sprite sheet can be precut and prepared:

```
var sprites = {};
function loadMySprites() {
  var image = new Image();
  image.src = 'mysprites.png';
  var resolver;
  var promise = new Promise(function (arg) { resolver = arg });
  image.onload = function () {
    resolver(Promise.all([
      createImageBitmap(image,  0,  0, 40, 40).then(function (image) { sprites.person = image }),
      createImageBitmap(image, 40,  0, 40, 40).then(function (image) { sprites.grass  = image }),
      createImageBitmap(image, 80,  0, 40, 40).then(function (image) { sprites.tree   = image }),
      createImageBitmap(image,  0, 40, 40, 40).then(function (image) { sprites.hut    = image }),
      createImageBitmap(image, 40, 40, 40, 40).then(function (image) { sprites.apple  = image }),
      createImageBitmap(image, 80, 40, 40, 40).then(function (image) { sprites.snake  = image })
    ]));
  };
  return promise;
}

function runDemo() {
  var canvas = document.querySelector('canvas#demo');
  var context = canvas.getContext('2d');
  context.drawImage(sprites.tree, 30, 10);
  context.drawImage(sprites.snake, 70, 10);
}

loadMySprites().then(runDemo);
```

8.11 Animation frames §[p1125]

Some objects include the AnimationFrameProvider[p1125] interface mixin.

IDL

```
callback FrameRequestCallback = undefined (DOMHighResTimeStamp time);

interface mixin AnimationFrameProvider {
  unsigned long requestAnimationFrame(FrameRequestCallback callback);
  undefined cancelAnimationFrame(unsigned long handle);
};
Window includes AnimationFrameProvider;
DedicatedWorkerGlobalScope includes AnimationFrameProvider;
```

Each AnimationFrameProvider[p1125] object also has a **target object** that stores the provider's internal state. It is defined as follows:

If the AnimationFrameProvider[p1125] is a Window[p892]

The Window[p892]'s associated Document[p894]

If the AnimationFrameProvider[p1125] is a DedicatedWorkerGlobalScope[p1168]

The DedicatedWorkerGlobalScope[p1168]

Each target object[p1125] has a **map of animation frame callbacks**, which is an ordered map that must be initially empty, and an **animation frame callback identifier**, which is a number that must initially be zero.

An `AnimationFrameProvider`[p1125] *provider* is considered **supported** if any of the following hold:

- *provider* is a `Window`[p892].
- *provider*'s owner set[p1166] contains a `Document`[p127] object.
- Any of the `DedicatedWorkerGlobalScope`[p1168] objects in *provider*'s owner set[p1166] are supported[p1126].

The **`requestAnimationFrame(callback)`** method steps are:

1. If this is not supported[p1126], then throw a `"NotSupportedError"` `DOMException`.
2. Let *target* be this's target object[p1125].
3. Increment *target*'s animation frame callback identifier[p1126] by one, and let *handle* be the result.
4. Let *callbacks* be *target*'s map of animation frame callbacks[p1126].
5. Set *callbacks*[*handle*] to *callback*.
6. Return *handle*.

The **`cancelAnimationFrame(handle)`** method steps are:

1. If this is not supported[p1126], then throw a `"NotSupportedError"` `DOMException`.
2. Let *callbacks* be this's target object[p1125]'s map of animation frame callbacks[p1126].
3. Remove *callbacks*[*handle*].

To **run the animation frame callbacks** for a target object[p1125] *target* with a timestamp *now*:

1. Let *callbacks* be *target*'s map of animation frame callbacks[p1126].
2. Let *callbackHandles* be the result of getting the keys of *callbacks*.
3. For each *handle* in *callbackHandles*, if *handle* exists in *callbacks*:
    1. Let *callback* be *callbacks*[*handle*].
    2. Remove *callbacks*[*handle*].
    3. Invoke *callback*, passing *now* as the only argument, and if an exception is thrown, report the exception[p1053].

Example

Inside workers, `requestAnimationFrame()`[p1126] can be used together with an `OffscreenCanvas`[p725] transferred from a `canvas`[p661] element. First, in the document, transfer control to the worker:

```
const offscreenCanvas = document.getElementById("c").transferControlToOffscreen();
worker.postMessage(offscreenCanvas, [offscreenCanvas]);
```

Then, in the worker, the following code will draw a rectangle moving from left to right:

```
let ctx, pos = 0;
function draw(dt) {
  ctx.clearRect(0, 0, 100, 100);
  ctx.fillRect(pos, 0, 10, 10);
  pos += 10 * dt;
  requestAnimationFrame(draw);
}

self.onmessage = function(ev) {
  const transferredCanvas = ev.data;
  ctx = transferredCanvas.getContext("2d");
```

```
  draw();
};
```

9 Communication §p1128

Note

The WebSocket *interface used to be defined here. It is now defined in* WebSockets. *[WEBSOCKETS]p1418*

9.1 The MessageEventp1128 interface §p1128

Messages in server-sent eventsp1129, cross-document messagingp1138, channel messagingp1141, broadcast channelsp1147, and *WebSockets* use the MessageEventp1128 interface for their messagep1407 events: [WEBSOCKETS]p1418

IDL

```
[Exposed=(Window,Worker,AudioWorklet)]
interface MessageEvent : Event {
  constructor(DOMString type, optional MessageEventInit eventInitDict = {});

  readonly attribute any data;
  readonly attribute USVString origin;
  readonly attribute DOMString lastEventId;
  readonly attribute MessageEventSource? source;
  readonly attribute FrozenArray<MessagePort> ports;

  undefined initMessageEvent(DOMString type, optional boolean bubbles = false, optional boolean
cancelable = false, optional any data = null, optional USVString origin = "", optional DOMString
lastEventId = "", optional MessageEventSource? source = null, optional sequence<MessagePort> ports =
[]);
};

dictionary MessageEventInit : EventInit {
  any data = null;
  USVString origin = "";
  DOMString lastEventId = "";
  MessageEventSource? source = null;
  sequence<MessagePort> ports = [];
};

typedef (WindowProxy or MessagePort or ServiceWorker) MessageEventSource;
```

For web developers (non-normative)

***event*.data**p1128

Returns the data of the message.

***event*.origin**p1129

Returns the origin of the message, for server-sent eventsp1129 and cross-document messagingp1138.

***event*.lastEventId**p1129

Returns the last event ID stringp1130, for server-sent eventsp1129.

***event*.source**p1129

Returns the WindowProxyp904 of the source window, for cross-document messagingp1138, and the MessagePortp1144 being attached, in the connectp1406 event fired at SharedWorkerGlobalScopep1168 objects.

***event*.ports**p1129

Returns the MessagePortp1144 array sent with the message, for cross-document messagingp1138 and channel messagingp1141.

The **data** attribute must return the value it was initialized to. It represents the message being sent.

The **origin** attribute must return the value it was initialized to. It represents, in server-sent events[p1129] and cross-document messaging[p1138], the origin of the document that sent the message (typically the scheme, hostname, and port of the document, but not its path or fragment).

The **lastEventId** attribute must return the value it was initialized to. It represents, in server-sent events[p1129], the last event ID string[p1130] of the event source.

The **source** attribute must return the value it was initialized to. It represents, in cross-document messaging[p1138], the WindowProxy[p904] of the browsing context[p961] of the Window[p892] object from which the message came; and in the connect[p1406] events used by shared workers[p1168], the newly connecting MessagePort[p1144].

The **ports** attribute must return the value it was initialized to. It represents, in cross-document messaging[p1138] and channel messaging[p1141], the MessagePort[p1144] array being sent.

The **initMessageEvent(*type, bubbles, cancelable, data, origin, lastEventId, source, ports*)** method must initialize the event in a manner analogous to the similarly-named initEvent() method. [DOM][p1412]

Note

Various APIs (e.g., WebSocket, EventSource[p1130]) use the MessageEvent[p1128] interface for their message[p1407] event without using the MessagePort[p1144] API.

✔ MDN

9.2 Server-sent events §[p1129]

9.2.1 Introduction §[p1129]

This section is non-normative.

To enable servers to push data to web pages over HTTP or using dedicated server-push protocols, this specification introduces the EventSource[p1130] interface.

Using this API consists of creating an EventSource[p1130] object and registering an event listener.

```
var source = new EventSource('updates.cgi');
source.onmessage = function (event) {
  alert(event.data);
};
```

On the server-side, the script ("updates.cgi" in this case) sends messages in the following form, with the text/event-stream[p1385] MIME type:

```
data: This is the first message.

data: This is the second message, it
data: has two lines.

data: This is the third message.
```

Authors can separate events by using different event types. Here is a stream that has two event types, "add" and "remove":

```
event: add
data: 73857293

event: remove
data: 2153

event: add
```

```
data: 113411
```

The script to handle such a stream would look like this (where `addHandler` and `removeHandler` are functions that take one argument, the event):

```
var source = new EventSource('updates.cgi');
source.addEventListener('add', addHandler, false);
source.addEventListener('remove', removeHandler, false);
```

The default event type is "message".

Event streams are always decoded as UTF-8. There is no way to specify another character encoding.

Event stream requests can be redirected using HTTP 301 and 307 redirects as with normal HTTP requests. Clients will reconnect if the connection is closed; a client can be told to stop reconnecting using the HTTP 204 No Content response code.

Using this API rather than emulating it using XMLHttpRequest or an iframe[p383] allows the user agent to make better use of network resources in cases where the user agent implementer and the network operator are able to coordinate in advance. Amongst other benefits, this can result in significant savings in battery life on portable devices. This is discussed further in the section below on connectionless push[p1136].

9.2.2 The EventSource[p1130] interface §[p1130]

MDN

IDL

```
[Exposed=(Window,Worker)]
interface EventSource : EventTarget {
  constructor(USVString url, optional EventSourceInit eventSourceInitDict = {});

  readonly attribute USVString url;
  readonly attribute boolean withCredentials;

  // ready state
  const unsigned short CONNECTING = 0;
  const unsigned short OPEN = 1;
  const unsigned short CLOSED = 2;
  readonly attribute unsigned short readyState;

  // networking
  attribute EventHandler onopen;
  attribute EventHandler onmessage;
  attribute EventHandler onerror;
  undefined close();
};

dictionary EventSourceInit {
  boolean withCredentials = false;
};
```

Each EventSource[p1130] object has the following associated with it:

- A **url** (a URL record). Set during construction.
- A **request**. This must initially be null.
- A **reconnection time**, in milliseconds. This must initially be an implementation-defined value, probably in the region of a few seconds.
- A **last event ID string**. This must initially be the empty string.

Apart from url[p1130] these are not currently exposed on the EventSource[p1130] object.

For web developers (non-normative)

***source* = new EventSource[p1131](*url* [, { withCredentials[p1130]: true }])**

Creates a new EventSource[p1130] object.

url is a string giving the URL that will provide the event stream.

Setting withCredentials[p1130] to true will set the credentials mode for connection requests to *url* to "include".

***source*.close[p1132]()**

Aborts any instances of the fetch algorithm started for this EventSource[p1130] object, and sets the readyState[p1132] attribute to CLOSED[p1132].

***source*.url[p1132]**

Returns the URL providing the event stream[p1130].

***source*.withCredentials[p1132]**

Returns true if the credentials mode for connection requests to the URL providing the event stream[p1130] is set to "include", and false otherwise.

***source*.readyState[p1132]**

Returns the state of this EventSource[p1130] object's connection. It can have the values described below.

The **EventSource(*url*, *eventSourceInitDict*)** constructor, when invoked, must run these steps:

1. Let *ev* be a new EventSource[p1130] object.
2. Let *settings* be *ev*'s relevant settings object[p1039].
3. Let *urlRecord* be the result of parsing *url* with *settings*'s API base URL[p1032] and *settings*'s API URL character encoding[p1032].
4. If *urlRecord* is failure, then throw a "SyntaxError" DOMException.
5. Set *ev*'s url[p1130] to *urlRecord*.
6. Let *corsAttributeState* be Anonymous[p97].
7. If the value of *eventSourceInitDict*'s withCredentials[p1130] member is true, then set *corsAttributeState* to Use Credentials[p97] and set *ev*'s withCredentials[p1132] attribute to true.
8. Let *request* be the result of creating a potential-CORS request[p96] given *urlRecord*, the empty string, and *corsAttributeState*.
9. Set *request*'s client to *settings*.
10. User agents may set (`Accept`, `text/event-stream`[p1385]) in *request*'s header list.
11. Set *request*'s cache mode to "no-store".
12. Set *request*'s initiator type to "other".
13. Set *ev*'s request[p1130] to *request*.
14. Let *processEventSourceEndOfBody* given response *res* be the following step: if *res* is not a network error, then reestablish the connection[p1132].
15. Fetch *request*, with *processResponseEndOfBody* set to *processEventSourceEndOfBody* and *processResponse* set to the following steps given response *res*:
    1. If *res* is an aborted network error, then fail the connection[p1133].
    2. Otherwise, if *res* is a network error, then reestablish the connection[p1132], unless the user agent knows that to be futile, in which case the user agent may fail the connection[p1133].
    3. Otherwise, if *res*'s status is not 200, or if *res*'s `Content-Type`[p96] is not `text/event-stream`[p1385], then fail the connection[p1133].
    4. Otherwise, announce the connection[p1132] and interpret[p1134] *res*'s body line by line.
16. Return *ev*.

The **`url`** attribute's getter must return the serialization of this EventSource[p1130] object's url[p1130].

The **`withCredentials`** attribute must return the value to which it was last initialized. When the object is created, it must be initialized to false.

The **`readyState`** attribute represents the state of the connection. It can have the following values:

`CONNECTING` (numeric value 0)

The connection has not yet been established, or it was closed and the user agent is reconnecting.

`OPEN` (numeric value 1)

The user agent has an open connection and is dispatching events as it receives them.

`CLOSED` (numeric value 2)

The connection is not open, and the user agent is not trying to reconnect. Either there was a fatal error or the `close()`[p1132] method was invoked.

When the object is created its `readyState`[p1132] must be set to `CONNECTING`[p1132] (0). The rules given below for handling the connection define when the value changes.

The **`close()`** method must abort any instances of the fetch algorithm started for this EventSource[p1130] object, and must set the `readyState`[p1132] attribute to `CLOSED`[p1132].

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported, as event handler IDL attributes[p1084], by all objects implementing the EventSource[p1130] interface:

Event handler[p1083]	Event handler event type[p1085]
`onopen`	`open`[p1407]
`onmessage`	`message`[p1407]
`onerror`	`error`[p1406]

9.2.3 Processing model §[p1132]

When a user agent is to **announce the connection**, the user agent must queue a task[p1072] which, if the `readyState`[p1132] attribute is set to a value other than `CLOSED`[p1132], sets the `readyState`[p1132] attribute to `OPEN`[p1132] and fires an event named `open`[p1407] at the EventSource[p1130] object.

When a user agent is to **reestablish the connection**, the user agent must run the following steps. These steps are run in parallel[p43], not as part of a task[p1071]. (The tasks that it queues, of course, are run like normal tasks and not themselves in parallel[p43].)

1. Queue a task[p1072] to run the following steps:
    1. If the `readyState`[p1132] attribute is set to `CLOSED`[p1132], abort the task.
    2. Set the `readyState`[p1132] attribute to `CONNECTING`[p1132].
    3. Fire an event named `error`[p1406] at the EventSource[p1130] object.
2. Wait a delay equal to the reconnection time of the event source.
3. Optionally, wait some more. In particular, if the previous attempt failed, then user agents might introduce an exponential backoff delay to avoid overloading a potentially already overloaded server. Alternatively, if the operating system has reported that there is no network connectivity, user agents might wait for the operating system to announce that the network connection has returned before retrying.
4. Wait until the aforementioned task has run, if it has not yet run.
5. Queue a task[p1072] to run the following steps:
    1. If the EventSource[p1130] object's `readyState`[p1132] attribute is not set to `CONNECTING`[p1132], then return.
    2. Let *request* be the EventSource[p1130] object's request[p1130].
    3. If the EventSource[p1130] object's last event ID string[p1130] is not the empty string, then:

1. Let *lastEventIDValue* be the EventSource[p1130] object's last event ID string[p1130], encoded as UTF-8.

2. Set (`Last-Event-ID[p1133]`, *lastEventIDValue*) in *request*'s header list.

4. Fetch *request* and process the response obtained in this fashion, if any, as described earlier in this section.

When a user agent is to **fail the connection**, the user agent must queue a task[p1072] which, if the readyState[p1132] attribute is set to a value other than CLOSED[p1132], sets the readyState[p1132] attribute to CLOSED[p1132] and fires an event named error[p1406] at the EventSource[p1130] object. **Once the user agent has failed the connection[p1133], it does *not* attempt to reconnect.**

The task source[p1072] for any tasks[p1071] that are queued[p1072] by EventSource[p1130] objects is the **remote event task source**.

9.2.4 The `Last-Event-ID[p1133]` header §[p1133]

The **`Last-Event-ID`** HTTP request header reports an EventSource[p1130] object's last event ID string[p1130] to the server when the user agent is to reestablish the connection[p1132].

See whatwg/html issue #7363 to define the value space better. It is essentially any UTF-8 encoded string, that does not contain U+0000 NULL, U+000A LF, or U+000D CR.

9.2.5 Parsing an event stream §[p1133]

This event stream format's MIME type is text/event-stream[p1385].

The event stream format is as described by the `stream` production of the following ABNF, the character set for which is Unicode. [ABNF][p1410]

```
stream        = [ bom ] *event
event         = *( comment / field ) end-of-line
comment       = colon *any-char end-of-line
field         = 1*name-char [ colon [ space ] *any-char ] end-of-line
end-of-line   = ( cr lf / cr / lf )

; characters
lf            = %x000A ; U+000A LINE FEED (LF)
cr            = %x000D ; U+000D CARRIAGE RETURN (CR)
space         = %x0020 ; U+0020 SPACE
colon         = %x003A ; U+003A COLON (:)
bom           = %xFEFF ; U+FEFF BYTE ORDER MARK
name-char     = %x0000-0009 / %x000B-000C / %x000E-0039 / %x003B-10FFFF
                ; a scalar value other than U+000A LINE FEED (LF), U+000D CARRIAGE RETURN (CR), or
U+003A COLON (:)
any-char      = %x0000-0009 / %x000B-000C / %x000E-10FFFF
                ; a scalar value other than U+000A LINE FEED (LF) or U+000D CARRIAGE RETURN (CR)
```

Event streams in this format must always be encoded as UTF-8. [ENCODING][p1413]

Lines must be separated by either a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character, or a single U+000D CARRIAGE RETURN (CR) character.

Since connections established to remote servers for such resources are expected to be long-lived, UAs should ensure that appropriate buffering is used. In particular, while line buffering with lines are defined to end with a single U+000A LINE FEED (LF) character is safe, block buffering or line buffering with different expected line endings can cause delays in event dispatch.

9.2.6 Interpreting an event stream §p11 34

Streams must be decoded using the UTF-8 decode algorithm.

Note

The UTF-8 decode algorithm strips one leading UTF-8 Byte Order Mark (BOM), if any.

The stream must then be parsed by reading everything line by line, with a U+000D CARRIAGE RETURN U+000A LINE FEED (CRLF) character pair, a single U+000A LINE FEED (LF) character not preceded by a U+000D CARRIAGE RETURN (CR) character, and a single U+000D CARRIAGE RETURN (CR) character not followed by a U+000A LINE FEED (LF) character being the ways in which a line can end.

When a stream is parsed, a *data* buffer, an *event type* buffer, and a *last event ID* buffer must be associated with it. They must be initialized to the empty string.

Lines must be processed, in the order they are received, as follows:

↪ **If the line is empty (a blank line)**

Dispatch the event p1134, as defined below.

↪ **If the line starts with a U+003A COLON character (:)**

Ignore the line.

↪ **If the line contains a U+003A COLON character (:)**

Collect the characters on the line before the first U+003A COLON character (:), and let *field* be that string.

Collect the characters on the line after the first U+003A COLON character (:), and let *value* be that string. If *value* starts with a U+0020 SPACE character, remove it from *value*.

Process the field p1134 using the steps described below, using *field* as the field name and *value* as the field value.

↪ **Otherwise, the string is not empty but does not contain a U+003A COLON character (:)**

Process the field p1134 using the steps described below, using the whole line as the field name, and the empty string as the field value.

Once the end of the file is reached, any pending data must be discarded. (If the file ends in the middle of an event, before the final empty line, the incomplete event is not dispatched.)

The steps to **process the field** given a field name and a field value depend on the field name, as given in the following list. Field names must be compared literally, with no case folding performed.

↪ **If the field name is "event"**

Set the *event type* buffer to field value.

↪ **If the field name is "data"**

Append the field value to the *data* buffer, then append a single U+000A LINE FEED (LF) character to the *data* buffer.

↪ **If the field name is "id"**

If the field value does not contain U+0000 NULL, then set the *last event ID* buffer to the field value. Otherwise, ignore the field.

↪ **If the field name is "retry"**

If the field value consists of only ASCII digits, then interpret the field value as an integer in base ten, and set the event stream's reconnection time p1130 to that integer. Otherwise, ignore the field.

↪ **Otherwise**

The field is ignored.

When the user agent is required to **dispatch the event**, the user agent must process the *data* buffer, the *event type* buffer, and the *last event ID* buffer using steps appropriate for the user agent.

For web browsers, the appropriate steps to dispatch the event p1134 are as follows:

1. Set the last event ID string p1130 of the event source to the value of the *last event ID* buffer. The buffer does not get reset, so

the last event ID string[p1130] of the event source remains set to this value until the next time it is set by the server.

2. If the *data* buffer is an empty string, set the *data* buffer and the *event type* buffer to the empty string and return.

3. If the *data* buffer's last character is a U+000A LINE FEED (LF) character, then remove the last character from the *data* buffer.

4. Let *event* be the result of creating an event using `MessageEvent`[p1128], in the relevant realm[p1039] of the `EventSource`[p1130] object.

5. Initialize *event*'s `type` attribute to "`message`[p1407]", its `data`[p1128] attribute to *data*, its `origin`[p1129] attribute to the serialization[p869] of the origin of the event stream's final URL (i.e., the URL after redirects), and its `lastEventId`[p1129] attribute to the last event ID string[p1130] of the event source.

6. If the *event type* buffer has a value other than the empty string, change the type of the newly created event to equal the value of the *event type* buffer.

7. Set the *data* buffer and the *event type* buffer to the empty string.

8. Queue a task[p1072] which, if the `readyState`[p1132] attribute is set to a value other than `CLOSED`[p1132], dispatches the newly created event at the `EventSource`[p1130] object.

Note

If an event doesn't have an "id" field, but an earlier event did set the event source's last event ID string[p1130], then the event's `lastEventId`[p1129] field will be set to the value of whatever the last seen "id" field was.

For other user agents, the appropriate steps to dispatch the event[p1134] are implementation dependent, but at a minimum they must set the *data* and *event type* buffers to the empty string before returning.

Example

The following event stream, once followed by a blank line:

```
data: YHOO
data: +2
data: 10
```

...would cause an event `message`[p1407] with the interface `MessageEvent`[p1128] to be dispatched on the `EventSource`[p1130] object. The event's `data`[p1128] attribute would contain the string "`YHOO\n+2\n10`" (where "`\n`" represents a newline).

This could be used as follows:

```
var stocks = new EventSource("https://stocks.example.com/ticker.php");
stocks.onmessage = function (event) {
  var data = event.data.split('\n');
  updateStocks(data[0], data[1], data[2]);
};
```

...where `updateStocks()` is a function defined as:

```
function updateStocks(symbol, delta, value) { ... }
```

...or some such.

Example

The following stream contains four blocks. The first block has just a comment, and will fire nothing. The second block has two fields with names "data" and "id" respectively; an event will be fired for this block, with the data "first event", and will then set the last event ID to "1" so that if the connection died between this block and the next, the server would be sent a `` `Last-Event-ID`[p1133] `` header with the value `` `1` ``. The third block fires an event with data "second event", and also has an "id" field, this time with no value, which resets the last event ID to the empty string (meaning no `` `Last-Event-ID`[p1133] `` header will now be sent in the event of a reconnection being attempted). Finally, the last block just fires an event with the data " third event" (with a single leading space character). Note that the last still has to end with a blank line, the end of the stream is not enough to trigger the dispatch of the last event.

```
: test stream

data: first event
id: 1

data:second event
id

data:  third event
```

Example

The following stream fires two events:

```
data

data
data

data:
```

The first block fires events with the data set to the empty string, as would the last block if it was followed by a blank line. The middle block fires an event with the data set to a single newline character. The last block is discarded because it is not followed by a blank line.

Example

The following stream fires two identical events:

```
data:test

data: test
```

This is because the space after the colon is ignored if present.

9.2.7 Authoring notes §p1136

Legacy proxy servers are known to, in certain cases, drop HTTP connections after a short timeout. To protect against such proxy servers, authors can include a comment line (one starting with a ':' character) every 15 seconds or so.

Authors wishing to relate event source connections to each other or to specific documents previously served might find that relying on IP addresses doesn't work, as individual clients can have multiple IP addresses (due to having multiple proxy servers) and individual IP addresses can have multiple clients (due to sharing a proxy server). It is better to include a unique identifier in the document when it is served and then pass that identifier as part of the URL when the connection is established.

Authors are also cautioned that HTTP chunking can have unexpected negative effects on the reliability of this protocol, in particular if the chunking is done by a different layer unaware of the timing requirements. If this is a problem, chunking can be disabled for serving event streams.

Clients that support HTTP's per-server connection limitation might run into trouble when opening multiple pages from a site if each page has an EventSource p1130 to the same domain. Authors can avoid this using the relatively complex mechanism of using unique domain names per connection, or by allowing the user to enable or disable the EventSource p1130 functionality on a per-page basis, or by sharing a single EventSource p1130 object using a shared worker p1168.

9.2.8 Connectionless push and other features §p1136

User agents running in controlled environments, e.g. browsers on mobile handsets tied to specific carriers, may offload the management of the connection to a proxy on the network. In such a situation, the user agent for the purposes of conformance is

considered to include both the handset software and the network proxy.

Example

For example, a browser on a mobile device, after having established a connection, might detect that it is on a supporting network and request that a proxy server on the network take over the management of the connection. The timeline for such a situation might be as follows:

1. Browser connects to a remote HTTP server and requests the resource specified by the author in the EventSource[p1131] constructor.
2. The server sends occasional messages.
3. In between two messages, the browser detects that it is idle except for the network activity involved in keeping the TCP connection alive, and decides to switch to sleep mode to save power.
4. The browser disconnects from the server.
5. The browser contacts a service on the network, and requests that the service, a "push proxy", maintain the connection instead.
6. The "push proxy" service contacts the remote HTTP server and requests the resource specified by the author in the EventSource[p1131] constructor (possibly including a `Last-Event-ID[p1133]` HTTP header, etc.).
7. The browser allows the mobile device to go to sleep.
8. The server sends another message.
9. The "push proxy" service uses a technology such as OMA push to convey the event to the mobile device, which wakes only enough to process the event and then returns to sleep.

This can reduce the total data usage, and can therefore result in considerable power savings.

As well as implementing the existing API and text/event-stream[p1385] wire format as defined by this specification and in more distributed ways as described above, formats of event framing defined by other applicable specifications[p70] may be supported. This specification does not define how they are to be parsed or processed.

9.2.9 Garbage collection §[p1137]

While an EventSource[p1130] object's readyState[p1132] is CONNECTING[p1132], and the object has one or more event listeners registered for open[p1407], message[p1407] or error[p1406] events, there must be a strong reference from the Window[p892] or WorkerGlobalScope[p1166] object that the EventSource[p1130] object's constructor was invoked from to the EventSource[p1130] object itself.

While an EventSource[p1130] object's readyState[p1132] is OPEN[p1132], and the object has one or more event listeners registered for message[p1407] or error[p1406] events, there must be a strong reference from the Window[p892] or WorkerGlobalScope[p1166] object that the EventSource[p1130] object's constructor was invoked from to the EventSource[p1130] object itself.

While there is a task queued by an EventSource[p1130] object on the remote event task source[p1133], there must be a strong reference from the Window[p892] or WorkerGlobalScope[p1166] object that the EventSource[p1130] object's constructor was invoked from to that EventSource[p1130] object.

If a user agent is to **forcibly close** an EventSource[p1130] object (this happens when a Document[p127] object goes away permanently), the user agent must abort any instances of the fetch algorithm started for this EventSource[p1130] object, and must set the readyState[p1132] attribute to CLOSED[p1132].

If an EventSource[p1130] object is garbage collected while its connection is still open, the user agent must abort any instance of the fetch algorithm opened by this EventSource[p1130].

9.2.10 Implementation advice §[p1137]

This section is non-normative.

User agents are strongly urged to provide detailed diagnostic information about EventSource[p1130] objects and their related network connections in their development consoles, to aid authors in debugging code using this API.

For example, a user agent could have a panel displaying all the EventSource[p1130] objects a page has created, each listing the constructor's arguments, whether there was a network error, what the CORS status of the connection is and what headers were sent by the client and received from the server to lead to that status, the messages that were received and how they were parsed, and so forth.

Implementations are especially encouraged to report detailed information to their development consoles whenever an error[p1406] event is fired, since little to no information can be made available in the events themselves.

9.3 Cross-document messaging §[p1138]

Web browsers, for security and privacy reasons, prevent documents in different domains from affecting each other; that is, cross-site scripting is disallowed.

While this is an important security feature, it prevents pages from different domains from communicating even when those pages are not hostile. This section introduces a messaging system that allows documents to communicate with each other regardless of their source domain, in a way designed to not enable cross-site scripting attacks.

Note

The postMessage()[p1140] API can be used as a tracking vector.

9.3.1 Introduction §[p1138]

This section is non-normative.

Example

For example, if document A contains an iframe[p383] element that contains document B, and script in document A calls postMessage()[p1140] on the Window[p892] object of document B, then a message event will be fired on that object, marked as originating from the Window[p892] of document A. The script in document A might look like:

```
var o = document.getElementsByTagName('iframe')[0];
o.contentWindow.postMessage('Hello world', 'https://b.example.org/');
```

To register an event handler for incoming events, the script would use `addEventListener()` (or similar mechanisms). For example, the script in document B might look like:

```
window.addEventListener('message', receiver, false);
function receiver(e) {
  if (e.origin == 'https://example.com') {
    if (e.data == 'Hello world') {
      e.source.postMessage('Hello', e.origin);
    } else {
      alert(e.data);
    }
  }
}
```

This script first checks the domain is the expected domain, and then looks at the message, which it either displays to the user, or responds to by sending a message back to the document which sent the message in the first place.

9.3.2 Security §p1139

9.3.2.1 Authors §p1139

⚠Warning!

Use of this API requires extra care to protect users from hostile entities abusing a site for their own purposes.

Authors should check the `origin`p1129 attribute to ensure that messages are only accepted from domains that they expect to receive messages from. Otherwise, bugs in the author's message handling code could be exploited by hostile sites.

Furthermore, even after checking the `origin`p1129 attribute, authors should also check that the data in question is of the expected format. Otherwise, if the source of the event has been attacked using a cross-site scripting flaw, further unchecked processing of information sent using the `postMessage()`p1140 method could result in the attack being propagated into the receiver.

Authors should not use the wildcard keyword (*) in the *targetOrigin* argument in messages that contain any confidential information, as otherwise there is no way to guarantee that the message is only delivered to the recipient to which it was intended.

Authors who accept messages from any origin are encouraged to consider the risks of a denial-of-service attack. An attacker could send a high volume of messages; if the receiving page performs expensive computation or causes network traffic to be sent for each such message, the attacker's message could be multiplied into a denial-of-service attack. Authors are encouraged to employ rate limiting (only accepting a certain number of messages per minute) to make such attacks impractical.

9.3.2.2 User agents §p1139

The integrity of this API is based on the inability for scripts of one originp869 to post arbitrary events (using `dispatchEvent()` or otherwise) to objects in other origins (those that are not the samep870).

Note

Implementers are urged to take extra care in the implementation of this feature. It allows authors to transmit information from one domain to another domain, which is normally disallowed for security reasons. It also requires that UAs be careful to allow access to certain properties but not others.

User agents are also encouraged to consider rate-limiting message traffic between different originsp869, to protect naïve sites from denial-of-service attacks.

9.3.3 Posting messages §p1139

For web developers (non-normative)

***window*.postMessage**p1140**(*message* [, *options*])**

Posts a message to the given window. Messages can be structured objects, e.g. nested objects and arrays, can contain JavaScript values (strings, numbers, `Date` objects, etc.), and can contain certain data objects such as `File` `Blob`, `FileList`, and `ArrayBuffer` objects.

Objects listed in the `transfer`p1144 member of *options* are transferred, not just cloned, meaning that they are no longer usable on the sending side.

A target origin can be specified using the `targetOrigin`p893 member of *options*. If not provided, it defaults to "/". This default restricts the message to same-origin targets only.

If the origin of the target window doesn't match the given target origin, the message is discarded, to avoid information leakage. To send the message to the target regardless of origin, set the target origin to "*".

Throws a "`DataCloneError`" `DOMException` if *transfer* array contains duplicate objects or if *message* could not be cloned.

***window*.postMessage**p1140**(*message*, *targetOrigin* [, *transfer*])**

This is an alternate version of `postMessage()`p1140 where the target origin is specified as a parameter. Calling `window.postMessage(message, target, transfer)` is equivalent to `window.postMessage(message, {targetOrigin, transfer})`.

Note

When posting a message to a Window[p892] of a browsing context[p961] that has just been navigated to a new Document[p127] is likely to result in the message not receiving its intended recipient: the scripts in the target browsing context[p961] have to have had time to set up listeners for the messages. Thus, for instance, in situations where a message is to be sent to the Window[p892] of newly created child iframe[p383], authors are advised to have the child Document[p127] post a message to their parent announcing their readiness to receive messages, and for the parent to wait for this message before beginning posting messages.

The **window post message steps**, given a *targetWindow*, *message*, and *options*, are as follows:

1. Let *targetRealm* be *targetWindow*'s realm[p1033].
2. Let *incumbentSettings* be the incumbent settings object[p1036].
3. Let *targetOrigin* be *options*["targetOrigin[p893]"].
4. If *targetOrigin* is a single U+002F SOLIDUS character (/), then set *targetOrigin* to *incumbentSettings*'s origin[p1032].
5. Otherwise, if *targetOrigin* is not a single U+002A ASTERISK character (*), then:
    1. Let *parsedURL* be the result of running the URL parser on *targetOrigin*.
    2. If *parsedURL* is failure, then throw a "SyntaxError" DOMException.
    3. Set *targetOrigin* to *parsedURL*'s origin.
6. Let *transfer* be *options*["transfer[p1144]"].
7. Let *serializeWithTransferResult* be StructuredSerializeWithTransfer[p123](*message*, *transfer*). Rethrow any exceptions.
8. Queue a global task[p1073] on the **posted message task source** given *targetWindow* to run the following steps:
    1. If the *targetOrigin* argument is not a single literal U+002A ASTERISK character (*) and *targetWindow*'s associated Document[p894]'s origin is not same origin[p870] with *targetOrigin*, then return.
    2. Let *origin* be the serialization[p869] of *incumbentSettings*'s origin[p1032].
    3. Let *source* be the WindowProxy[p904] object corresponding to *incumbentSettings*'s global object[p1033] (a Window[p892] object).
    4. Let *deserializeRecord* be StructuredDeserializeWithTransfer[p124](*serializeWithTransferResult*, *targetRealm*).

       If this throws an exception, catch it, fire an event named messageerror[p1407] at *targetWindow*, using MessageEvent[p1128], with the origin[p1129] attribute initialized to *origin* and the source[p1129] attribute initialized to *source*, and then return.
    5. Let *messageClone* be *deserializeRecord*.[[Deserialized]].
    6. Let *newPorts* be a new frozen array consisting of all MessagePort[p1144] objects in *deserializeRecord*.[[TransferredValues]], if any, maintaining their relative order.
    7. Fire an event named message[p1407] at *targetWindow*, using MessageEvent[p1128], with the origin[p1129] attribute initialized to *origin*, the source[p1129] attribute initialized to *source*, the data[p1128] attribute initialized to *messageClone*, and the ports[p1129] attribute initialized to *newPorts*.

The Window[p892] interface's **postMessage(*message, options*)** method steps are to run the window post message steps[p1140] given this, *message*, and *options*.

The Window[p892] interface's **postMessage(*message, targetOrigin, transfer*)** method steps are to run the window post message steps[p1140] given this, *message*, and «["targetOrigin[p893]" → *targetOrigin*, "transfer[p1144]" → *transfer*]».

9.4 Channel messaging §p1141

9.4.1 Introduction §p1141

This section is non-normative.

To enable independent pieces of code (e.g. running in different browsing contexts[p961]) to communicate directly, authors can use channel messaging[p1141].

Communication channels in this mechanism are implemented as two-ways pipes, with a port at each end. Messages sent in one port are delivered at the other port, and vice-versa. Messages are delivered as DOM events, without interrupting or blocking running tasks[p1071].

To create a connection (two "entangled" ports), the `MessageChannel()` constructor is called:

```
var channel = new MessageChannel();
```

One of the ports is kept as the local port, and the other port is sent to the remote code, e.g. using `postMessage()`[p1140]:

```
otherWindow.postMessage('hello', 'https://example.com', [channel.port2]);
```

To send messages, the `postMessage()`[p1146] method on the port is used:

```
channel.port1.postMessage('hello');
```

To receive messages, one listens to `message`[p1407] events:

```
channel.port1.onmessage = handleMessage;
function handleMessage(event) {
  // message is in event.data
  // ...
}
```

Data sent on a port can be structured data; for example here an array of strings is passed on a `MessagePort`[p1144]:

```
port1.postMessage(['hello', 'world']);
```

9.4.1.1 Examples §p1141

This section is non-normative.

Example

In this example, two JavaScript libraries are connected to each other using `MessagePort`[p1144]s. This allows the libraries to later be hosted in different frames, or in `Worker`[p1174] objects, without any change to the APIs.

```
<script src="contacts.js"></script> <!-- exposes a contacts object -->
<script src="compose-mail.js"></script> <!-- exposes a composer object -->
<script>
 var channel = new MessageChannel();
 composer.addContactsProvider(channel.port1);
 contacts.registerConsumer(channel.port2);
</script>
```

Here's what the "addContactsProvider()" function's implementation could look like:

```
function addContactsProvider(port) {
  port.onmessage = function (event) {
    switch (event.data.messageType) {
      case 'search-result': handleSearchResult(event.data.results); break;
      case 'search-done': handleSearchDone(); break;
      case 'search-error': handleSearchError(event.data.message); break;
      // ...
    }
  };
};
```

Alternatively, it could be implemented as follows:

```
function addContactsProvider(port) {
  port.addEventListener('message', function (event) {
    if (event.data.messageType == 'search-result')
      handleSearchResult(event.data.results);
  });
  port.addEventListener('message', function (event) {
    if (event.data.messageType == 'search-done')
      handleSearchDone();
  });
  port.addEventListener('message', function (event) {
    if (event.data.messageType == 'search-error')
      handleSearchError(event.data.message);
  });
  // ...
  port.start();
};
```

The key difference is that when using `addEventListener()`, the `start()` p1146 method must also be invoked. When using `onmessage` p1146, the call to `start()` p1146 is implied.

The `start()` p1146 method, whether called explicitly or implicitly (by setting `onmessage` p1146), starts the flow of messages: messages posted on message ports are initially paused, so that they don't get dropped on the floor before the script has had a chance to set up its handlers.

9.4.1.2 Ports as the basis of an object-capability model on the web §p1142

This section is non-normative.

Ports can be viewed as a way to expose limited capabilities (in the object-capability model sense) to other actors in the system. This can either be a weak capability system, where the ports are merely used as a convenient model within a particular origin, or as a strong capability model, where they are provided by one origin *provider* as the only mechanism by which another origin *consumer* can effect change in or obtain information from *provider*.

For example, consider a situation in which a social web site embeds in one `iframe` p383 the user's email contacts provider (an address book site, from a second origin), and in a second `iframe` p383 a game (from a third origin). The outer social site and the game in the second `iframe` p383 cannot access anything inside the first `iframe` p383; together they can only:

- Navigate p977 the `iframe` p383 to a new URL, such as the same URL but with a different fragment, causing the `Window` p892 in the `iframe` p383 to receive a `hashchange` p1406 event.
- Resize the `iframe` p383, causing the `Window` p892 in the `iframe` p383 to receive a `resize` event.
- Send a `message` p1407 event to the `Window` p892 in the `iframe` p383 using the `window.postMessage()` p1140 API.

The contacts provider can use these methods, most particularly the third one, to provide an API that can be accessed by other origins to manipulate the user's address book. For example, it could respond to a message "`add-contact Guillaume Tell <tell@pomme.example.net>`" by adding the given person and email address to the user's address book.

To avoid any site on the web being able to manipulate the user's contacts, the contacts provider might only allow certain trusted sites,

such as the social site, to do this.

Now suppose the game wanted to add a contact to the user's address book, and that the social site was willing to allow it to do so on its behalf, essentially "sharing" the trust that the contacts provider had with the social site. There are several ways it could do this; most simply, it could just proxy messages between the game site and the contacts site. However, this solution has a number of difficulties: it requires the social site to either completely trust the game site not to abuse the privilege, or it requires that the social site verify each request to make sure it's not a request that it doesn't want to allow (such as adding multiple contacts, reading the contacts, or deleting them); it also requires some additional complexity if there's ever the possibility of multiple games simultaneously trying to interact with the contacts provider.

Using message channels and MessagePort[p1144] objects, however, all of these problems can go away. When the game tells the social site that it wants to add a contact, the social site can ask the contacts provider not for it to add a contact, but for the *capability* to add a single contact. The contacts provider then creates a pair of MessagePort[p1144] objects, and sends one of them back to the social site, who forwards it on to the game. The game and the contacts provider then have a direct connection, and the contacts provider knows to only honor a single "add contact" request, nothing else. In other words, the game has been granted the capability to add a single contact.

9.4.1.3 Ports as the basis of abstracting out service implementations §[p1143]

This section is non-normative.

Continuing the example from the previous section, consider the contacts provider in particular. While an initial implementation might have simply used XMLHttpRequest objects in the service's iframe[p383], an evolution of the service might instead want to use a shared worker[p1176] with a single WebSocket connection.

If the initial design used MessagePort[p1144] objects to grant capabilities, or even just to allow multiple simultaneous independent sessions, the service implementation can switch from the XMLHttpRequests-in-each-iframe[p383] model to the shared-WebSocket model without changing the API at all: the ports on the service provider side can all be forwarded to the shared worker without it affecting the users of the API in the slightest.

9.4.2 Message channels §[p1143]

MDN

IDL
```
[Exposed=(Window,Worker)]
interface MessageChannel {
  constructor();

  readonly attribute MessagePort port1;
  readonly attribute MessagePort port2;
};
```

For web developers (non-normative)

***channel* = new MessageChannel[p1143]()**

Returns a new MessageChannel[p1143] object with two new MessagePort[p1144] objects.

***channel*.port1[p1144]**

Returns the first MessagePort[p1144] object.

***channel*.port2[p1144]**

Returns the second MessagePort[p1144] object.

A MessageChannel[p1143] object has an associated **port 1** and an associated **port 2**, both MessagePort[p1144] objects.

The **new MessageChannel()** constructor steps are:

1. Set this's port 1[p1143] to a new MessagePort[p1144] in this's relevant realm[p1039].
2. Set this's port 2[p1143] to a new MessagePort[p1144] in this's relevant realm[p1039].
3. Entangle[p1145] this's port 1[p1143] and this's port 2[p1143].

The **port1** getter steps are to return this's port 1[p1143].

The **port2** getter steps are to return this's port 2[p1143].

9.4.3 Message ports §[p1144]

Each channel has two message ports. Data sent through one port is received by the other port, and vice versa.

IDL
```
[Exposed=(Window,Worker,AudioWorklet), Transferable]
interface MessagePort : EventTarget {
  undefined postMessage(any message, sequence<object> transfer);
  undefined postMessage(any message, optional StructuredSerializeOptions options = {});
  undefined start();
  undefined close();

  // event handlers
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};

dictionary StructuredSerializeOptions {
  sequence<object> transfer = [];
};
```

For web developers (non-normative)

***port*.postMessage[p1146](*message* [, *transfer*])**

***port*.postMessage[p1146](*message* [, { transfer }])**

Posts a message through the channel. Objects listed in *transfer* are transferred, not just cloned, meaning that they are no longer usable on the sending side.

Throws a "DataCloneError" DOMException if *transfer* contains duplicate objects or *port*, or if *message* could not be cloned.

***port*.start[p1146]()**

Begins dispatching messages received on the port.

***port*.close[p1146]()**

Disconnects the port, so that it is no longer active.

Each MessagePort[p1144] object can be entangled with another (a symmetric relationship). Each MessagePort[p1144] object also has a task source[p1072] called the **port message queue**, initially empty. A port message queue[p1144] can be enabled or disabled, and is initially disabled. Once enabled, a port can never be disabled again (though messages in the queue can get moved to another queue or removed altogether, which has much the same effect). A MessagePort[p1144] also has a **has been shipped** flag, which must initially be false.

When a port's port message queue[p1144] is enabled, the event loop[p1071] must use it as one of its task sources[p1072]. When a port's relevant global object[p1039] is a Window[p892], all tasks[p1071] queued[p1072] on its port message queue[p1144] must be associated with the port's relevant global object[p1039]'s associated Document[p894].

Note

If the document is fully active[p966], but the event listeners were all created in the context of documents that are not *fully active[p966], then the messages will not be received unless and until the documents become fully active[p966] again.*

Each event loop[p1071] has a task source[p1072] called the **unshipped port message queue**. This is a virtual task source[p1072]: it must act as if it contained the tasks[p1071] of each port message queue[p1144] of each MessagePort[p1144] whose has been shipped[p1144] flag is false, whose port message queue[p1144] is enabled, and whose relevant agent[p1029]'s event loop[p1071] is that event loop[p1071], in the order in which they were added to their respective task source[p1072]. When a task[p1071] would be removed from the unshipped port message queue[p1144], it must instead be removed from its port message queue[p1144].

When a MessagePort[p1144]'s has been shipped[p1144] flag is false, its port message queue[p1144] must be ignored for the purposes of the

event loop[p1071]. (The unshipped port message queue[p1144] is used instead.)

Note

The has been shipped[p1144] flag is set to true when a port, its twin, or the object it was cloned from, is or has been transferred. When a MessagePort[p1144]'s has been shipped[p1144] flag is true, its port message queue[p1144] acts as a first-class task source[p1072], unaffected to any unshipped port message queue[p1144].

When the user agent is to **entangle** two MessagePort[p1144] objects, it must run the following steps:

1. If one of the ports is already entangled, then disentangle it and the port that it was entangled with.

   Note

   If those two previously entangled ports were the two ports of a MessageChannel[p1143] object, then that MessageChannel[p1143] object no longer represents an actual channel: the two ports in that object are no longer entangled.

2. Associate the two ports to be entangled, so that they form the two parts of a new channel. (There is no MessageChannel[p1143] object that represents this channel.)

   Two ports *A* and *B* that have gone through this step are now said to be entangled; one is entangled to the other, and vice versa.

   Note

   While this specification describes this process as instantaneous, implementations are more likely to implement it via message passing. As with all algorithms, the key is "merely" that the end result be indistinguishable, in a black-box sense, from the specification.

MessagePort[p1144] objects are transferable objects[p115]. Their transfer steps[p116], given *value* and *dataHolder*, are:

1. Set *value*'s has been shipped[p1144] flag to true.
2. Set *dataHolder*.[[PortMessageQueue]] to *value*'s port message queue[p1144].
3. If *value* is entangled with another port *remotePort*, then:
   1. Set *remotePort*'s has been shipped[p1144] flag to true.
   2. Set *dataHolder*.[[RemotePort]] to *remotePort*.
4. Otherwise, set *dataHolder*.[[RemotePort]] to null.

Their transfer-receiving steps[p116], given *dataHolder* and *value*, are:

1. Set *value*'s has been shipped[p1144] flag to true.
2. Move all the tasks[p1071] that are to fire message[p1407] events in *dataHolder*.[[PortMessageQueue]] to the port message queue[p1144] of *value*, if any, leaving *value*'s port message queue[p1144] in its initial disabled state, and, if *value*'s relevant global object[p1039] is a Window[p892], associating the moved tasks[p1071] with *value*'s relevant global object[p1039]'s associated Document[p894].
3. If *dataHolder*.[[RemotePort]] is not null, then entangle[p1145] *dataHolder*.[[RemotePort]] and *value*. (This will disentangle *dataHolder*.[[RemotePort]] from the original port that was transferred.)

The **message port post message steps**, given *sourcePart*, *targetPort*, *message* and *options* are as follows:

1. Let *transfer* be *options*["transfer[p1144]"].
2. If *transfer* contains *sourcePort*, then throw a "DataCloneError" DOMException.
3. Let *doomed* be false.
4. If *targetPort* is not null and *transfer* contains *targetPort*, then set *doomed* to true and optionally report to a developer console that the target port was posted to itself, causing the communication channel to be lost.
5. Let *serializeWithTransferResult* be StructuredSerializeWithTransfer[p123](*message*, *transfer*). Rethrow any exceptions.

6. If *targetPort* is null, or if *doomed* is true, then return.
7. Add a task[p1071] that runs the following steps to the port message queue[p1144] of *targetPort*:
    1. Let *finalTargetPort* be the `MessagePort`[p1144] in whose port message queue[p1144] the task now finds itself.

       Note
       This can be different from targetPort*, if* targetPort *itself was transferred and thus all its tasks moved along with it.*

    2. Let *targetRealm* be *finalTargetPort*'s relevant realm[p1039].
    3. Let *deserializeRecord* be StructuredDeserializeWithTransfer[p124](*serializeWithTransferResult*, *targetRealm*).

       If this throws an exception, catch it, fire an event named `messageerror`[p1407] at *finalTargetPort*, using `MessageEvent`[p1128], and then return.

    4. Let *messageClone* be *deserializeRecord*.[[Deserialized]].
    5. Let *newPorts* be a new frozen array consisting of all `MessagePort`[p1144] objects in *deserializeRecord*.[[TransferredValues]], if any, maintaining their relative order.
    6. Fire an event named `message`[p1407] at *finalTargetPort*, using `MessageEvent`[p1128], with the `data`[p1128] attribute initialized to *messageClone* and the `ports`[p1129] attribute initialized to *newPorts*.

The **`postMessage(message, options)`** method steps are:

1. Let *targetPort* be the port with which this is entangled, if any; otherwise let it be null.
2. Run the message port post message steps[p1145] providing this, *targetPort*, *message* and *options*.

The **`postMessage(message, transfer)`** method steps are:

1. Let *targetPort* be the port with which this is entangled, if any; otherwise let it be null.
2. Let *options* be «["`transfer`[p1144]" → *transfer*]».
3. Run the message port post message steps[p1145] providing this, *targetPort*, *message* and *options*.

The **`start()`** method steps are to enable this's port message queue[p1144], if it is not already enabled.

The **`close()`** method steps are:

1. Set this's [[Detached]][p116] internal slot value to true.
2. If this is entangled, disentangle it.

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported, as event handler IDL attributes[p1084], by all objects implementing the `MessagePort`[p1144] interface:

Event handler[p1083]	Event handler event type[p1085]
`onmessage`	`message`[p1407]
`onmessageerror`	`messageerror`[p1407]

✓ MDN
✓ MDN

The first time a `MessagePort`[p1144] object's `onmessage`[p1146] IDL attribute is set, the port's port message queue[p1144] must be enabled, as if the `start()`[p1146] method had been called.

9.4.4 Broadcasting to many ports §[p1146]

This section is non-normative.

Broadcasting to many ports is in principle relatively simple: keep an array of MessagePort[p1144] objects to send messages to, and iterate through the array to send a message. However, this has one rather unfortunate effect: it prevents the ports from being garbage collected, even if the other side has gone away. To avoid this problem, implement a simple protocol whereby the other side acknowledges it still exists. If it doesn't do so after a certain amount of time, assume it's gone, close the MessagePort[p1144] object, and let it be garbage collected.

9.4.5 Ports and garbage collection §[p11 47]

When a MessagePort[p1144] object *o* is entangled, user agents must either act as if *o*'s entangled MessagePort[p1144] object has a strong reference to *o*, or as if *o*'s relevant global object[p1039] has a strong reference to *o*.

Note

Thus, a message port can be received, given an event listener, and then forgotten, and so long as that event listener could receive a message, the channel will be maintained.

Of course, if this was to occur on both sides of the channel, then both ports could be garbage collected, since they would not be reachable from live code, despite having a strong reference to each other.

Furthermore, a MessagePort[p1144] object must not be garbage collected while there exists an event referenced by a task[p1071] in a task queue[p1071] that is to be dispatched on that MessagePort[p1144] object, or while the MessagePort[p1144] object's port message queue[p1144] is enabled and not empty.

Note

Authors are strongly encouraged to explicitly close MessagePort[p1144] objects to disentangle them, so that their resources can be recollected. Creating many MessagePort[p1144] objects and discarding them without closing them can lead to high transient memory usage since garbage collection is not necessarily performed promptly, especially for MessagePort[p1144]s where garbage collection can involve cross-process coordination.

✔ MDN

9.5 Broadcasting to other browsing contexts §[p11 47]

Pages on a single origin[p869] opened by the same user in the same user agent but in different unrelated browsing contexts[p961] sometimes need to send notifications to each other, for example "hey, the user logged in over here, check your credentials again".

For elaborate cases, e.g. to manage locking of shared state, to manage synchronization of resources between a server and multiple local clients, to share a WebSocket connection with a remote host, and so forth, shared workers[p1176] are the most appropriate solution.

For simple cases, though, where a shared worker would be an unreasonable overhead, authors can use the simple channel-based broadcast mechanism described in this section.

IDL

```
[Exposed=(Window,Worker)]
interface BroadcastChannel : EventTarget {
  constructor(DOMString name);

  readonly attribute DOMString name;
  undefined postMessage(any message);
  undefined close();
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};
```

For web developers (non-normative)

***broadcastChannel* = new BroadcastChannel[p1148](*name*)**

Returns a new BroadcastChannel[p1147] object via which messages for the given channel name can be sent and received.

***broadcastChannel*.name**[p1148]

Returns the channel name (as passed to the constructor).

***broadcastChannel*.postMessage**[p1148]**(*message*)**

Sends the given message to other `BroadcastChannel`[p1147] objects set up for this channel. Messages can be structured objects, e.g. nested objects and arrays.

***broadcastChannel*.close**[p1149]**()**

Closes the `BroadcastChannel`[p1147] object, opening it up to garbage collection.

A `BroadcastChannel`[p1147] object has a **channel name** and a **closed flag**.

The **`new BroadcastChannel(name)`** constructor steps are:

1. Set this's channel name[p1148] to *name*.
2. Set this's closed flag[p1148] to false.

The **`name`** getter steps are to return this's channel name[p1148].

A `BroadcastChannel`[p1147] object is said to be **eligible for messaging** when its relevant global object[p1039] is either:

- a `Window`[p892] object whose associated `Document`[p894] is fully active[p966], or
- a `WorkerGlobalScope`[p1166] object whose closing[p1169] flag is false and whose worker[p1174] is not a suspendable worker[p1170].

The **`postMessage(message)`** method steps are:

1. If this is not eligible for messaging[p1148], then return.
2. If this's closed flag[p1148] is true, then throw an `"InvalidStateError"` `DOMException`.
3. Let *serialized* be StructuredSerialize[p120](*message*). Rethrow any exceptions.
4. Let *sourceOrigin* be this's relevant settings object[p1039]'s origin[p1032].
5. Let *sourceStorageKey* be the result of running obtain a storage key for non-storage purposes with this's relevant settings object[p1039].
6. Let *destinations* be a list of `BroadcastChannel`[p1147] objects that match the following criteria:
   - They are eligible for messaging[p1148].
   - The result of running obtain a storage key for non-storage purposes with their relevant settings object[p1039] equals *sourceStorageKey*.
   - Their channel name[p1148] is this's channel name[p1148].
7. Remove *source* from *destinations*.
8. Sort *destinations* such that all `BroadcastChannel`[p1147] objects whose relevant agents[p1029] are the same are sorted in creation order, oldest first. (This does not define a complete ordering. Within this constraint, user agents may sort the list in any implementation-defined manner.)
9. For each *destination* in *destinations*, queue a global task[p1073] on the DOM manipulation task source[p1080] given *destination*'s relevant global object[p1039] to perform the following steps:
   1. If *destination*'s closed flag[p1148] is true, then abort these steps.
   2. Let *targetRealm* be *destination*'s relevant realm[p1039].
   3. Let *data* be StructuredDeserialize[p120](*serialized*, *targetRealm*).

      If this throws an exception, catch it, fire an event named `messageerror`[p1407] at *destination*, using `MessageEvent`[p1128], with the `origin`[p1129] attribute initialized to the serialization[p869] of *sourceOrigin*, and then abort these steps.

4. Fire an event named `message`[p1407] at *destination*, using `MessageEvent`[p1128], with the `data`[p1128] attribute initialized to *data* and the `origin`[p1129] attribute initialized to the serialization[p869] of *sourceOrigin*.

While a `BroadcastChannel`[p1147] object whose closed flag[p1148] is false has an event listener registered for `message`[p1407] or `messageerror`[p1407] events, there must be a strong reference from the `BroadcastChannel`[p1147] object's relevant global object[p1039] to the `BroadcastChannel`[p1147] object itself.

The **`close()`** method steps are to set this's closed flag[p1148] to true.

Note

Authors are strongly encouraged to explicitly close `BroadcastChannel`[p1147] objects when they are no longer needed, so that they can be garbage collected. Creating many `BroadcastChannel`[p1147] objects and discarding them while leaving them with an event listener and without closing them can lead to an apparent memory leak, since the objects will continue to live for as long as they have an event listener (or until their page or worker is closed).

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported, as event handler IDL attributes[p1084], by all objects implementing the `BroadcastChannel`[p1147] interface:

Event handler[p1083]	Event handler event type[p1085]
`onmessage`	`message`[p1407]
`onmessageerror`	`messageerror`[p1407]

Example

Suppose a page wants to know when the user logs out, even when the user does so from another tab at the same site:

```
var authChannel = new BroadcastChannel('auth');
authChannel.onmessage = function (event) {
  if (event.data == 'logout')
    showLogout();
}

function logoutRequested() {
  // called when the user asks us to log them out
  doLogout();
  showLogout();
  authChannel.postMessage('logout');
}

function doLogout() {
  // actually log the user out (e.g. clearing cookies)
  // ...
}

function showLogout() {
  // update the UI to indicate we're logged out
  // ...
}
```

10 Web workers §p1150

10.1 Introduction §p1150

10.1.1 Scope §p1150

This section is non-normative.

This specification defines an API for running scripts in the background independently of any user interface scripts.

This allows for long-running scripts that are not interrupted by scripts that respond to clicks or other user interactions, and allows long tasks to be executed without yielding to keep the page responsive.

Workers (as these background scripts are called herein) are relatively heavy-weight, and are not intended to be used in large numbers. For example, it would be inappropriate to launch one worker for each pixel of a four megapixel image. The examples below show some appropriate uses of workers.

Generally, workers are expected to be long-lived, have a high start-up performance cost, and a high per-instance memory cost.

10.1.2 Examples §p1150

This section is non-normative.

There are a variety of uses that workers can be put to. The following subsections show various examples of this use.

10.1.2.1 A background number-crunching worker §p1150

This section is non-normative.

The simplest use of workers is for performing a computationally expensive task without interrupting the user interface.

In this example, the main document spawns a worker to (naïvely) compute prime numbers, and progressively displays the most recently found prime number.

The main page is as follows:

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <meta charset="utf-8">
  <title>Worker example: One-core computation</title>
 </head>
 <body>
  <p>The highest prime number discovered so far is: <output id="result"></output></p>
  <script>
   var worker = new Worker('worker.js');
   worker.onmessage = function (event) {
     document.getElementById('result').textContent = event.data;
   };
  </script>
 </body>
</html>
```

The `Worker()` p1175 constructor call creates a worker and returns a `Worker` p1174 object representing that worker, which is used to

communicate with the worker. That object's onmessage[p1175] event handler allows the code to receive messages from the worker.

The worker itself is as follows:

```
var n = 1;
search: while (true) {
  n += 1;
  for (var i = 2; i <= Math.sqrt(n); i += 1)
    if (n % i == 0)
     continue search;
  // found a prime!
  postMessage(n);
}
```

The bulk of this code is simply an unoptimized search for a prime number. The postMessage()[p1168] method is used to send a message back to the page when a prime is found.

View this example online.

10.1.2.2 Using a JavaScript module as a worker §[p1151]

This section is non-normative.

All of our examples so far show workers that run classic scripts[p1040]. Workers can instead be instantiated using module scripts[p1040], which have the usual benefits: the ability to use the JavaScript `import` statement to import other modules; strict mode by default; and top-level declarations not polluting the worker's global scope.

As the `import` statement is available, the importScripts()[p1178] method will automatically fail inside module workers.

In this example, the main document uses a worker to do off-main-thread image manipulation. It imports the filters used from another module.

The main page is as follows:

```
<!DOCTYPE html>
<html lang="en">
<meta charset="utf-8">
<title>Worker example: image decoding</title>

<p>
  <label>
    Type an image URL to decode
    <input type="url" id="image-url" list="image-list">
    <datalist id="image-list">
      <option value="https://html.spec.whatwg.org/images/drawImage.png">
      <option value="https://html.spec.whatwg.org/images/robots.jpeg">
      <option value="https://html.spec.whatwg.org/images/arcTo2.png">
    </datalist>
  </label>
</p>

<p>
  <label>
    Choose a filter to apply
    <select id="filter">
      <option value="none">none</option>
      <option value="grayscale">grayscale</option>
      <option value="brighten">brighten by 20%</option>
    </select>
  </label>
</p>
```

```
<div id="output"></div>

<script type="module">
  const worker = new Worker("worker.js", { type: "module" });
  worker.onmessage = receiveFromWorker;

  const url = document.querySelector("#image-url");
  const filter = document.querySelector("#filter");
  const output = document.querySelector("#output");

  url.oninput = updateImage;
  filter.oninput = sendToWorker;

  let imageData, context;

  function updateImage() {
    const img = new Image();
    img.src = url.value;

    img.onload = () => {
      const canvas = document.createElement("canvas");
      canvas.width = img.width;
      canvas.height = img.height;

      context = canvas.getContext("2d");
      context.drawImage(img, 0, 0);
      imageData = context.getImageData(0, 0, canvas.width, canvas.height);

      sendToWorker();
      output.replaceChildren(canvas);
    };
  }

  function sendToWorker() {
    worker.postMessage({ imageData, filter: filter.value });
  }

  function receiveFromWorker(e) {
    context.putImageData(e.data, 0, 0);
  }
</script>
```

The worker file is then:

```
import * as filters from "./filters.js";

self.onmessage = e => {
  const { imageData, filter } = e.data;
  filters[filter](imageData);
  self.postMessage(imageData, [imageData.data.buffer]);
};
```

Which imports the file `filters.js`:

```
export function none() {}

export function grayscale({ data: d }) {
  for (let i = 0; i < d.length; i += 4) {
    const [r, g, b] = [d[i], d[i + 1], d[i + 2]];
```

```
    // CIE luminance for the RGB
    // The human eye is bad at seeing red and blue, so we de-emphasize them.
    d[i] = d[i + 1] = d[i + 2] = 0.2126 * r + 0.7152 * g + 0.0722 * b;
  }
};

export function brighten({ data: d }) {
  for (let i = 0; i < d.length; ++i) {
    d[i] *= 1.2;
  }
};
```

View this example online.

10.1.2.3 Shared workers introduction §[p11 53]

This section is non-normative.

This section introduces shared workers using a Hello World example. Shared workers use slightly different APIs, since each worker can have multiple connections.

This first example shows how you connect to a worker and how a worker can send a message back to the page when it connects to it. Received messages are displayed in a log.

Here is the HTML page:

```
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 1</title>
<pre id="log">Log:</pre>
<script>
  var worker = new SharedWorker('test.js');
  var log = document.getElementById('log');
  worker.port.onmessage = function(e) { // note: not worker.onmessage!
    log.textContent += '\n' + e.data;
  }
</script>
```

Here is the JavaScript worker:

```
onconnect = function(e) {
  var port = e.ports[0];
  port.postMessage('Hello World!');
}
```

View this example online.

This second example extends the first one by changing two things: first, messages are received using `addEventListener()` instead of an event handler IDL attribute[p1084], and second, a message is sent *to* the worker, causing the worker to send another message in return. Received messages are again displayed in a log.

Here is the HTML page:

```
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 2</title>
<pre id="log">Log:</pre>
```

```
<script>
  var worker = new SharedWorker('test.js');
  var log = document.getElementById('log');
  worker.port.addEventListener('message', function(e) {
    log.textContent += '\n' + e.data;
  }, false);
  worker.port.start(); // note: need this when using addEventListener
  worker.port.postMessage('ping');
</script>
```

Here is the JavaScript worker:

```
onconnect = function(e) {
  var port = e.ports[0];
  port.postMessage('Hello World!');
  port.onmessage = function(e) {
    port.postMessage('pong'); // not e.ports[0].postMessage!
    // e.target.postMessage('pong'); would work also
  }
}
```

View this example online.

Finally, the example is extended to show how two pages can connect to the same worker; in this case, the second page is merely in an iframe[p383] on the first page, but the same principle would apply to an entirely separate page in a separate top-level traversable[p953].

Here is the outer HTML page:

```
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 3</title>
<pre id="log">Log:</pre>
<script>
  var worker = new SharedWorker('test.js');
  var log = document.getElementById('log');
  worker.port.addEventListener('message', function(e) {
    log.textContent += '\n' + e.data;
  }, false);
  worker.port.start();
  worker.port.postMessage('ping');
</script>
<iframe src="inner.html"></iframe>
```

Here is the inner HTML page:

```
<!DOCTYPE HTML>
<html lang="en">
<meta charset="utf-8">
<title>Shared workers: demo 3 inner frame</title>
<pre id=log>Inner log:</pre>
<script>
  var worker = new SharedWorker('test.js');
  var log = document.getElementById('log');
  worker.port.onmessage = function(e) {
   log.textContent += '\n' + e.data;
  }
</script>
```

Here is the JavaScript worker:

```
var count = 0;
onconnect = function(e) {
  count += 1;
  var port = e.ports[0];
  port.postMessage('Hello World! You are connection #' + count);
  port.onmessage = function(e) {
    port.postMessage('pong');
  }
}
```

View this example online.

10.1.2.4 Shared state using a shared worker §p11 55

This section is non-normative.

In this example, multiple windows (viewers) can be opened that are all viewing the same map. All the windows share the same map information, with a single worker coordinating all the viewers. Each viewer can move around independently, but if they set any data on the map, all the viewers are updated.

The main page isn't interesting, it merely provides a way to open the viewers:

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <meta charset="utf-8">
  <title>Workers example: Multiviewer</title>
  <script>
   function openViewer() {
     window.open('viewer.html');
   }
  </script>
 </head>
 <body>
  <p><button type=button onclick="openViewer()">Open a new
  viewer</button></p>
  <p>Each viewer opens in a new window. You can have as many viewers
  as you like, they all view the same data.</p>
 </body>
</html>
```

The viewer is more involved:

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <meta charset="utf-8">
  <title>Workers example: Multiviewer viewer</title>
  <script>
   var worker = new SharedWorker('worker.js', 'core');

   // CONFIGURATION
   function configure(event) {
     if (event.data.substr(0, 4) != 'cfg ') return;
     var name = event.data.substr(4).split(' ', 1)[0];
     // update display to mention our name is name
     document.getElementsByTagName('h1')[0].textContent += ' ' + name;
     // no longer need this listener
     worker.port.removeEventListener('message', configure, false);
   }
```

```
  worker.port.addEventListener('message', configure, false);

  // MAP
  function paintMap(event) {
    if (event.data.substr(0, 4) != 'map ') return;
    var data = event.data.substr(4).split(',');
    // display tiles data[0] .. data[8]
    var canvas = document.getElementById('map');
    var context = canvas.getContext('2d');
    for (var y = 0; y < 3; y += 1) {
      for (var x = 0; x < 3; x += 1) {
        var tile = data[y * 3 + x];
        if (tile == '0')
          context.fillStyle = 'green';
        else
          context.fillStyle = 'maroon';
        context.fillRect(x * 50, y * 50, 50, 50);
      }
    }
  }
  worker.port.addEventListener('message', paintMap, false);

  // PUBLIC CHAT
  function updatePublicChat(event) {
    if (event.data.substr(0, 4) != 'txt ') return;
    var name = event.data.substr(4).split(' ', 1)[0];
    var message = event.data.substr(4 + name.length + 1);
    // display "<name> message" in public chat
    var public = document.getElementById('public');
    var p = document.createElement('p');
    var n = document.createElement('button');
    n.textContent = '<' + name + '> ';
    n.onclick = function () { worker.port.postMessage('msg ' + name); };
    p.appendChild(n);
    var m = document.createElement('span');
    m.textContent = message;
    p.appendChild(m);
    public.appendChild(p);
  }
  worker.port.addEventListener('message', updatePublicChat, false);

  // PRIVATE CHAT
  function startPrivateChat(event) {
    if (event.data.substr(0, 4) != 'msg ') return;
    var name = event.data.substr(4).split(' ', 1)[0];
    var port = event.ports[0];
    // display a private chat UI
    var ul = document.getElementById('private');
    var li = document.createElement('li');
    var h3 = document.createElement('h3');
    h3.textContent = 'Private chat with ' + name;
    li.appendChild(h3);
    var div = document.createElement('div');
    var addMessage = function(name, message) {
      var p = document.createElement('p');
      var n = document.createElement('strong');
      n.textContent = '<' + name + '> ';
      p.appendChild(n);
      var t = document.createElement('span');
      t.textContent = message;
      p.appendChild(t);
      div.appendChild(p);
```

```
      };
      port.onmessage = function (event) {
        addMessage(name, event.data);
      };
      li.appendChild(div);
      var form = document.createElement('form');
      var p = document.createElement('p');
      var input = document.createElement('input');
      input.size = 50;
      p.appendChild(input);
      p.appendChild(document.createTextNode(' '));
      var button = document.createElement('button');
      button.textContent = 'Post';
      p.appendChild(button);
      form.onsubmit = function () {
        port.postMessage(input.value);
        addMessage('me', input.value);
        input.value = '';
        return false;
      };
      form.appendChild(p);
      li.appendChild(form);
      ul.appendChild(li);
    }
    worker.port.addEventListener('message', startPrivateChat, false);

    worker.port.start();
   </script>
  </head>
  <body>
   <h1>Viewer</h1>
   <h2>Map</h2>
   <p><canvas id="map" height=150 width=150></canvas></p>
   <p>
    <button type=button onclick="worker.port.postMessage('mov left')">Left</button>
    <button type=button onclick="worker.port.postMessage('mov up')">Up</button>
    <button type=button onclick="worker.port.postMessage('mov down')">Down</button>
    <button type=button onclick="worker.port.postMessage('mov right')">Right</button>
    <button type=button onclick="worker.port.postMessage('set 0')">Set 0</button>
    <button type=button onclick="worker.port.postMessage('set 1')">Set 1</button>
   </p>
   <h2>Public Chat</h2>
   <div id="public"></div>
   <form onsubmit="worker.port.postMessage('txt ' + message.value); message.value = ''; return false;">
    <p>
     <input type="text" name="message" size="50">
     <button>Post</button>
    </p>
   </form>
   <h2>Private Chat</h2>
   <ul id="private"></ul>
  </body>
 </html>
```

There are several key things worth noting about the way the viewer is written.

Multiple listeners. Instead of a single message processing function, the code here attaches multiple event listeners, each one performing a quick check to see if it is relevant for the message. In this example it doesn't make much difference, but if multiple authors wanted to collaborate using a single port to communicate with a worker, it would allow for independent code instead of changes having to all be made to a single event handling function.

Registering event listeners in this way also allows you to unregister specific listeners when you are done with them, as is done with the `configure()` method in this example.

Finally, the worker:

```
var nextName = 0;
function getNextName() {
  // this could use more friendly names
  // but for now just return a number
  return nextName++;
}

var map = [
 [0, 0, 0, 0, 0, 0, 0],
 [1, 1, 0, 1, 0, 1, 1],
 [0, 1, 0, 1, 0, 0, 0],
 [0, 1, 0, 1, 0, 1, 1],
 [0, 0, 0, 1, 0, 0, 0],
 [1, 0, 0, 1, 1, 1, 1],
 [1, 1, 0, 1, 1, 0, 1],
];

function wrapX(x) {
  if (x < 0) return wrapX(x + map[0].length);
  if (x >= map[0].length) return wrapX(x - map[0].length);
  return x;
}

function wrapY(y) {
  if (y < 0) return wrapY(y + map.length);
  if (y >= map[0].length) return wrapY(y - map.length);
  return y;
}

function wrap(val, min, max) {
  if (val < min)
    return val + (max-min)+1;
  if (val > max)
    return val - (max-min)-1;
  return val;
}

function sendMapData(viewer) {
  var data = '';
  for (var y = viewer.y-1; y <= viewer.y+1; y += 1) {
    for (var x = viewer.x-1; x <= viewer.x+1; x += 1) {
      if (data != '')
        data += ',';
      data += map[wrap(y, 0, map[0].length-1)][wrap(x, 0, map.length-1)];
    }
  }
  viewer.port.postMessage('map ' + data);
}

var viewers = {};
onconnect = function (event) {
  var name = getNextName();
  event.ports[0]._data = { port: event.ports[0], name: name, x: 0, y: 0, };
  viewers[name] = event.ports[0]._data;
  event.ports[0].postMessage('cfg ' + name);
  event.ports[0].onmessage = getMessage;
  sendMapData(event.ports[0]._data);
};

function getMessage(event) {
```

```
  switch (event.data.substr(0, 4)) {
    case 'mov ':
      var direction = event.data.substr(4);
      var dx = 0;
      var dy = 0;
      switch (direction) {
        case 'up': dy = -1; break;
        case 'down': dy = 1; break;
        case 'left': dx = -1; break;
        case 'right': dx = 1; break;
      }
      event.target._data.x = wrapX(event.target._data.x + dx);
      event.target._data.y = wrapY(event.target._data.y + dy);
      sendMapData(event.target._data);
      break;
    case 'set ':
      var value = event.data.substr(4);
      map[event.target._data.y][event.target._data.x] = value;
      for (var viewer in viewers)
        sendMapData(viewers[viewer]);
      break;
    case 'txt ':
      var name = event.target._data.name;
      var message = event.data.substr(4);
      for (var viewer in viewers)
        viewers[viewer].port.postMessage('txt ' + name + ' ' + message);
      break;
    case 'msg ':
      var party1 = event.target._data;
      var party2 = viewers[event.data.substr(4).split(' ', 1)[0]];
      if (party2) {
        var channel = new MessageChannel();
        party1.port.postMessage('msg ' + party2.name, [channel.port1]);
        party2.port.postMessage('msg ' + party1.name, [channel.port2]);
      }
      break;
  }
}
```

Connecting to multiple pages. The script uses the onconnect[p1169] event listener to listen for multiple connections.

Direct channels. When the worker receives a "msg" message from one viewer naming another viewer, it sets up a direct connection between the two, so that the two viewers can communicate directly without the worker having to proxy all the messages.

View this example online.

10.1.2.5 Delegation §[p1159]

This section is non-normative.

With multicore CPUs becoming prevalent, one way to obtain better performance is to split computationally expensive tasks amongst multiple workers. In this example, a computationally expensive task that is to be performed for every number from 1 to 10,000,000 is farmed out to ten subworkers.

The main page is as follows, it just reports the result:

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <meta charset="utf-8">
  <title>Worker example: Multicore computation</title>
```

```
 </head>
 <body>
  <p>Result: <output id="result"></output></p>
  <script>
   var worker = new Worker('worker.js');
   worker.onmessage = function (event) {
     document.getElementById('result').textContent = event.data;
   };
  </script>
 </body>
</html>
```

The worker itself is as follows:

```
// settings
var num_workers = 10;
var items_per_worker = 1000000;

// start the workers
var result = 0;
var pending_workers = num_workers;
for (var i = 0; i < num_workers; i += 1) {
  var worker = new Worker('core.js');
  worker.postMessage(i * items_per_worker);
  worker.postMessage((i+1) * items_per_worker);
  worker.onmessage = storeResult;
}

// handle the results
function storeResult(event) {
  result += 1*event.data;
  pending_workers -= 1;
  if (pending_workers <= 0)
    postMessage(result); // finished!
}
```

It consists of a loop to start the subworkers, and then a handler that waits for all the subworkers to respond.

The subworkers are implemented as follows:

```
var start;
onmessage = getStart;
function getStart(event) {
  start = 1*event.data;
  onmessage = getEnd;
}

var end;
function getEnd(event) {
  end = 1*event.data;
  onmessage = null;
  work();
}

function work() {
  var result = 0;
  for (var i = start; i < end; i += 1) {
    // perform some complex calculation here
    result += 1;
  }
  postMessage(result);
  close();
```

```
}
```

They receive two numbers in two events, perform the computation for the range of numbers thus specified, and then report the result back to the parent.

View this example online.

10.1.2.6 Providing libraries §p11 61

This section is non-normative.

Suppose that a cryptography library is made available that provides three tasks:

Generate a public/private key pair

Takes a port, on which it will send two messages, first the public key and then the private key.

Given a plaintext and a public key, return the corresponding ciphertext

Takes a port, to which any number of messages can be sent, the first giving the public key, and the remainder giving the plaintext, each of which is encrypted and then sent on that same channel as the ciphertext. The user can close the port when it is done encrypting content.

Given a ciphertext and a private key, return the corresponding plaintext

Takes a port, to which any number of messages can be sent, the first giving the private key, and the remainder giving the ciphertext, each of which is decrypted and then sent on that same channel as the plaintext. The user can close the port when it is done decrypting content.

The library itself is as follows:

```
function handleMessage(e) {
  if (e.data == "genkeys")
    genkeys(e.ports[0]);
  else if (e.data == "encrypt")
    encrypt(e.ports[0]);
  else if (e.data == "decrypt")
    decrypt(e.ports[0]);
}

function genkeys(p) {
  var keys = _generateKeyPair();
  p.postMessage(keys[0]);
  p.postMessage(keys[1]);
}

function encrypt(p) {
  var key, state = 0;
  p.onmessage = function (e) {
    if (state == 0) {
      key = e.data;
      state = 1;
    } else {
      p.postMessage(_encrypt(key, e.data));
    }
  };
}

function decrypt(p) {
  var key, state = 0;
  p.onmessage = function (e) {
    if (state == 0) {
      key = e.data;
      state = 1;
```

```
    } else {
      p.postMessage(_decrypt(key, e.data));
    }
  };
}

// support being used as a shared worker as well as a dedicated worker
if ('onmessage' in this) // dedicated worker
  onmessage = handleMessage;
else // shared worker
  onconnect = function (e) { e.port.onmessage = handleMessage; }

// the "crypto" functions:

function _generateKeyPair() {
  return [Math.random(), Math.random()];
}

function _encrypt(k, s) {
  return 'encrypted-' + k + ' ' + s;
}

function _decrypt(k, s) {
  return s.substr(s.indexOf(' ')+1);
}
```

Note that the crypto functions here are just stubs and don't do real cryptography.

This library could be used as follows:

```
<!DOCTYPE HTML>
<html lang="en">
 <head>
  <meta charset="utf-8">
  <title>Worker example: Crypto library</title>
  <script>
   const cryptoLib = new Worker('libcrypto-v1.js'); // or could use 'libcrypto-v2.js'
   function startConversation(source, message) {
     const messageChannel = new MessageChannel();
     source.postMessage(message, [messageChannel.port2]);
     return messageChannel.port1;
   }
   function getKeys() {
     let state = 0;
     startConversation(cryptoLib, "genkeys").onmessage = function (e) {
       if (state === 0)
         document.getElementById('public').value = e.data;
       else if (state === 1)
         document.getElementById('private').value = e.data;
       state += 1;
     };
   }
   function enc() {
     const port = startConversation(cryptoLib, "encrypt");
     port.postMessage(document.getElementById('public').value);
     port.postMessage(document.getElementById('input').value);
     port.onmessage = function (e) {
       document.getElementById('input').value = e.data;
       port.close();
     };
   }
```

```
    function dec() {
      const port = startConversation(cryptoLib, "decrypt");
      port.postMessage(document.getElementById('private').value);
      port.postMessage(document.getElementById('input').value);
      port.onmessage = function (e) {
        document.getElementById('input').value = e.data;
        port.close();
      };
    }
  </script>
  <style>
   textarea { display: block; }
  </style>
 </head>
 <body onload="getKeys()">
  <fieldset>
   <legend>Keys</legend>
   <p><label>Public Key: <textarea id="public"></textarea></label></p>
   <p><label>Private Key: <textarea id="private"></textarea></label></p>
  </fieldset>
  <p><label>Input: <textarea id="input"></textarea></label></p>
  <p><button onclick="enc()">Encrypt</button> <button onclick="dec()">Decrypt</button></p>
 </body>
</html>
```

A later version of the API, though, might want to offload all the crypto work onto subworkers. This could be done as follows:

```
function handleMessage(e) {
  if (e.data == "genkeys")
    genkeys(e.ports[0]);
  else if (e.data == "encrypt")
    encrypt(e.ports[0]);
  else if (e.data == "decrypt")
    decrypt(e.ports[0]);
}

function genkeys(p) {
  var generator = new Worker('libcrypto-v2-generator.js');
  generator.postMessage('', [p]);
}

function encrypt(p) {
  p.onmessage = function (e) {
    var key = e.data;
    var encryptor = new Worker('libcrypto-v2-encryptor.js');
    encryptor.postMessage(key, [p]);
  };
}

function encrypt(p) {
  p.onmessage = function (e) {
    var key = e.data;
    var decryptor = new Worker('libcrypto-v2-decryptor.js');
    decryptor.postMessage(key, [p]);
  };
}

// support being used as a shared worker as well as a dedicated worker
if ('onmessage' in this) // dedicated worker
  onmessage = handleMessage;
else // shared worker
  onconnect = function (e) { e.ports[0].onmessage = handleMessage };
```

The little subworkers would then be as follows.

For generating key pairs:

```
onmessage = function (e) {
  var k = _generateKeyPair();
  e.ports[0].postMessage(k[0]);
  e.ports[0].postMessage(k[1]);
  close();
}

function _generateKeyPair() {
  return [Math.random(), Math.random()];
}
```

For encrypting:

```
onmessage = function (e) {
  var key = e.data;
  e.ports[0].onmessage = function (e) {
    var s = e.data;
    postMessage(_encrypt(key, s));
  }
}

function _encrypt(k, s) {
  return 'encrypted-' + k + ' ' + s;
}
```

For decrypting:

```
onmessage = function (e) {
  var key = e.data;
  e.ports[0].onmessage = function (e) {
    var s = e.data;
    postMessage(_decrypt(key, s));
  }
}

function _decrypt(k, s) {
  return s.substr(s.indexOf(' ')+1);
}
```

Notice how the users of the API don't have to even know that this is happening — the API hasn't changed; the library can delegate to subworkers without changing its API, even though it is accepting data using message channels.

View this example online.

10.1.3 Tutorials §p11 64

10.1.3.1 Creating a dedicated worker §p11 64

This section is non-normative.

Creating a worker requires a URL to a JavaScript file. The `Worker()`p1175 constructor is invoked with the URL to that file as its only argument; a worker is then created and returned:

```
var worker = new Worker('helper.js');
```

If you want your worker script to be interpreted as a module scriptp1040 instead of the default classic scriptp1040, you need to use a

slightly different signature:

```
var worker = new Worker('helper.mjs', { type: "module" });
```

10.1.3.2 Communicating with a dedicated worker §[p1165]

This section is non-normative.

Dedicated workers use MessagePort[p1144] objects behind the scenes, and thus support all the same features, such as sending structured data, transferring binary data, and transferring other ports.

To receive messages from a dedicated worker, use the onmessage[p1175] event handler IDL attribute[p1084] on the Worker[p1174] object:

```
worker.onmessage = function (event) { ... };
```

You can also use the addEventListener() method.

Note

The implicit MessagePort[p1144] used by dedicated workers has its port message queue[p1144] implicitly enabled when it is created, so there is no equivalent to the MessagePort[p1144] interface's start()[p1146] method on the Worker[p1174] interface.

To *send* data to a worker, use the postMessage()[p1175] method. Structured data can be sent over this communication channel. To send ArrayBuffer objects efficiently (by transferring them rather than cloning them), list them in an array in the second argument.

```
worker.postMessage({
  operation: 'find-edges',
  input: buffer, // an ArrayBuffer object
  threshold: 0.6,
}, [buffer]);
```

To receive a message inside the worker, the onmessage[p1168] event handler IDL attribute[p1084] is used.

```
onmessage = function (event) { ... };
```

You can again also use the addEventListener() method.

In either case, the data is provided in the event object's data[p1128] attribute.

To send messages back, you again use postMessage()[p1168]. It supports the structured data in the same manner.

```
postMessage(event.data.input, [event.data.input]); // transfer the buffer back
```

✔ MDN

10.1.3.3 Shared workers §[p1165]

This section is non-normative.

Shared workers are identified by the URL of the script used to create it, optionally with an explicit name. The name allows multiple instances of a particular shared worker to be started.

Shared workers are scoped by origin[p869]. Two different sites using the same names will not collide. However, if a page tries to use the same shared worker name as another page on the same site, but with a different script URL, it will fail.

Creating shared workers is done using the SharedWorker()[p1176] constructor. This constructor takes the URL to the script to use for its first argument, and the name of the worker, if any, as the second argument.

```
var worker = new SharedWorker('service.js');
```

Communicating with shared workers is done with explicit MessagePort[p1144] objects. The object returned by the SharedWorker()[p1176] constructor holds a reference to the port on its port[p1176] attribute.

```
worker.port.onmessage = function (event) { ... };
worker.port.postMessage('some message');
worker.port.postMessage({ foo: 'structured', bar: ['data', 'also', 'possible']});
```

Inside the shared worker, new clients of the worker are announced using the connect[p1406] event. The port for the new client is given by the event object's source[p1129] attribute.

```
onconnect = function (event) {
  var newPort = event.source;
  // set up a listener
  newPort.onmessage = function (event) { ... };
  // send a message back to the port
  newPort.postMessage('ready!'); // can also send structured data, of course
};
```

10.2 Infrastructure §[p1166]

This standard defines two kinds of workers: dedicated workers, and shared workers. Dedicated workers, once created, are linked to their creator, but message ports can be used to communicate from a dedicated worker to multiple other browsing contexts or workers. Shared workers, on the other hand, are named, and once created any script running in the same origin[p869] can obtain a reference to that worker and communicate with it. *Service Workers* defines a third kind. [SW][p1417]

10.2.1 The global scope §[p1166]

The global scope is the "inside" of a worker.

10.2.1.1 The WorkerGlobalScope[p1166] common interface §[p1166]

IDL

```
[Exposed=Worker]
interface WorkerGlobalScope : EventTarget {
  readonly attribute WorkerGlobalScope self;
  readonly attribute WorkerLocation location;
  readonly attribute WorkerNavigator navigator;
  undefined importScripts(USVString... urls);

  attribute OnErrorEventHandler onerror;
  attribute EventHandler onlanguagechange;
  attribute EventHandler onoffline;
  attribute EventHandler ononline;
  attribute EventHandler onrejectionhandled;
  attribute EventHandler onunhandledrejection;
};
```

WorkerGlobalScope[p1166] serves as the base class for specific types of worker global scope objects, including DedicatedWorkerGlobalScope[p1168], SharedWorkerGlobalScope[p1168], and ServiceWorkerGlobalScope.

A WorkerGlobalScope[p1166] object has an associated **owner set** (a set of Document[p127] and WorkerGlobalScope[p1166] objects). It is initially empty and populated when the worker is created or obtained.

Note

It is a set, instead of a single owner, to accommodate SharedWorkerGlobalScope[p1168] objects.

A WorkerGlobalScope[p1166] object has an associated **type** ("classic" or "module"). It is set during creation.

A WorkerGlobalScope[p1166] object has an associated **url** (null or a URL). It is initially null.

A WorkerGlobalScope[p1166] object has an associated **name** (a string). It is set during creation.

Note

The name[p1167] can have different semantics for each subclass of WorkerGlobalScope[p1166]. For DedicatedWorkerGlobalScope[p1168] instances, it is simply a developer-supplied name, useful mostly for debugging purposes. For SharedWorkerGlobalScope[p1168] instances, it allows obtaining a reference to a common shared worker via the SharedWorker()[p1176] constructor. For ServiceWorkerGlobalScope objects, it doesn't make sense (and as such isn't exposed through the JavaScript API at all).

A WorkerGlobalScope[p1166] object has an associated **policy container** (a policy container[p888]). It is initially a new policy container[p888].

A WorkerGlobalScope[p1166] object has an associated **embedder policy** (an embedder policy[p883]).

A WorkerGlobalScope[p1166] object has an associated **module map**. It is a module map[p1068], initially empty.

A WorkerGlobalScope[p1166] object has an associated **cross-origin isolated capability** boolean. It is initially false.

For web developers (non-normative)

***workerGlobal*.self**[p1167]

Returns *workerGlobal*.

***workerGlobal*.location**[p1167]

Returns *workerGlobal*'s WorkerLocation[p1179] object.

***workerGlobal*.navigator**[p1179]

Returns *workerGlobal*'s WorkerNavigator[p1179] object.

***workerGlobal*.importScripts**[p1178]**(...*urls*)**

Fetches each URL in *urls*, executes them one-by-one in the order they are passed, and then returns (or throws if something went amiss).

The **self** attribute must return the WorkerGlobalScope[p1166] object itself.

The **location** attribute must return the WorkerLocation[p1179] object whose associated WorkerGlobalScope object[p1179] is the WorkerGlobalScope[p1166] object.

Note

While the WorkerLocation[p1179] object is created after the WorkerGlobalScope[p1166] object, this is not problematic as it cannot be observed from script.

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported, as event handler IDL attributes[p1084], by objects implementing the WorkerGlobalScope[p1166] interface:

Event handler[p1083]	Event handler event type[p1085]
onerror	error[p1406]
onlanguagechange	languagechange[p1407]
onoffline	offline[p1407]
ononline	online[p1407]
onrejectionhandled	rejectionhandled[p1407]
onunhandledrejection	unhandledrejection[p1407]

MDN
MDN
MDN
MDN

10.2.1.2 Dedicated workers and the DedicatedWorkerGlobalScope[p1168] interface §[p1167]

MDN

IDL
```
[Global=(Worker,DedicatedWorker),Exposed=DedicatedWorker]
```

```
interface DedicatedWorkerGlobalScope : WorkerGlobalScope {
  [Replaceable] readonly attribute DOMString name;

  undefined postMessage(any message, sequence<object> transfer);
  undefined postMessage(any message, optional StructuredSerializeOptions options = {});

  undefined close();

  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};
```

DedicatedWorkerGlobalScope[p1168] objects act as if they had an implicit MessagePort[p1144] associated with them. This port is part of a channel that is set up when the worker is created, but it is not exposed. This object must never be garbage collected before the DedicatedWorkerGlobalScope[p1168] object.

All messages received by that port must immediately be retargeted at the DedicatedWorkerGlobalScope[p1168] object.

For web developers (non-normative)

***dedicatedWorkerGlobal*.name**[p1168]

Returns *dedicatedWorkerGlobal*'s name[p1167], i.e. the value given to the Worker[p1174] constructor. Primarily useful for debugging.

***dedicatedWorkerGlobal*.postMessage**[p1168]**(*message* [, *transfer*])**

***dedicatedWorkerGlobal*.postMessage**[p1168]**(*message* [, { transfer**[p1144]** }])**

Clones *message* and transmits it to the Worker[p1174] object associated with *dedicatedWorkerGlobal*. *transfer* can be passed as a list of objects that are to be transferred rather than cloned.

***dedicatedWorkerGlobal*.close**[p1168]**()**

Aborts *dedicatedWorkerGlobal*.

The **name** getter steps are to return this's name[p1167]. Its value represents the name given to the worker using the Worker[p1174] constructor, used primarily for debugging purposes.

The **postMessage(*message, transfer*)** and **postMessage(*message, options*)** methods on DedicatedWorkerGlobalScope[p1168] objects act as if, when invoked, it immediately invoked the respective postMessage(*message, transfer*)[p1146] and postMessage(*message, options*)[p1146] on the port, with the same arguments, and returned the same return value.

To **close a worker**, given a *workerGlobal*, run these steps:

1. Discard any tasks[p1071] that have been added to *workerGlobal*'s relevant agent[p1029]'s event loop[p1071]'s task queues[p1071].
2. Set *workerGlobal*'s closing[p1169] flag to true. (This prevents any further tasks from being queued.)

The **close()** method steps are to close a worker[p1168] given this.

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported, as event handler IDL attributes[p1084], by objects implementing the DedicatedWorkerGlobalScope[p1168] interface:

Event handler[p1083]	Event handler event type[p1085]
onmessage	message[p1407]
onmessageerror	messageerror[p1407]

✔ MDN
✔ MDN

✔ MDN

10.2.1.3 Shared workers and the SharedWorkerGlobalScope[p1168] interface §[p1168]

IDL
```
[Global=(Worker,SharedWorker),Exposed=SharedWorker]
interface SharedWorkerGlobalScope : WorkerGlobalScope {
  [Replaceable] readonly attribute DOMString name;
```

```
  undefined close();

  attribute EventHandler onconnect;
};
```

A SharedWorkerGlobalScope[p1168] object has an associated **constructor origin**, **constructor url**, and **credentials**. They are initialized when the SharedWorkerGlobalScope[p1168] object is created, in the run a worker[p1170] algorithm.

Shared workers receive message ports through connect[p1406] events on their SharedWorkerGlobalScope[p1168] object for each connection.

For web developers (non-normative)

***sharedWorkerGlobal*.name**[p1169]

Returns *sharedWorkerGlobal*'s name[p1167], i.e. the value given to the SharedWorker[p1176] constructor. Multiple SharedWorker[p1176] objects can correspond to the same shared worker (and SharedWorkerGlobalScope[p1168]), by reusing the same name.

***sharedWorkerGlobal*.close**[p1169]**()**

Aborts *sharedWorkerGlobal*.

The **name** getter steps are to return this's name[p1167]. Its value represents the name that can be used to obtain a reference to the worker using the SharedWorker[p1176] constructor.

The **close()** method steps are to close a worker[p1168] given this.

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported, as event handler IDL attributes[p1084], by objects implementing the SharedWorkerGlobalScope[p1168] interface:

Event handler[p1083]	Event handler event type[p1085]
onconnect	connect[p1406]

MDN

10.2.2 The event loop §[p1169]

A worker event loop[p1071]'s task queues[p1071] only have events, callbacks, and networking activity as tasks[p1071]. These worker event loops[p1071] are created by the run a worker[p1170] algorithm.

Each WorkerGlobalScope[p1166] object has a **closing** flag, which must be initially false, but which can get set to true by the algorithms in the processing model section below.

Once the WorkerGlobalScope[p1166]'s closing[p1169] flag is set to true, the event loop[p1071]'s task queues[p1071] must discard any further tasks[p1071] that would be added to them (tasks already on the queue are unaffected except where otherwise specified). Effectively, once the closing[p1169] flag is true, timers stop firing, notifications for all pending background operations are dropped, etc.

10.2.3 The worker's lifetime §[p1169]

Workers communicate with other workers and with Window[p892]s through message channels[p1141] and their MessagePort[p1144] objects.

Each WorkerGlobalScope[p1166] object *worker global scope* has a list of **the worker's ports**, which consists of all the MessagePort[p1144] objects that are entangled with another port and that have one (but only one) port owned by *worker global scope*. This list includes the implicit MessagePort[p1144] in the case of dedicated workers[p1168].

Given an environment settings object[p1032] *o* when creating or obtaining a worker, the **relevant owner to add** depends on the type of global object[p1033] specified by *o*. If *o*'s global object[p1033] is a WorkerGlobalScope[p1166] object (i.e., if we are creating a nested dedicated worker), then the relevant owner is that global object. Otherwise, *o*'s global object[p1033] is a Window[p892] object, and the relevant owner is that Window[p892]'s associated Document[p894].

A worker is said to be a **permissible worker** if its WorkerGlobalScope[p1166]'s owner set[p1166] is not empty or:

- its owner set[p1166] has been empty for no more than a short implementation-defined timeout value,
- its WorkerGlobalScope[p1166] object is a SharedWorkerGlobalScope[p1168] object (i.e., the worker is a shared worker), and
- the user agent has a navigable[p952] whose active document[p952] is not completely loaded[p1021].

Note

The second part of this definition allows a shared worker to survive for a short time while a page is loading, in case that page is going to contact the shared worker again. This can be used by user agents as a way to avoid the cost of restarting a shared worker used by a site when the user is navigating from page to page within that site.

A worker is said to be an **active needed worker** if any its owners[p1166] are either Document[p127] objects that are fully active[p966] or active needed workers[p1170].

A worker is said to be a **protected worker** if it is an active needed worker[p1170] and either it has outstanding timers, database transactions, or network connections, or its list of the worker's ports[p1169] is not empty, or its WorkerGlobalScope[p1166] is actually a SharedWorkerGlobalScope[p1168] object (i.e., the worker is a shared worker).

A worker is said to be a **suspendable worker** if it is not an active needed worker[p1170] but it is a permissible worker[p1170].

10.2.4 Processing model §[p1170]

When a user agent is to **run a worker** for a script with Worker[p1174] or SharedWorker[p1176] object *worker*, URL *url*, environment settings object[p1032] *outside settings*, MessagePort[p1144] *outside port*, and a WorkerOptions[p1174] dictionary *options*, it must run the following steps.

1. Let *is shared* be true if *worker* is a SharedWorker[p1176] object, and false otherwise.
2. Let *owner* be the relevant owner to add[p1169] given *outside settings*.
3. Let *parent worker global scope* be null.
4. If *owner* is a WorkerGlobalScope[p1166] object (i.e., we are creating a nested dedicated worker), then set *parent worker global scope* to *owner*.
5. Let *unsafeWorkerCreationTime* be the unsafe shared current time.
6. Let *agent* be the result of obtaining a dedicated/shared worker agent[p1030] given *outside settings* and *is shared*. Run the rest of these steps in that agent.
7. Let *realm execution context* be the result of creating a new realm[p1033] given *agent* and the following customizations:
    - For the global object, if *is shared* is true, create a new SharedWorkerGlobalScope[p1168] object. Otherwise, create a new DedicatedWorkerGlobalScope[p1168] object.
8. Let *worker global scope* be the global object[p1033] of *realm execution context*'s Realm component.

    Note

    This is the DedicatedWorkerGlobalScope[p1168] *or* SharedWorkerGlobalScope[p1168] *object created in the previous step.*

9. Set up a worker environment settings object[p1173] with *realm execution context*, *outside settings*, and *unsafeWorkerCreationTime*, and let *inside settings* be the result.
10. Set *worker global scope*'s name[p1167] to the value of *options*'s `name` member.
11. Append *owner* to *worker global scope*'s owner set[p1166].
12. If *is shared* is true, then:
    1. Set *worker global scope*'s constructor origin[p1169] to *outside settings*'s origin[p1032].
    2. Set *worker global scope*'s constructor url[p1169] to *url*.
    3. Set *worker global scope*'s type[p1167] to the value of *options*'s `type` member.

4. Set *worker global scope*'s credentials[p1169] to the value of *options*'s `credentials` member.

13. Let *destination* be "`sharedworker`" if *is shared* is true, and "`worker`" otherwise.

14. Obtain *script* by switching on the value of *options*'s `type` member:

    ↪ **"`classic`"**

    Fetch a classic worker script[p1043] given *url*, *outside settings*, *destination*, *inside settings*, and with *onComplete* and *performFetch* as defined below.

    ↪ **"`module`"**

    Fetch a module worker script graph[p1045] given *url*, *outside settings*, *destination*, the value of the `credentials` member of *options*, *inside settings*, and with *onComplete* and *performFetch* as defined below.

    In both cases, let *performFetch* be the following perform the fetch hook[p1042] given *request*, *isTopLevel*[p1042] and *processCustomFetchResponse*[p1042]:

    1. If *isTopLevel* is false, fetch *request* with *processResponseConsumeBody* set to *processCustomFetchResponse*, and abort these steps.

    2. Set *request*'s reserved client to *inside settings*.

    3. Fetch *request* with *processResponseConsumeBody* set to the following steps given response *response* and null, failure, or a byte sequence *bodyBytes*:

        1. Set *worker global scope*'s url[p1167] to *response*'s url.

        2. Initialize worker global scope's policy container[p889] given *worker global scope*, *response*, and *inside settings*.

        3. If the Run CSP initialization for a global object algorithm returns "`Blocked`" when executed upon *worker global scope*, set *response* to a network error. [CSP][p1411]

        4. If *worker global scope*'s embedder policy[p1167]'s value[p883] is compatible with cross-origin isolation[p883] and *is shared* is true, then set *agent*'s agent cluster's cross-origin isolation mode[p1029] to "`logical`[p965]" or "`concrete`[p965]". The one chosen is implementation-defined.

            This really ought to be set when the agent cluster is created, which requires a redesign of this section.

        5. If the result of checking a global object's embedder policy[p884] with *worker global scope*, *outside settings*, and *response* is false, then set *response* to a network error.

        6. Set *worker global scope*'s cross-origin isolated capability[p1167] to true if *agent*'s agent cluster's cross-origin isolation mode[p1029] is "`concrete`[p965]".

        7. If *is shared* is false and *owner*'s cross-origin isolated capability[p1032] is false, then set *worker global scope*'s cross-origin isolated capability[p1167] to false.

        8. If *is shared* is false and *response*'s url's scheme is "`data`", then set *worker global scope*'s cross-origin isolated capability[p1167] to false.

            Note

            This is a conservative default for now, while we figure out how workers in general, and `data:` URL workers in particular (which are cross-origin from their owner), will be treated in the context of permissions policies. See w3c/webappsec-permissions-policy issue #207 for more details.

        9. Run *processCustomFetchResponse* with *response* and *bodyBytes*.

    In both cases, let *onComplete* given *script* be the following steps:

    1. If *script* is null or if *script*'s error to rethrow[p1040] is non-null, then:

        1. Queue a global task[p1073] on the DOM manipulation task source[p1080] given *worker*'s relevant global object[p1039] to fire an event named `error`[p1406] at *worker*.

        2. Run the environment discarding steps[p1032] for *inside settings*.

3. Abort these steps.

2. Associate *worker* with *worker global scope*.

3. Let *inside port* be a new `MessagePort`[p1144] object in *inside settings*'s realm[p1033].

4. Associate *inside port* with *worker global scope*.

5. Entangle[p1145] *outside port* and *inside port*.

6. Create a new `WorkerLocation`[p1179] object and associate it with *worker global scope*.

7. **Closing orphan workers**: Start monitoring the worker such that no sooner than it stops being a protected worker[p1170], and no later than it stops being a permissible worker[p1170], *worker global scope*'s closing[p1169] flag is set to true.

8. **Suspending workers**: Start monitoring the worker, such that whenever *worker global scope*'s closing[p1169] flag is false and the worker is a suspendable worker[p1170], the user agent suspends execution of script in that worker until such time as either the closing[p1169] flag switches to true or the worker stops being a suspendable worker[p1170].

9. Set *inside settings*'s execution ready flag[p1032].

10. If *script* is a classic script[p1040], then run the classic script[p1050] *script*. Otherwise, it is a module script[p1040]; run the module script[p1051] *script*.

    Note

    In addition to the usual possibilities of returning a value or failing due to an exception, this could be prematurely aborted[p1052] by the terminate a worker[p1172] algorithm defined below.

11. Enable *outside port*'s port message queue[p1144].

12. If *is shared* is false, enable the port message queue[p1144] of the worker's implicit port.

13. If *is shared* is true, then queue a global task[p1073] on DOM manipulation task source[p1080] given *worker global scope* to fire an event named `connect`[p1406] at *worker global scope*, using `MessageEvent`[p1128], with the `data`[p1128] attribute initialized to the empty string, the `ports`[p1129] attribute initialized to a new frozen array containing *inside port*, and the `source`[p1129] attribute initialized to *inside port*.

14. Enable the client message queue of the `ServiceWorkerContainer` object whose associated service worker client is *worker global scope*'s relevant settings object[p1039].

15. **Event loop**: Run the responsible event loop[p1032] specified by *inside settings* until it is destroyed.

    Note

    The handling of events or the execution of callbacks by tasks[p1071] run by the event loop[p1071] might get prematurely aborted[p1052] by the terminate a worker[p1172] algorithm defined below.

    Note

    The worker processing model remains on this step until the event loop is destroyed, which happens after the closing[p1169] flag is set to true, as described in the event loop[p1071] processing model.

16. Clear the *worker global scope*'s map of active timers[p1101].

17. Disentangle all the ports in the list of the worker's ports[p1169].

18. Empty *worker global scope*'s owner set[p1166].

When a user agent is to **terminate a worker** it must run the following steps in parallel[p43] with the worker's main loop (the "run a worker[p1170]" processing model defined above):

1. Set the worker's `WorkerGlobalScope`[p1166] object's closing[p1169] flag to true.

2. If there are any tasks[p1071] queued in the `WorkerGlobalScope`[p1166] object's relevant agent[p1029]'s event loop[p1071]'s task queues[p1071], discard them without processing them.

3. Abort the script[p1052] currently running in the worker.

4. If the worker's WorkerGlobalScope[p1166] object is actually a DedicatedWorkerGlobalScope[p1168] object (i.e. the worker is a dedicated worker), then empty the port message queue[p1144] of the port that the worker's implicit port is entangled with.

User agents may invoke the terminate a worker[p1172] algorithm when a worker stops being an active needed worker[p1170] and the worker continues executing even after its closing[p1169] flag was set to true.

10.2.5 Runtime script errors §[p1173]

Whenever an uncaught runtime script error occurs in one of the worker's scripts, if the error did not occur while handling a previous script error, the user agent must report the error[p1053] for that script[p1040], with the position (line number and column number) where the error occurred, using the WorkerGlobalScope[p1166] object as the target.

For shared workers, if the error is still *not handled*[p1053] afterwards, the error may be reported to a developer console.

For dedicated workers, if the error is still *not handled*[p1053] afterwards, the user agent must queue a task[p1072] to run these steps:

1. Let *notHandled* be the result of firing an event named error[p1406] at the Worker[p1174] object associated with the worker, using ErrorEvent[p1054], with the cancelable attribute initialized to true, the message[p1054], filename[p1054], lineno[p1054], and colno[p1054] attributes initialized appropriately, and the error[p1054] attribute initialized to null.

2. If *notHandled* is true, then the user agent must act as if the uncaught runtime script error had occurred in the global scope that the Worker[p1174] object is in, thus repeating the entire runtime script error reporting process one level up.

If the implicit port connecting the worker to its Worker[p1174] object has been disentangled (i.e. if the parent worker has been terminated), then the user agent must act as if the Worker[p1174] object had no error[p1406] event handler and as if that worker's onerror[p1167] attribute was null, but must otherwise act as described above.

Note

Thus, error reports propagate up to the chain of dedicated workers up to the original Document[p127], even if some of the workers along this chain have been terminated and garbage collected.

The task source[p1072] for the task mentioned above is the DOM manipulation task source[p1080].

10.2.6 Creating workers §[p1173]

10.2.6.1 The AbstractWorker[p1173] mixin §[p1173]

```
IDL
interface mixin AbstractWorker {
  attribute EventHandler onerror;
};
```

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported, as event handler IDL attributes[p1084], by objects implementing the AbstractWorker[p1173] interface:

Event handler[p1083]	Event handler event type[p1085]
onerror	error[p1406]

10.2.6.2 Script settings for workers §[p1173]

To **set up a worker environment settings object**, given a JavaScript execution context *execution context*, an environment settings object[p1032] *outside settings*, and a number *unsafeWorkerCreationTime*:

1. Let *inherited origin* be *outside settings*'s origin[p1032].

2. Let *realm* be the value of *execution context*'s Realm component.

3. Let *worker global scope* be *realm*'s global object[p1033].

4. Let *settings object* be a new environment settings object[p1032] whose algorithms are defined as follows:

   The realm execution context[p1032]

   Return *execution context*.

   The module map[p1032]

   Return *worker global scope*'s module map[p1167].

   The API URL character encoding[p1032]

   Return UTF-8.

   The API base URL[p1032]

   Return *worker global scope*'s url[p1167].

   The origin[p1032]

   Return a unique opaque origin[p869] if *worker global scope*'s url[p1167]'s scheme is "`data`", and *inherited origin* otherwise.

   The policy container[p1032]

   Return *worker global scope*'s policy container[p1167].

   The cross-origin isolated capability[p1032]

   Return *worker global scope*'s cross-origin isolated capability[p1167].

   The time origin[p1032]

   Return the result of coarsening *unsafeWorkerCreationTime* with *worker global scope*'s cross-origin isolated capability[p1167].

5. Set *settings object*'s id[p1031] to a new unique opaque string, creation URL[p1031] to *worker global scope*'s url, top-level creation URL[p1031] to null, target browsing context[p1032] to null, and active service worker[p1032] to null.

6. If *worker global scope* is a `DedicatedWorkerGlobalScope`[p1168] object, then set *settings object*'s top-level origin[p1031] to *outside settings*'s top-level origin[p1031].

7. Otherwise, set *settings object*'s top-level origin[p1031] to an implementation-defined value.

   See Client-Side Storage Partitioning for the latest on properly defining this.

8. Set *realm*'s [[HostDefined]] field to *settings object*.

9. Return *settings object*.

10.2.6.3 Dedicated workers and the `Worker`[p1174] interface §[p1174]

IDL

```
[Exposed=(Window,DedicatedWorker,SharedWorker)]
interface Worker : EventTarget {
  constructor(USVString scriptURL, optional WorkerOptions options = {});

  undefined terminate();

  undefined postMessage(any message, sequence<object> transfer);
  undefined postMessage(any message, optional StructuredSerializeOptions options = {});
  attribute EventHandler onmessage;
  attribute EventHandler onmessageerror;
};

dictionary WorkerOptions {
  WorkerType type = "classic";
  RequestCredentials credentials = "same-origin"; // credentials is only used if type is "module"
  DOMString name = "";
};
```

```
enum WorkerType { "classic", "module" };

Worker includes AbstractWorker;
```

For web developers (non-normative)

***worker* = new Worker[p1175](*scriptURL* [, *options*])**

Returns a new Worker[p1174] object. *scriptURL* will be fetched and executed in the background, creating a new global environment for which *worker* represents the communication channel. *options* can be used to define the name[p1167] of that global environment via the `name` option, primarily for debugging purposes. It can also ensure this new global environment supports JavaScript modules (specify `type: "module"`), and if that is specified, can also be used to specify how *scriptURL* is fetched through the `credentials` option.

***worker*.terminate[p1175]()**

Aborts *worker*'s associated global environment.

***worker*.postMessage[p1175](*message* [, *transfer*])**

***worker*.postMessage[p1175](*message* [, { transfer[p1144] }])**

Clones *message* and transmits it to *worker*'s global environment. *transfer* can be passed as a list of objects that are to be transferred rather than cloned.

The **terminate()** method, when invoked, must cause the terminate a worker[p1172] algorithm to be run on the worker with which the object is associated.

Worker[p1174] objects act as if they had an implicit MessagePort[p1144] associated with them. This port is part of a channel that is set up when the worker is created, but it is not exposed. This object must never be garbage collected before the Worker[p1174] object.

All messages received by that port must immediately be retargeted at the Worker[p1174] object.

The **postMessage(*message, transfer*)** and **postMessage(*message, options*)** methods on Worker[p1174] objects act as if, when invoked, they immediately invoked the respective postMessage(*message, transfer*)[p1146] and postMessage(*message, options*)[p1146] on the port, with the same arguments, and returned the same return value.

Example

The postMessage()[p1175] method's first argument can be structured data:

```
worker.postMessage({opcode: 'activate', device: 1938, parameters: [23, 102]});
```

The following are the event handlers[p1083] (and their corresponding event handler event types[p1085]) that must be supported, as event handler IDL attributes[p1084], by objects implementing the Worker[p1174] interface:

Event handler[p1083]	Event handler event type[p1085]
onmessage	message[p1407]
onmessageerror	messageerror[p1407]

When the **Worker(*scriptURL, options*)** constructor is invoked, the user agent must run the following steps:

1. The user agent may throw a "SecurityError" DOMException if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start dedicated workers).
2. Let *outside settings* be the current settings object[p1038].
3. Parse[p95] the *scriptURL* argument relative to *outside settings*.
4. If this fails, throw a "SyntaxError" DOMException.
5. Let *worker URL* be the resulting URL record[p95].

Note

Any same-origin[p870] URL (including blob: URLs) can be used. data: URLs can also be used, but they create a worker with an opaque origin[p869].

6. Let *worker* be a new Worker[p1174] object.
7. Let *outside port* be a new MessagePort[p1144] in *outside settings*'s realm[p1033].
8. Associate the *outside port* with *worker*.
9. Run this step in parallel[p43]:
    1. Run a worker[p1170] given *worker*, *worker URL*, *outside settings*, *outside port*, and *options*.
10. Return *worker*.

10.2.6.4 Shared workers and the SharedWorker[p1176] interface §[p1176]

```
IDL
[Exposed=Window]
interface SharedWorker : EventTarget {
  constructor(USVString scriptURL, optional (DOMString or WorkerOptions) options = {});

  readonly attribute MessagePort port;
};
SharedWorker includes AbstractWorker;
```

For web developers (non-normative)

***sharedWorker* = new SharedWorker[p1176](*scriptURL* [, *name*])**

Returns a new SharedWorker[p1176] object. *scriptURL* will be fetched and executed in the background, creating a new global environment for which *sharedWorker* represents the communication channel. *name* can be used to define the name[p1167] of that global environment.

***sharedWorker* = new SharedWorker[p1176](*scriptURL* [, *options*])**

Returns a new SharedWorker[p1176] object. *scriptURL* will be fetched and executed in the background, creating a new global environment for which *sharedWorker* represents the communication channel. *options* can be used to define the name[p1167] of that global environment via the `name` option. It can also ensure this new global environment supports JavaScript modules (specify `type: "module"`), and if that is specified, can also be used to specify how *scriptURL* is fetched through the `credentials` option. Note that attempting to construct a shared worker with *options* whose `type` or `credentials` values mismatch an existing shared worker will cause the returned *sharedWorker* to fire an error event and not connect to the existing shared worker.

***sharedWorker*.port[p1176]**

Returns *sharedWorker*'s MessagePort[p1144] object which can be used to communicate with the global environment.

The **port** attribute must return the value it was assigned by the object's constructor. It represents the MessagePort[p1144] for communicating with the shared worker.

A user agent has an associated **shared worker manager** which is the result of starting a new parallel queue[p43].

Note

Each user agent has a single shared worker manager[p1176] for simplicity. Implementations could use one per origin[p869]; that would not be observably different and enables more concurrency.

When the **SharedWorker(*scriptURL, options*)** constructor is invoked:

1. Optionally, throw a "SecurityError" DOMException if the request violates a policy decision (e.g. if the user agent is configured to not allow the page to start shared workers).
2. If *options* is a DOMString, set *options* to a new WorkerOptions[p1174] dictionary whose `name` member is set to the value of *options* and whose other members are set to their default values.
3. Let *outside settings* be the current settings object[p1038].
4. Parse[p95] *scriptURL* relative to *outside settings*.
5. If this fails, throw a "SyntaxError" DOMException.

6. Otherwise, let *urlRecord* be the resulting URL record[p95].

> **Note**
> *Any same-origin[p870] URL (including `blob:` URLs) can be used. `data:` URLs can also be used, but they create a worker with an opaque origin[p869].*

7. Let *worker* be a new `SharedWorker`[p1176] object.
8. Let *outside port* be a new `MessagePort`[p1144] in *outside settings*'s realm[p1033].
9. Assign *outside port* to the `port`[p1176] attribute of *worker*.
10. Let *callerIsSecureContext* be true if *outside settings* is a secure context[p1039]; otherwise, false.
11. Let *outside storage key* be the result of running obtain a storage key for non-storage purposes given *outside settings*.
12. Enqueue the following steps[p43] to the shared worker manager[p1176]:
    1. Let *worker global scope* be null.
    2. For each *scope* in the list of all `SharedWorkerGlobalScope`[p1168] objects:
       1. Let *worker storage key* be the result of running obtain a storage key for non-storage purposes given *scope*'s relevant settings object[p1039].
       2. If all of the following conditions are true:
          - *worker storage key* equals *outside storage key*;
          - *scope*'s closing[p1169] flag is false;
          - *scope*'s constructor url[p1169] equals *urlRecord*; and
          - *scope*'s name[p1167] equals the value of *option*'s `name` member

          then:
          1. Set *worker global scope* to *scope*.
          2. Break.

       > **Note**
       > *`data:` URLs create a worker with an opaque origin[p869]. Both the constructor origin[p1169] and constructor url[p1169] are compared so the same `data:` URL can be used within an origin[p869] to get to the same `SharedWorkerGlobalScope`[p1168] object, but cannot be used to bypass the same origin[p870] restriction.*

    3. If *worker global scope* is not null, but the user agent has been configured to disallow communication between the worker represented by the *worker global scope* and the scripts[p1040] whose settings object[p1040] is *outside settings*, then set *worker global scope* to null.

       > **Note**
       > *For example, a user agent could have a development mode that isolates a particular top-level traversable[p953] from all other pages, and scripts in that development mode could be blocked from connecting to shared workers running in the normal browser mode.*

    4. If *worker global scope* is not null, then check if *worker global scope*'s type[p1167] and credentials[p1169] match the *options* values. If not, queue a task[p1072] to fire an event named `error`[p1406] and abort these steps.
    5. If *worker global scope* is not null, then run these subsubsteps:
       1. Let *settings object* be the relevant settings object[p1039] for *worker global scope*.
       2. Let *workerIsSecureContext* be true if *settings object* is a secure context[p1039]; otherwise, false.
       3. If *workerIsSecureContext* is not *callerIsSecureContext*, then queue a task[p1072] to fire an event named `error`[p1406] at *worker* and abort these steps. [SECURE-CONTEXTS][p1417]
       4. Associate *worker* with *worker global scope*.
       5. Let *inside port* be a new `MessagePort`[p1144] in *settings object*'s realm[p1033].
       6. Entangle[p1145] *outside port* and *inside port*.

7. Queue a task[p1072], using the DOM manipulation task source[p1080], to fire an event named `connect`[p1406] at *worker global scope*, using `MessageEvent`[p1128], with the `data`[p1128] attribute initialized to the empty string, the `ports`[p1129] attribute initialized to a new frozen array containing only *inside port*, and the `source`[p1129] attribute initialized to *inside port*.

8. Append the relevant owner to add[p1169] given *outside settings* to *worker global scope*'s owner set[p1166].

6. Otherwise, in parallel[p43], run a worker[p1170] given *worker*, *urlRecord*, *outside settings*, *outside port*, and *options*.

13. Return *worker*.

10.2.7 Concurrent hardware capabilities §[p1178]

```
IDL
interface mixin NavigatorConcurrentHardware {
  readonly attribute unsigned long long hardwareConcurrency;
};
```

For web developers (non-normative)

***self*.navigator**[p1109]**.hardwareConcurrency**[p1178]

Returns the number of logical processors potentially available to the user agent.

The **`navigator.hardwareConcurrency`** attribute's getter must return a number between 1 and the number of logical processors potentially available to the user agent. If this cannot be determined, the getter must return 1.

User agents should err toward exposing the number of logical processors available, using lower values only in cases where there are user-agent specific limits in place (such as a limitation on the number of workers[p1174] that can be created) or when the user agent desires to limit fingerprinting possibilities.

10.3 APIs available to workers §[p1178]

10.3.1 Importing scripts and libraries §[p1178]

The **`importScripts(...urls)`** method steps are to import scripts into worker global scope[p1178] given this and *urls*.

To **import scripts into worker global scope**, given a `WorkerGlobalScope`[p1166] object *worker global scope*, a list of scalar value strings *urls*, and an optional perform the fetch hook[p1042] *performFetch*:

1. If *worker global scope*'s type[p1167] is "`module`", throw a `TypeError` exception.

2. Let *settings object* be the current settings object[p1038].

3. If *urls* is empty, return.

4. Parse[p95] each value in *urls* relative to *settings object*. If any fail, throw a `"SyntaxError"` `DOMException`.

5. For each *url* in the resulting URL records[p95]:

    1. Fetch a classic worker-imported script[p1044] given *url* and *settings object*, passing along *performFetch* if provided. If this succeeds, let *script* be the result. Otherwise, rethrow the exception.

    2. Run the classic script[p1050] *script*, with the rethrow errors argument set to true.

    Note

    script *will run until it either returns, fails to parse, fails to catch an exception, or gets prematurely aborted*[p1052] *by the terminate a worker*[p1172] *algorithm defined above.*

    If an exception was thrown or if the script was prematurely aborted[p1052], then abort all these steps, letting the exception or aborting continue to be processed by the calling script[p1040].

Note

Service Workers *is an example of a specification that runs this algorithm with its own perform the fetch hook*[p1042]. *[SW]*[p1417]

10.3.2 The WorkerNavigator[p1179] interface §[p1179]

The **navigator** attribute of the WorkerGlobalScope[p1166] interface must return an instance of the WorkerNavigator[p1179] interface, which represents the identity and state of the user agent (the client):

IDL
```
[Exposed=Worker]
interface WorkerNavigator {};
WorkerNavigator includes NavigatorID;
WorkerNavigator includes NavigatorLanguage;
WorkerNavigator includes NavigatorOnLine;
WorkerNavigator includes NavigatorConcurrentHardware;
```

10.3.3 The WorkerLocation[p1179] interface §[p1179]

IDL
```
[Exposed=Worker]
interface WorkerLocation {
  stringifier readonly attribute USVString href;
  readonly attribute USVString origin;
  readonly attribute USVString protocol;
  readonly attribute USVString host;
  readonly attribute USVString hostname;
  readonly attribute USVString port;
  readonly attribute USVString pathname;
  readonly attribute USVString search;
  readonly attribute USVString hash;
};
```

A WorkerLocation[p1179] object has an associated **WorkerGlobalScope object** (a WorkerGlobalScope[p1166] object).

The **href** getter steps are to return this's WorkerGlobalScope object[p1179]'s url[p1167], serialized.

The **origin** getter steps are to return the serialization[p869] of this's WorkerGlobalScope object[p1179]'s url[p1167]'s origin.

The **protocol** getter steps are to return this's WorkerGlobalScope object[p1179]'s url[p1167]'s scheme, followed by ":".

The **host** getter steps are:

1. Let *url* be this's WorkerGlobalScope object[p1179]'s url[p1167].
2. If *url*'s host is null, return the empty string.
3. If *url*'s port is null, return *url*'s host, serialized.
4. Return *url*'s host, serialized, followed by ":" and *url*'s port, serialized.

The **hostname** getter steps are:

1. Let *host* be this's WorkerGlobalScope object[p1179]'s url[p1167]'s host.
2. If *host* is null, return the empty string.
3. Return *host*, serialized.

The **port** getter steps are:

1. Let *port* be this's WorkerGlobalScope object[p1179]'s url[p1167]'s port.

2. If *port* is null, return the empty string.
3. Return *port*, serialized.

The **pathname** getter steps are to return the result of URL path serializing this's `WorkerGlobalScope` object[p1179]'s url[p1167].

The **search** getter steps are:

1. Let *query* be this's `WorkerGlobalScope` object[p1179]'s url[p1167]'s query.
2. If *query* is either null or the empty string, return the empty string.
3. Return "?", followed by *query*.

The **hash** getter steps are:

1. Let *fragment* be this's `WorkerGlobalScope` object[p1179]'s url[p1167]'s fragment.
2. If *fragment* is either null or the empty string, return the empty string.
3. Return "#", followed by *fragment*.

11 Worklets §p11 81

11.1 Introduction §p11 81

This section is non-normative.

Worklets are a piece of specification infrastructure which can be used for running scripts independent of the main JavaScript execution environment, while not requiring any particular implementation model.

The worklet infrastructure specified here cannot be used directly by web developers. Instead, other specifications build upon it to create directly-usable worklet types, specialized for running in particular parts of the browser implementation pipeline.

11.1.1 Motivations §p11 81

This section is non-normative.

Allowing extension points to rendering, or other sensitive parts of the implementation pipeline such as audio output, is difficult. If extension points were done with full access to the APIs available on `Window`p892, engines would need to abandon previously-held assumptions for what could happen in the middle of those phases. For example, during the layout phase, rendering engines assume that no DOM will be modified.

Additionally, defining extension points in the `Window`p892 environment would restrict user agents to performing work in the same thread as the `Window`p892 object. (Unless implementations added complex, high-overhead infrastructure to allow thread-safe APIs, as well as thread-joining guarantees.)

Worklets are designed to allow extension points, while keeping guarantees that user agents currently rely on. This is done through new global environments, based on subclasses of `WorkletGlobalScope`p1184.

Worklets are similar to web workers. However, they:

- Are thread-agnostic. That is, they are not designed to run on a dedicated separate thread, like each worker is. Implementations can run worklets wherever they choose (including on the main thread).
- Are able to have multiple duplicate instances of the global scope created, for the purpose of parallelism.
- Do not use an event-based API. Instead, classes are registered on the global scope, whose methods are invoked by the user agent.
- Have a reduced API surface on the global scope.
- Have a lifetime for their global objectp1033 which is defined by other specifications, often in an implementation-defined manner.

As worklets have relatively high overhead, they are best used sparingly. Due to this, a given `WorkletGlobalScope`p1184 is expected to be shared between multiple separate scripts. (This is similar to how a single `Window`p892 is shared between multiple separate scripts.)

Worklets are a general technology that serve different use cases. Some worklets, such as those defined in *CSS Painting API*, provide extension points intended for stateless, idempotent, and short-running computations, which have special considerations as described in the next couple of sections. Others, such as those defined in *Web Audio API*, are used for stateful, long-running operations. [CSSPAINT]p1412 [WEBAUDIO]p1418

11.1.2 Code idempotence §p11 81

Some specifications which use worklets are intended to allow user agents to parallelize work over multiple threads, or to move work between threads as required. In these specifications, user agents might invoke methods on a web-developer-provided class in an implementation-defined order.

As a result of this, to prevent interoperability issues, authors who register classes on such `WorkletGlobalScope`p1184s should make their

code idempotent. That is, a method or set of methods on the class should produce the same output given a particular input.

This specification uses the following techniques in order to encourage authors to write code in an idempotent way:

- No reference to the global object is available (i.e., there is no counterpart to `self`[p1167] on `WorkletGlobalScope`[p1184]).

  Although this was the intention when worklets were first specified, the introduction of `globalThis` has made it no longer true. See issue #6059 for more discussion.

- Code is loaded as a module script[p1040], which results in the code being executed in strict mode and with no shared `this` referencing the global proxy.

Together, these restrictions help prevent two different scripts from sharing state using properties of the global object[p1033].

Additionally, specifications which use worklets and intend to allow implementation-defined behavior must obey the following:

- They must require user agents to always have at least two `WorkletGlobalScope`[p1184] instances per `Worklet`[p1187], and randomly assign a method or set of methods on a class to a particular `WorkletGlobalScope`[p1184] instance. These specifications may provide an opt-out under memory constraints.
- These specifications must allow user agents to create and destroy instances of their `WorkletGlobalScope`[p1184] subclasses at any time.

11.1.3 Speculative evaluation §[p1182]

Some specifications which use worklets can invoke methods on a web-developer-provided class based on the state of the user agent. To increase concurrency between threads, a user agent may invoke a method speculatively, based on potential future states.

In these specifications, user agents might invoke such methods at any time, and with any arguments, not just ones corresponding to the current state of the user agent. The results of such speculative evaluations are not displayed immediately, but can be cached for use if the user agent state matches the speculated state. This can increase the concurrency between the user agent and worklet threads.

As a result of this, to prevent interoperability risks between user agents, authors who register classes on such `WorkletGlobalScope`[p1184]s should make their code stateless. That is, the only effect of invoking a method should be its result, and not any side effects such as updating mutable state.

The same techniques which encourage code idempotence[p1181] also encourage authors to write stateless code.

11.2 Examples §[p1182]

This section is non-normative.

For these examples, we'll use a fake worklet. The `Window`[p892] object provides two `Worklet`[p1187] instances, which each run code in their own collection of `FakeWorkletGlobalScope`[p1183]s:

IDL
```
partial interface Window {
  [SameObject, SecureContext] readonly attribute Worklet fakeWorklet1;
  [SameObject, SecureContext] readonly attribute Worklet fakeWorklet2;
};
```

Each `Window`[p892] has two `Worklet`[p1187] instances, **fake worklet 1** and **fake worklet 2**. Both of these have their worklet global scope type[p1187] set to `FakeWorkletGlobalScope`[p1183], and their worklet destination type[p1187] set to "`fakeworklet`". User agents should create at least two `FakeWorkletGlobalScope`[p1183] instances per worklet.

Note

"`fakeworklet`" *is not actually a valid destination per* Fetch. *But this illustrates how real worklets would generally have their own worklet-type-specific destination. [FETCH]*[p1413]

The **fakeWorklet1** getter steps are to return this's fake worklet 1[p1182].

The **fakeWorklet2** getter steps are to return this's fake worklet 2[p1182].

IDL
```
[Global=(Worklet,FakeWorklet),
 Exposed=FakeWorklet,
 SecureContext]
interface FakeWorkletGlobalScope : WorkletGlobalScope {
  undefined registerFake(DOMString type, Function classConstructor);
};
```

Each FakeWorkletGlobalScope[p1183] has a **registered class constructors map**, which is an ordered map, initially empty.

The **registerFake(*type*, *classConstructor*)** method steps are to set this's registered class constructors map[p1183][*type*] to *classConstructor*.

11.2.1 Loading scripts §[p1183]

This section is non-normative.

To load scripts into fake worklet 1[p1182], a web developer would write:

```
window.fakeWorklet1.addModule('script1.mjs');
window.fakeWorklet1.addModule('script2.mjs');
```

Note that which script finishes fetching and runs first is dependent on network timing: it could be either `script1.mjs` or `script2.mjs`. This generally won't matter for well-written scripts intended to be loaded in worklets, if they follow the suggestions about preparing for speculative evaluation[p1182].

If a web developer wants to perform a task only after the scripts have successfully run and loaded into some worklets, they could write:

```
Promise.all([
    window.fakeWorklet1.addModule('script1.mjs'),
    window.fakeWorklet2.addModule('script2.mjs')
]).then(() => {
    // Do something which relies on those scripts being loaded.
});
```

Another important point about script-loading is that loaded scripts can be run in multiple WorkletGlobalScope[p1184]s per Worklet[p1187], as discussed in the section on code idempotence[p1181]. In particular, the specification above for fake worklet 1[p1182] and fake worklet 2[p1182] require this. So, consider a scenario such as the following:

```
// script.mjs
console.log("Hello from a FakeWorkletGlobalScope!");
```

```
// app.mjs
window.fakeWorklet1.addModule("script.mjs");
```

This could result in output such as the following from a user agent's console:

```
[fakeWorklet1#1] Hello from a FakeWorkletGlobalScope!
[fakeWorklet1#4] Hello from a FakeWorkletGlobalScope!
[fakeWorklet1#2] Hello from a FakeWorkletGlobalScope!
[fakeWorklet1#3] Hello from a FakeWorkletGlobalScope!
```

If the user agent at some point decided to kill and restart the third instance of FakeWorkletGlobalScope[p1183], the console would again print `[fakeWorklet1#3] Hello from a FakeWorkletGlobalScope!` when this occurs.

11.2.2 Registering a class and invoking its methods §[p1184]

This section is non-normative.

Let's say that one of the intended usages of our fake worklet by web developers is to allow them to customize the highly-complex process of boolean negation. They might register their customization as follows:

```
// script.mjs
registerFake('negation-processor', class {
  process(arg) {
    return !arg;
  }
});
```

```
// app.mjs
window.fakeWorklet1.addModule("script.mjs");
```

To make use of such registered classes, the specification for fake worklets could define a **find the opposite of true** algorithm, given a Worklet[p1187] *worklet*:

1. Optionally, create a worklet global scope[p1185] for *worklet*.
2. Let *workletGlobalScope* be one of *worklet*'s global scopes[p1187], chosen in an implementation-defined manner.
3. Let *classConstructor* be *workletGlobalScope*'s registered class constructors map[p1183]["negation-processor"].
4. Let *classInstance* be the result of constructing *classConstructor*, with no arguments.
5. Let *function* be Get(*classInstance*, "process"). Rethrow any exceptions.
6. Let *callback* be the result of converting *function* to a Web IDL Function instance.
7. Return the result of invoking *callback* with the arguments « true » and with *classInstance* as the callback this value.

Note

Another, perhaps better, specification architecture would be to extract the "process" property and convert it into a Function at registration time, as part of the registerFake()[p1183] method steps.

11.3 Infrastructure §[p1184]

11.3.1 The global scope §[p1184]

Subclasses of WorkletGlobalScope[p1184] are used to create global objects[p1033] wherein code loaded into a particular Worklet[p1187] can execute.

IDL

```
[Exposed=Worklet, SecureContext]
interface WorkletGlobalScope {};
```

Note

Other specifications are intended to subclass WorkletGlobalScope[p1184], adding APIs to register a class, as well as other APIs specific for their worklet type.

Each WorkletGlobalScope[p1184] has an associated **module map**. It is a module map[p1068], initially empty.

11.3.1.1 Agents and event loops §[p1185]

This section is non-normative.

Each `WorkletGlobalScope`[p1184] is contained in its own worklet agent[p1028], which has its corresponding event loop[p1071]. However, in practice, implementation of these agents and event loops is expected to be different from most others.

A worklet agent[p1028] exists for each `WorkletGlobalScope`[p1184] since, in theory, an implementation could use a separate thread for each `WorkletGlobalScope`[p1184] instance, and allowing this level of parallelism is best done using agents. However, because their [[CanBlock]] value is false, there is no requirement that agents and threads are one-to-one. This allows implementations the freedom to execute scripts loaded into a worklet on any thread, including one running code from other agents with [[CanBlock]] of false, such as the thread of a similar-origin window agent[p1028] ("the main thread"). Contrast this with dedicated worker agents[p1028], whose true value for [[CanBlock]] effectively requires them to get a dedicated operating system thread.

Worklet event loops[p1071] are also somewhat special. They are only used for tasks[p1071] associated with `addModule()`[p1188], tasks wherein the user agent invokes author-defined methods, and microtasks[p1072]. Thus, even though the event loop processing model[p1074] specifies that all event loops run continuously, implementations can achieve observably-equivalent results using a simpler strategy, which just invokes author-provided methods and then relies on that process to perform a microtask checkpoint[p1077].

11.3.1.2 Creation and termination §[p1185]

To **create a worklet global scope** for a `Worklet`[p1187] *worklet*:

1. Let *outsideSettings* be *worklet*'s relevant settings object[p1039].
2. Let *agent* be the result of obtaining a worklet agent[p1030] given *outsideSettings*. Run the rest of these steps in that agent.
3. Let *realmExecutionContext* be the result of creating a new realm[p1033] given *agent* and the following customizations:
   - For the global object, create a new object of the type given by *worklet*'s worklet global scope type[p1187].
4. Let *workletGlobalScope* be the global object[p1033] of *realmExecutionContext*'s Realm component.
5. Let *insideSettings* be the result of setting up a worklet environment settings object[p1186] given *realmExecutionContext* and *outsideSettings*.
6. Let *pendingAddedModules* be a clone of *worklet*'s added modules list[p1187].
7. Let *runNextAddedModule* be the following steps:
   1. If *pendingAddedModules* is not empty, then:
      1. Let *moduleURL* be the result of dequeueing from *pendingAddedModules*.
      2. Fetch a worklet script graph[p1045] given *moduleURL*, *insideSettings*, *worklet*'s worklet destination type[p1187], what credentials mode?, *insideSettings*, *worklet*'s module responses map[p1187], and with the following steps given *script*:

         Note

         This will not actually perform a network request, as it will just reuse responses from worklet's *module responses map*[p1187]*. The main purpose of this step is to create a new* workletGlobalScope*-specific module script*[p1040] *from the response.*

         1. Assert: *script* is not null, since the fetch succeeded and the source text was successfully parsed when *worklet*'s module responses map[p1187] was initially populated with *moduleURL*.
         2. Run a module script[p1051] given *script*.
         3. Run *runNextAddedModule*.
      3. Abort these steps.
   2. Append *workletGlobalScope* to *outsideSettings*'s global object[p1033]'s associated `Document`[p894]'s worklet global scopes[p1189].
   3. Append *workletGlobalScope* to *worklet*'s global scopes[p1187].

4. Run the responsible event loop[p1032] specified by *insideSettings*.

8. Run *runNextAddedModule*.

To **terminate a worklet global scope** given a `WorkletGlobalScope`[p1184] *workletGlobalScope*:

1. Let *eventLoop* be *workletGlobalScope*'s relevant agent[p1029]'s event loop[p1071].
2. If there are any tasks[p1071] queued in *eventLoop*'s task queues[p1071], discard them without processing them.
3. Wait for *eventLoop* to complete the currently running task[p1072].
4. If the previous step doesn't complete within an implementation-defined period of time, then abort the script[p1052] currently running in the worklet.
5. Destroy *eventLoop*.
6. Remove *workletGlobalScope* from the global scopes[p1187] of the `Worklet`[p1187] whose global scopes[p1187] contains *workletGlobalScope*.
7. Remove *workletGlobalScope* from the worklet global scopes[p1189] of the `Document`[p127] whose worklet global scopes[p1189] contains *workletGlobalScope*.

11.3.1.3 Script settings for worklets §[p1186]

To **set up a worklet environment settings object**, given a JavaScript execution context *executionContext* and an environment settings object[p1032] *outsideSettings*:

1. Let *origin* be a unique opaque origin[p869].
2. Let *inheritedAPIBaseURL* be *outsideSettings*'s API base URL[p1032].
3. Let *inheritedPolicyContainer* be a clone[p888] of *outsideSettings*'s policy container[p1032].
4. Let *realm* be the value of *executionContext*'s Realm component.
5. Let *workletGlobalScope* be *realm*'s global object[p1033].
6. Let *settingsObject* be a new environment settings object[p1032] whose algorithms are defined as follows:

   The realm execution context[p1032]

   Return *executionContext*.

   The module map[p1032]

   Return *workletGlobalScope*'s module map[p1184].

   The API URL character encoding[p1032]

   Return UTF-8.

   The API base URL[p1032]

   Return *inheritedAPIBaseURL*.

   Note

   Unlike workers or other globals derived from a single resource, worklets have no primary resource; instead, multiple scripts, each with their own URL, are loaded into the global scope via `worklet.addModule()`[p1188]*. So this API base URL[p1032] is rather unlike that of other globals. However, so far this doesn't matter, as no APIs available to worklet code make use of the API base URL[p1032].*

   The origin[p1032]

   Return *origin*.

   The policy container[p1032]

   Return *inheritedPolicyContainer*.

The cross-origin isolated capability[p1032]

Return TODO.

The time origin[p1032]

Assert: this algorithm is never called, because the time origin[p1032] is not available in a worklet context.

7. Set *settingsObject*'s id[p1031] to a new unique opaque string, creation URL[p1031] to *inheritedAPIBaseURL*, top-level creation URL[p1031] to null, top-level origin[p1031] to *outsideSettings*'s top-level origin[p1031], target browsing context[p1032] to null, and active service worker[p1032] to null.

8. Set *realm*'s [[HostDefined]] field to *settingsObject*.

9. Return *settingsObject*.

11.3.2 The Worklet[p1187] class §[p1187]

The Worklet[p1187] class provides the capability to add module scripts into its associated WorkletGlobalScope[p1184]s. The user agent can then create classes registered on the WorkletGlobalScope[p1184]s and invoke their methods.

IDL
```
[Exposed=Window, SecureContext]
interface Worklet {
  [NewObject] Promise<undefined> addModule(USVString moduleURL, optional WorkletOptions options = {});
};

dictionary WorkletOptions {
  RequestCredentials credentials = "same-origin";
};
```

Specifications that create Worklet[p1187] instances must specify the following for a given instance:

- its **worklet global scope type**, which must be a Web IDL type that inherits from WorkletGlobalScope[p1184]; and
- its **worklet destination type**, which must be a destination, and is used when fetching scripts.

For web developers (non-normative)

`await worklet.addModule`[p1188]**`(moduleURL[, { credentials`**[p1187]**` }])`**

Loads and executes the module script[p1040] given by *moduleURL* into all of *worklet*'s global scopes[p1187]. It can also create additional global scopes as part of this process, depending on the worklet type. The returned promise will fulfill once the script has been successfully loaded and run in all global scopes.

The `credentials`[p1187] option can be set to a credentials mode to modify the script-fetching process. It defaults to "`same-origin`".

Any failures in fetching[p1045] the script or its dependencies will cause the returned promise to be rejected with an "`AbortError`" `DOMException`. Any errors in parsing the script or its dependencies will cause the returned promise to be rejected with the exception generated during parsing.

A Worklet[p1187] has a list of **global scopes**, which contains instances of the Worklet[p1187]'s worklet global scope type[p1187]. It is initially empty.

A Worklet[p1187] has an **added modules list**, which is a list of URLs, initially empty. Access to this list should be thread-safe.

A Worklet[p1187] has a **module responses map**, which is an ordered map from URLs to either "`fetching`" or tuples consisting of a response and either null, failure, or a byte sequence representing the response body. This map is initially empty, and access to it should be thread-safe.

Note

The added modules list[p1187] and module responses map[p1187] exist to ensure that WorkletGlobalScope[p1184]s created at different times get equivalent module scripts[p1040] run in them, based on the same source text. This allows the creation of additional WorkletGlobalScope[p1184]s to be transparent to the author.

In practice, user agents are not expected to implement these data structures, and the algorithms that consult them, using thread-safe programming techniques. Instead, when `addModule()`[p1188] is called, user agents can fetch the module graph on the main thread, and send the fetched source text (i.e., the important data contained in the module responses map[p1187]) to each thread which has a `WorkletGlobalScope`[p1184].

Then, when a user agent creates[p1185] a new `WorkletGlobalScope`[p1184] for a given `Worklet`[p1187], it can simply send the map of fetched source text and the list of entry points from the main thread to the thread containing the new `WorkletGlobalScope`[p1184].

The **`addModule(moduleURL, options)`** method steps are:

1. Let *outsideSettings* be the relevant settings object[p1039] of this.
2. Parse[p95] *moduleURL* relative to *outsideSettings*.
3. If this fails, then return a promise rejected with a `"SyntaxError"` `DOMException`.
4. Let *moduleURLRecord* be the resulting URL record[p95].
5. Let *promise* be a new promise.
6. Run the following steps in parallel[p43]:
    1. If this's global scopes[p1187] is empty, then:
        1. Create a worklet global scope[p1185] given this.
        2. Optionally, create[p1185] additional global scope instances given this, depending on the specific worklet in question and its specification.
        3. Wait for all steps of the creation[p1185] process(es) — including those taking place within the worklet agents[p1028] — to complete, before moving on.
    2. Let *pendingTasks* be this's global scopes[p1187]'s size.
    3. Let *addedSuccessfully* be false.
    4. For each *workletGlobalScope* of this's global scopes[p1187], queue a global task[p1073] on the networking task source[p1081] given *workletGlobalScope* to fetch a worklet script graph[p1045] given *moduleURLRecord*, *outsideSettings*, this's worklet destination type[p1187], *options*["`credentials`[p1187]"], *workletGlobalScope*'s relevant settings object[p1039], this's module responses map[p1187], and the following steps given *script*:

        Note

        Only the first of these fetches will actually perform a network request; the ones for other `WorkletGlobalScope`[p1184]s will reuse responses from this's module responses map[p1187].

        1. If *script* is null, then:
            1. Queue a global task[p1073] on the networking task source[p1081] given this's relevant global object[p1039] to perform the following steps:
                1. If *pendingTasks* is not −1, then:
                1. Set *pendingTasks* to −1.
                2. Reject *promise* with an `"AbortError"` `DOMException`.
            2. Abort these steps.
        2. If *script*'s error to rethrow[p1040] is not null, then:
            1. Queue a global task[p1073] on the networking task source[p1081] given this's relevant global object[p1039] to perform the following steps:
                1. If *pendingTasks* is not −1, then:
                1. Set *pendingTasks* to −1.

2. Reject *promise* with *script*'s error to rethrow[p1040].

2. Abort these steps.

3. If *addedSuccessfully* is false, then:

1. Append *moduleURLRecord* to this's added modules list[p1187].

2. Set *addedSuccessfully* to true.

4. Run a module script[p1051] given *script*.

5. Queue a global task[p1073] on the networking task source[p1081] given this's relevant global object[p1039] to perform the following steps:

1. If *pendingTasks* is not −1, then:

1. Set *pendingTasks* to *pendingTasks* − 1.

2. If *pendingTasks* is 0, then resolve *promise*.

7. Return *promise*.

11.3.3 The worklet's lifetime §[p1189]

The lifetime of a `Worklet`[p1187] has no special considerations; it is tied to the object it belongs to, such as the `Window`[p892].

Each `Document`[p127] has a **worklet global scopes**, which is a set of `WorkletGlobalScope`[p1184]s, initially empty.

The lifetime of a `WorkletGlobalScope`[p1184] is, at a minimum, tied to the `Document`[p127] whose worklet global scopes[p1189] contain it. In particular, destroying[p1023] the `Document`[p127] will terminate[p1186] the corresponding `WorkletGlobalScope`[p1184] and allow it to be garbage-collected.

Additionally, user agents may, at any time, terminate[p1186] a given `WorkletGlobalScope`[p1184], unless the specification defining the corresponding worklet type says otherwise. For example, they might terminate them if the worklet agent[p1028]'s event loop[p1071] has no tasks[p1071] queued, or if the user agent has no pending operations planning to make use of the worklet, or if the user agent detects abnormal operations such as infinite loops or callbacks exceeding imposed time limits.

Finally, specifications for specific worklet types can give more specific details on when to create[p1185] `WorkletGlobalScope`[p1184]s for a given worklet type. For example, they might create them during specific processes that call upon worklet code, as in the example[p1184].

12 Web storage §p11 90

12.1 Introduction §p11 90

This section is non-normative.

This specification introduces two related mechanisms, similar to HTTP session cookies, for storing name-value pairs on the client side. [COOKIES]p1411

The first is designed for scenarios where the user is carrying out a single transaction, but could be carrying out multiple transactions in different windows at the same time.

Cookies don't really handle this case well. For example, a user could be buying plane tickets in two different windows, using the same site. If the site used cookies to keep track of which ticket the user was buying, then as the user clicked from page to page in both windows, the ticket currently being purchased would "leak" from one window to the other, potentially causing the user to buy two tickets for the same flight without noticing.

To address this, this specification introduces the `sessionStorage`p1193 getter. Sites can add data to the session storage, and it will be accessible to any page from the same site opened in that window.

Example

For example, a page could have a checkbox that the user ticks to indicate that they want insurance:

```
<label>
 <input type="checkbox" onchange="sessionStorage.insurance = checked ? 'true' : ''">
  I want insurance on this trip.
</label>
```

A later page could then check, from script, whether the user had checked the checkbox or not:

```
if (sessionStorage.insurance) { ... }
```

If the user had multiple windows opened on the site, each one would have its own individual copy of the session storage object.

The second storage mechanism is designed for storage that spans multiple windows, and lasts beyond the current session. In particular, web applications might wish to store megabytes of user data, such as entire user-authored documents or a user's mailbox, on the client side for performance reasons.

Again, cookies do not handle this case well, because they are transmitted with every request.

The `localStorage`p1194 getter is used to access a page's local storage area.

Example

The site at example.com can display a count of how many times the user has loaded its page by putting the following at the bottom of its page:

```
<p>
  You have viewed this page
  <span id="count">an untold number of</span>
  time(s).
</p>
<script>
  if (!localStorage.pageLoadCount)
    localStorage.pageLoadCount = 0;
```

```
  localStorage.pageLoadCount = parseInt(localStorage.pageLoadCount) + 1;
  document.getElementById('count').textContent = localStorage.pageLoadCount;
</script>
```

Each site has its own separate storage area.

⚠Warning!

The localStorage[p1194] getter provides access to shared state. This specification does not define the interaction with other agent clusters in a multiprocess user agent, and authors are encouraged to assume that there is no locking mechanism. A site could, for instance, try to read the value of a key, increment its value, then write it back out, using the new value as a unique identifier for the session; if the site does this twice in two different browser windows at the same time, it might end up using the same "unique" identifier for both sessions, with potentially disastrous effects.

✔ MDN

12.2 The API §[p1191]

12.2.1 The Storage[p1191] interface §[p1191]

IDL

```
[Exposed=Window]
interface Storage {
  readonly attribute unsigned long length;
  DOMString? key(unsigned long index);
  getter DOMString? getItem(DOMString key);
  setter undefined setItem(DOMString key, DOMString value);
  deleter undefined removeItem(DOMString key);
  undefined clear();
};
```

For web developers (non-normative)

***storage*.length[p1192]**

Returns the number of key/value pairs.

***storage*.key[p1192] (*n*)**

Returns the name of the *n*th key, or null if *n* is greater than or equal to the number of key/value pairs.

***value* = *storage*.getItem[p1192] (*key*)**

***value* = *storage*[*key*]**

Returns the current value associated with the given *key*, or null if the given *key* does not exist.

***storage*.setItem[p1192] (*key*, *value*)**

storage*[*key*] = *value

Sets the value of the pair identified by *key* to *value*, creating a new key/value pair if none existed for *key* previously.

Throws a "QuotaExceededError" DOMException exception if the new value couldn't be set. (Setting could fail if, e.g., the user has disabled storage for the site, or if the quota has been exceeded.)

Dispatches a storage[p1407] event on Window[p892] objects holding an equivalent Storage[p1191] object.

***storage*.removeItem[p1193] (*key*)**

delete *storage*[*key*]

Removes the key/value pair with the given *key*, if a key/value pair with the given *key* exists.

Dispatches a storage[p1407] event on Window[p892] objects holding an equivalent Storage[p1191] object.

***storage*.clear[p1193]()**

Removes all key/value pairs, if there are any.

Dispatches a storage[p1407] event on Window[p892] objects holding an equivalent Storage[p1191] object.

A Storage[p1191] object has an associated:

map

A storage proxy map.

type

"local" or "session".

To **reorder** a Storage[p1191] object *storage*, reorder *storage*'s map[p1192]'s entries in an implementation-defined manner.

Note

Unfortunate as it is, iteration order is not defined and can change upon most mutations.

To **broadcast** a Storage[p1191] object *storage*, given a *key*, *oldValue*, and *newValue*, run these steps:

1. Let *thisDocument* be *storage*'s relevant global object[p1039]'s associated Document[p894].
2. Let *url* be *thisDocument*'s URL.
3. Let *remoteStorages* be all Storage[p1191] objects excluding *storage* whose:
   - type[p1192] is *storage*'s type[p1192]
   - relevant settings object[p1039]'s origin[p869] is same origin[p870] with *storage*'s relevant settings object[p1039]'s origin[p869].

   and, if type[p1192] is "session", whose relevant settings object[p1039]'s associated Document[p894]'s node navigable[p953]'s traversable navigable[p953] is *thisDocument*'s node navigable[p953]'s traversable navigable[p953].
4. For each *remoteStorage* of *remoteStorages*: queue a global task[p1073] on the DOM manipulation task source[p1080] given *remoteStorage*'s relevant global object[p1039] to fire an event named storage[p1407] at *remoteStorage*'s relevant global object[p1039], using StorageEvent[p1194], with key[p1195] initialized to *key*, oldValue[p1195] initialized to *oldValue*, newValue[p1195] initialized to *newValue*, url[p1195] initialized to *url*, and storageArea[p1195] initialized to *remoteStorage*.

   Note

   The Document[p127] object associated with the resulting task[p1071] is not necessarily fully active[p966], but events fired on such objects are ignored by the event loop[p1071] until the Document[p127] becomes fully active[p966] again.

The **length** getter steps are to return this's map[p1192]'s size.

The **key(*index*)** method steps are:

1. If *index* is greater than or equal to this's map[p1192]'s size, then return null.
2. Let *keys* be the result of running get the keys on this's map[p1192].
3. Return *keys*[*index*].

The supported property names on a Storage[p1191] object *storage* are the result of running get the keys on *storage*'s map[p1192].

The **getItem(*key*)** method steps are:

1. If this's map[p1192][*key*] does not exist, then return null.
2. Return this's map[p1192][*key*].

The **setItem(*key*, *value*)** method are:

1. Let *oldValue* be null.

2. Let *reorder* be true.
3. If this's map[p1192][*key*] exists:
    1. Set *oldValue* to this's map[p1192][*key*].
    2. If *oldValue* is *value*, then return.
    3. Set *reorder* to false.
4. If *value* cannot be stored, then throw a "QuotaExceededError" DOMException exception.
5. Set this's map[p1192][*key*] to *value*.
6. If *reorder* is true, then reorder[p1192] this.
7. Broadcast[p1192] this with *key*, *oldValue*, and *value*.

The **removeItem(*key*)** method steps are:

1. If this's map[p1192][*key*] does not exist, then return null.
2. Set *oldValue* to this's map[p1192][*key*].
3. Remove this's map[p1192][*key*].
4. Reorder[p1192] this.
5. Broadcast[p1192] this with *key*, *oldValue*, and null.

The **clear()** method steps are:

1. Clear this's map[p1192].
2. Broadcast[p1192] this with null, null, and null.

12.2.2 The sessionStorage[p1193] getter §[p1193]

```
IDL
interface mixin WindowSessionStorage {
  readonly attribute Storage sessionStorage;
};
Window includes WindowSessionStorage;
```

For web developers (non-normative)

***window*.sessionStorage**[p1193]

Returns the Storage[p1191] object associated with that *window*'s origin's session storage area.

Throws a "SecurityError" DOMException if the Document[p127]'s origin is an opaque origin[p869] or if the request violates a policy decision (e.g., if the user agent is configured to not allow the page to persist data).

A Document[p127] object has an associated **session storage holder**, which is null or a Storage[p1191] object. It is initially null.

The **sessionStorage** getter steps are:

1. If this's associated Document[p894]'s session storage holder[p1193] is non-null, then return this's associated Document[p894]'s session storage holder[p1193].
2. Let *map* be the result of running obtain a session storage bottle map with this's relevant settings object[p1039] and "sessionStorage".
3. If *map* is failure, then throw a "SecurityError" DOMException.
4. Let *storage* be a new Storage[p1191] object whose map[p1192] is *map*.
5. Set this's associated Document[p894]'s session storage holder[p1193] to *storage*.

6. Return *storage*.

Note

After creating a new auxiliary browsing context and document[p963], the session storage is copied[p954] over.

12.2.3 The localStorage[p1194] getter §[p1194]

```
IDL
interface mixin WindowLocalStorage {
  readonly attribute Storage localStorage;
};
Window includes WindowLocalStorage;
```

For web developers (non-normative)

***window*.localStorage[p1194]**

Returns the Storage[p1191] object associated with *window*'s origin's local storage area.

Throws a "SecurityError" DOMException if the Document[p127]'s origin is an opaque origin[p869] or if the request violates a policy decision (e.g., if the user agent is configured to not allow the page to persist data).

A Document[p127] object has an associated **local storage holder**, which is null or a Storage[p1191] object. It is initially null.

The **localStorage** getter steps are:

1. If this's associated Document[p894]'s local storage holder[p1194] is non-null, then return this's associated Document[p894]'s local storage holder[p1194].
2. Let *map* be the result of running obtain a local storage bottle map with this's relevant settings object[p1039] and "localStorage".
3. If *map* is failure, then throw a "SecurityError" DOMException.
4. Let *storage* be a new Storage[p1191] object whose map[p1192] is *map*.
5. Set this's associated Document[p894]'s local storage holder[p1194] to *storage*.
6. Return *storage*.

✔ MDN

12.2.4 The StorageEvent[p1194] interface §[p1194]

```
IDL
[Exposed=Window]
interface StorageEvent : Event {
  constructor(DOMString type, optional StorageEventInit eventInitDict = {});

  readonly attribute DOMString? key;
  readonly attribute DOMString? oldValue;
  readonly attribute DOMString? newValue;
  readonly attribute USVString url;
  readonly attribute Storage? storageArea;

  undefined initStorageEvent(DOMString type, optional boolean bubbles = false, optional boolean
cancelable = false, optional DOMString? key = null, optional DOMString? oldValue = null, optional
DOMString? newValue = null, optional USVString url = "", optional Storage? storageArea = null);
};

dictionary StorageEventInit : EventInit {
  DOMString? key = null;
  DOMString? oldValue = null;
```

```
  DOMString? newValue = null;
  USVString url = "";
  Storage? storageArea = null;
};
```

For web developers (non-normative)

***event*.key**[p1195]

Returns the key of the storage item being changed.

***event*.oldValue**[p1195]

Returns the old value of the key of the storage item whose value is being changed.

***event*.newValue**[p1195]

Returns the new value of the key of the storage item whose value is being changed.

***event*.url**[p1195]

Returns the URL of the document whose storage item changed.

***event*.storageArea**[p1195]

Returns the `Storage`[p1191] object that was affected.

The **key**, **oldValue**, **newValue**, **url**, and **storageArea** attributes must return the values they were initialized to.

The **initStorageEvent(*type, bubbles, cancelable, key, oldValue, newValue, url, storageArea*)** method must initialize the event in a manner analogous to the similarly-named `initEvent()` method. [DOM][p1412]

12.3 Privacy §[p1195]

12.3.1 User tracking §[p1195]

A third-party advertiser (or any entity capable of getting content distributed to multiple sites) could use a unique identifier stored in its local storage area to track a user across multiple sessions, building a profile of the user's interests to allow for highly targeted advertising. In conjunction with a site that is aware of the user's real identity (for example an e-commerce site that requires authenticated credentials), this could allow oppressive groups to target individuals with greater accuracy than in a world with purely anonymous web usage.

There are a number of techniques that can be used to mitigate the risk of user tracking:

Blocking third-party storage

User agents may restrict access to the `localStorage`[p1194] objects to scripts originating at the domain of the active document[p952] of the top-level traversable[p953], for instance denying access to the API for pages from other domains running in `iframe`[p383]s.

Expiring stored data

User agents may, possibly in a manner configured by the user, automatically delete stored data after a period of time.

For example, a user agent could be configured to treat third-party local storage areas as session-only storage, deleting the data once the user had closed all the navigables[p952] that could access it.

This can restrict the ability of a site to track a user, as the site would then only be able to track the user across multiple sessions when they authenticate with the site itself (e.g. by making a purchase or logging in to a service).

However, this also reduces the usefulness of the API as a long-term storage mechanism. It can also put the user's data at risk, if the user does not fully understand the implications of data expiration.

Treating persistent storage as cookies

If users attempt to protect their privacy by clearing cookies without also clearing data stored in the local storage area, sites can defeat those attempts by using the two features as redundant backup for each other. User agents should present the interfaces for clearing these in a way that helps users to understand this possibility and enables them to delete data in all persistent storage features simultaneously. [COOKIES][p1411]

Site-specific safelisting of access to local storage areas

User agents may allow sites to access session storage areas in an unrestricted manner, but require the user to authorize access to local storage areas.

Origin-tracking of stored data

User agents may record the origins[p869] of sites that contained content from third-party origins that caused data to be stored.

If this information is then used to present the view of data currently in persistent storage, it would allow the user to make informed decisions about which parts of the persistent storage to prune. Combined with a blocklist ("delete this data and prevent this domain from ever storing data again"), the user can restrict the use of persistent storage to sites that they trust.

Shared blocklists

User agents may allow users to share their persistent storage domain blocklists.

This would allow communities to act together to protect their privacy.

While these suggestions prevent trivial use of this API for user tracking, they do not block it altogether. Within a single domain, a site can continue to track the user during a session, and can then pass all this information to the third party along with any identifying information (names, credit card numbers, addresses) obtained by the site. If a third party cooperates with multiple sites to obtain such information, a profile can still be created.

However, user tracking is to some extent possible even with no cooperation from the user agent whatsoever, for instance by using session identifiers in URLs, a technique already commonly used for innocuous purposes but easily repurposed for user tracking (even retroactively). This information can then be shared with other sites, using visitors' IP addresses and other user-specific data (e.g. user-agent headers and configuration settings) to combine separate sessions into coherent user profiles.

12.3.2 Sensitivity of data §[p11 96]

User agents should treat persistently stored data as potentially sensitive; it's quite possible for emails, calendar appointments, health records, or other confidential documents to be stored in this mechanism.

To this end, user agents should ensure that when deleting data, it is promptly deleted from the underlying storage.

12.4 Security §[p11 96]

12.4.1 DNS spoofing attacks §[p11 96]

Because of the potential for DNS spoofing attacks, one cannot guarantee that a host claiming to be in a certain domain really is from that domain. To mitigate this, pages can use TLS. Pages using TLS can be sure that only the user, software working on behalf of the user, and other pages using TLS that have certificates identifying them as being from the same domain, can access their storage areas.

12.4.2 Cross-directory attacks §[p11 96]

Different authors sharing one host name, for example users hosting content on the now defunct `geocities.com`, all share one local storage object. There is no feature to restrict the access by pathname. Authors on shared hosts are therefore urged to avoid using these features, as it would be trivial for other authors to read the data and overwrite it.

Note

Even if a path-restriction feature was made available, the usual DOM scripting security model would make it trivial to bypass this protection and access the data from any path.

12.4.3 Implementation risks §p11 97

The two primary risks when implementing these persistent storage features are letting hostile sites read information from other domains, and letting hostile sites write information that is then read from other domains.

Letting third-party sites read data that is not supposed to be read from their domain causes *information leakage*. For example, a user's shopping wishlist on one domain could be used by another domain for targeted advertising; or a user's work-in-progress confidential documents stored by a word-processing site could be examined by the site of a competing company.

Letting third-party sites write data to the persistent storage of other domains can result in *information spoofing*, which is equally dangerous. For example, a hostile site could add items to a user's wishlist; or a hostile site could set a user's session identifier to a known ID that the hostile site can then use to track the user's actions on the victim site.

Thus, strictly following the origin p869 model described in this specification is important for user security.

13 The HTML syntax §p11 98

Note

This section only describes the rules for resources labeled with an HTML MIME type. Rules for XML resources are discussed in the section below entitled "The XML syntax p1321".

13.1 Writing HTML documents §p11 98

This section only applies to documents, authoring tools, and markup generators. In particular, it does not apply to conformance checkers; conformance checkers must use the requirements given in the next section ("parsing HTML documents").

Documents must consist of the following parts, in the given order:

1. Optionally, a single U+FEFF BYTE ORDER MARK (BOM) character.
2. Any number of comments p1209 and ASCII whitespace.
3. A DOCTYPE p1198.
4. Any number of comments p1209 and ASCII whitespace.
5. The document element, in the form of an `html` p167 element p1199.
6. Any number of comments p1209 and ASCII whitespace.

The various types of content mentioned above are described in the next few sections.

In addition, there are some restrictions on how character encoding declarations p194 are to be serialized, as discussed in the section on that topic.

Note

ASCII whitespace before the `html` p167 element, at the start of the `html` p167 element and before the `head` p168 element, will be dropped when the document is parsed; ASCII whitespace after the `html` p167 element will be parsed as if it were at the end of the `body` p199 element. Thus, ASCII whitespace around the document element does not round-trip.

It is suggested that newlines be inserted after the DOCTYPE, after any comments that are before the document element, after the `html` p167 element's start tag (if it is not omitted p1202), and after any comments that are inside the `html` p167 element but before the `head` p168 element.

Many strings in the HTML syntax (e.g. the names of elements and their attributes) are case-insensitive, but only for ASCII upper alphas and ASCII lower alphas. For convenience, in this section this is just referred to as "case-insensitive".

13.1.1 The DOCTYPE §p11 98

A **DOCTYPE** is a required preamble.

Note

DOCTYPEs are required for legacy reasons. When omitted, browsers tend to use a different rendering mode that is incompatible with some specifications. Including the DOCTYPE in a document ensures that the browser makes a best-effort attempt at following the relevant specifications.

A DOCTYPE must consist of the following components, in this order:

1. A string that is an ASCII case-insensitive match for the string "`<!DOCTYPE`".
2. One or more ASCII whitespace.

3. A string that is an ASCII case-insensitive match for the string "`html`".
4. Optionally, a DOCTYPE legacy string[p1199].
5. Zero or more ASCII whitespace.
6. A U+003E GREATER-THAN SIGN character (>).

Note

In other words, `<!DOCTYPE html>`*, case-insensitively.*

For the purposes of HTML generators that cannot output HTML markup with the short DOCTYPE "`<!DOCTYPE html>`", a **DOCTYPE legacy string** may be inserted into the DOCTYPE (in the position defined above). This string must consist of:

1. One or more ASCII whitespace.
2. A string that is an ASCII case-insensitive match for the string "`SYSTEM`".
3. One or more ASCII whitespace.
4. A U+0022 QUOTATION MARK or U+0027 APOSTROPHE character (the *quote mark*).
5. The literal string "`about:legacy-compat`[p94]".
6. A matching U+0022 QUOTATION MARK or U+0027 APOSTROPHE character (i.e. the same character as in the earlier step labeled *quote mark*).

Note

In other words, `<!DOCTYPE html SYSTEM "about:legacy-compat">` *or* `<!DOCTYPE html SYSTEM 'about:legacy-compat'>`*, case-insensitively except for the part in single or double quotes.*

The DOCTYPE legacy string[p1199] should not be used unless the document is generated from a system that cannot output the shorter string.

13.1.2 Elements §[p11] [99]

There are six different kinds of **elements**: void elements[p1199], the `template` element[p1199], raw text elements[p1199], escapable raw text elements[p1199], foreign elements[p1199], and normal elements[p1199].

Void elements

`area`[p463], `base`[p170], `br`[p294], `col`[p479], `embed`[p391], `hr`[p226], `img`[p338], `input`[p512], `link`[p172], `meta`[p184], `source`[p335], `track`[p403], `wbr`[p295]

The `template` element

`template`[p656]

Raw text elements

`script`[p638], `style`[p195]

Escapable raw text elements

`textarea`[p570], `title`[p169]

Foreign elements

Elements from the MathML namespace and the SVG namespace.

Normal elements

All other allowed HTML elements[p45] are normal elements.

Tags are used to delimit the start and end of elements in the markup. Raw text[p1199], escapable raw text[p1199], and normal[p1199] elements have a start tag[p1200] to indicate where they begin, and an end tag[p1201] to indicate where they end. The start and end tags of certain normal elements[p1199] can be omitted[p1202], as described below in the section on optional tags[p1202]. Those that cannot be omitted must not be omitted. Void elements[p1199] only have a start tag; end tags must not be specified for void elements[p1199]. Foreign elements[p1199] must either have a start tag and an end tag, or a start tag that is marked as self-closing, in which case they must not have an end tag.

The contents[p144] of the element must be placed between just after the start tag (which might be implied, in certain cases[p1202]) and just before the end tag (which again, might be implied in certain cases[p1202]). The exact allowed contents of each individual element depend on the content model[p144] of that element, as described earlier in this specification. Elements must not contain content that their content model disallows. In addition to the restrictions placed on the contents by those content models, however, the five types of elements have additional *syntactic* requirements.

Void elements[p1199] can't have any contents (since there's no end tag, no content can be put between the start tag and the end tag).

The `template` element[p1199] can have template contents[p657], but such template contents[p657] are not children of the `template`[p656] element itself. Instead, they are stored in a `DocumentFragment` associated with a different `Document`[p127] — without a browsing context[p961] — so as to avoid the `template`[p656] contents interfering with the main `Document`[p127]. The markup for the template contents[p657] of a `template`[p656] element is placed just after the `template`[p656] element's start tag and just before `template`[p656] element's end tag (as with other elements), and may consist of any text[p1208], character references[p1208], elements[p1199], and comments[p1209], but the text must not contain the character U+003C LESS-THAN SIGN (<) or an ambiguous ampersand[p1209].

Raw text elements[p1199] can have text[p1208], though it has restrictions[p1208] described below.

Escapable raw text elements[p1199] can have text[p1208] and character references[p1208], but the text must not contain an ambiguous ampersand[p1209]. There are also further restrictions[p1208] described below.

Foreign elements[p1199] whose start tag is marked as self-closing can't have any contents (since, again, as there's no end tag, no content can be put between the start tag and the end tag). Foreign elements[p1199] whose start tag is *not* marked as self-closing can have text[p1208], character references[p1208], CDATA sections[p1209], other elements[p1199], and comments[p1209], but the text must not contain the character U+003C LESS-THAN SIGN (<) or an ambiguous ampersand[p1209].

Note

The HTML syntax does not support namespace declarations, even in foreign elements[p1199].

For instance, consider the following HTML fragment:

```
<p>
 <svg>
  <metadata>
   <!-- this is invalid -->
   <cdr:license xmlns:cdr="https://www.example.com/cdr/metadata" name="MIT"/>
  </metadata>
 </svg>
</p>
```

The innermost element, `cdr:license`*, is actually in the SVG namespace, as the* "`xmlns:cdr`" *attribute has no effect (unlike in XML). In fact, as the comment in the fragment above says, the fragment is actually non-conforming. This is because* SVG 2 *does not define any elements called* "`cdr:license`" *in the SVG namespace.*

Normal elements[p1199] can have text[p1208], character references[p1208], other elements[p1199], and comments[p1209], but the text must not contain the character U+003C LESS-THAN SIGN (<) or an ambiguous ampersand[p1209]. Some normal elements[p1199] also have yet more restrictions[p1208] on what content they are allowed to hold, beyond the restrictions imposed by the content model and those described in this paragraph. Those restrictions are described below.

Tags contain a **tag name**, giving the element's name. HTML elements all have names that only use ASCII alphanumerics. In the HTML syntax, tag names, even those for foreign elements[p1199], may be written with any mix of lower- and uppercase letters that, when converted to all-lowercase, matches the element's tag name; tag names are case-insensitive.

13.1.2.1 Start tags §[p1200]

Start tags must have the following format:

1. The first character of a start tag must be a U+003C LESS-THAN SIGN character (<).
2. The next few characters of a start tag must be the element's tag name[p1200].
3. If there are to be any attributes in the next step, there must first be one or more ASCII whitespace.
4. Then, the start tag may have a number of attributes, the syntax for which[p1201] is described below. Attributes must be separated from each other by one or more ASCII whitespace.
5. After the attributes, or after the tag name[p1200] if there are no attributes, there may be one or more ASCII whitespace. (Some attributes are required to be followed by a space. See the attributes section[p1201] below.)
6. Then, if the element is one of the void elements[p1199], or if the element is a foreign element[p1199], then there may be a single U+002F SOLIDUS character (/), which on foreign elements[p1199] marks the start tag as self-closing. On void elements[p1199], it

does not mark the start tag as self-closing but instead is unnecessary and has no effect of any kind. For such void elements, it should be used only with caution — especially since, if directly preceded by an unquoted attribute value[p1201], it becomes part of the attribute value rather than being discarded by the parser.

7. Finally, start tags must be closed by a U+003E GREATER-THAN SIGN character (>).

13.1.2.2 End tags §[p1201]

End tags must have the following format:

1. The first character of an end tag must be a U+003C LESS-THAN SIGN character (<).
2. The second character of an end tag must be a U+002F SOLIDUS character (/).
3. The next few characters of an end tag must be the element's tag name[p1200].
4. After the tag name, there may be one or more ASCII whitespace.
5. Finally, end tags must be closed by a U+003E GREATER-THAN SIGN character (>).

13.1.2.3 Attributes §[p1201]

Attributes for an element are expressed inside the element's start tag.

Attributes have a name and a value. **Attribute names** must consist of one or more characters other than controls, U+0020 SPACE, U+0022 ("), U+0027 ('), U+003E (>), U+002F (/), U+003D (=), and noncharacters. In the HTML syntax, attribute names, even those for foreign elements[p1199], may be written with any mix of ASCII lower and ASCII upper alphas.

Attribute values are a mixture of text[p1208] and character references[p1208], except with the additional restriction that the text cannot contain an ambiguous ampersand[p1209].

Attributes can be specified in four different ways:

Empty attribute syntax

Just the attribute name[p1201]. The value is implicitly the empty string.

Example

In the following example, the disabled[p591] attribute is given with the empty attribute syntax:

```
<input disabled>
```

If an attribute using the empty attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.

Unquoted attribute value syntax

The attribute name[p1201], followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by the attribute value[p1201], which, in addition to the requirements given above for attribute values, must not contain any literal ASCII whitespace, any U+0022 QUOTATION MARK characters ("), U+0027 APOSTROPHE characters ('), U+003D EQUALS SIGN characters (=), U+003C LESS-THAN SIGN characters (<), U+003E GREATER-THAN SIGN characters (>), or U+0060 GRAVE ACCENT characters (`), and must not be the empty string.

Example

In the following example, the value[p516] attribute is given with the unquoted attribute value syntax:

```
<input value=yes>
```

If an attribute using the unquoted attribute syntax is to be followed by another attribute or by the optional U+002F SOLIDUS character (/) allowed in step 6 of the start tag[p1200] syntax above, then there must be ASCII whitespace separating the two.

Single-quoted attribute value syntax

The attribute name[p1201], followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by a single U+0027 APOSTROPHE character ('), followed by the attribute value[p1201], which, in addition to the requirements given above for attribute values, must not contain any literal U+0027 APOSTROPHE characters ('), and finally followed by a second single U+0027 APOSTROPHE character (').

Example

In the following example, the type[p514] attribute is given with the single-quoted attribute value syntax:

```
<input type='checkbox'>
```

If an attribute using the single-quoted attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.

Double-quoted attribute value syntax

The attribute name[p1201], followed by zero or more ASCII whitespace, followed by a single U+003D EQUALS SIGN character, followed by zero or more ASCII whitespace, followed by a single U+0022 QUOTATION MARK character ("), followed by the attribute value[p1201], which, in addition to the requirements given above for attribute values, must not contain any literal U+0022 QUOTATION MARK characters ("), and finally followed by a second single U+0022 QUOTATION MARK character (").

Example

In the following example, the name[p589] attribute is given with the double-quoted attribute value syntax:

```
<input name="be evil">
```

If an attribute using the double-quoted attribute syntax is to be followed by another attribute, then there must be ASCII whitespace separating the two.

There must never be two or more attributes on the same start tag whose names are an ASCII case-insensitive match for each other.

When a foreign element[p1199] has one of the namespaced attributes given by the local name and namespace of the first and second cells of a row from the following table, it must be written using the name given by the third cell from the same row.

Local name	Namespace	Attribute name
actuate	XLink namespace	xlink:actuate
arcrole	XLink namespace	xlink:arcrole
href	XLink namespace	xlink:href
role	XLink namespace	xlink:role
show	XLink namespace	xlink:show
title	XLink namespace	xlink:title
type	XLink namespace	xlink:type
lang	XML namespace	xml:lang
space	XML namespace	xml:space
xmlns	XMLNS namespace	xmlns
xlink	XMLNS namespace	xmlns:xlink

No other namespaced attribute can be expressed in the HTML syntax[p1198].

Note

Whether the attributes in the table above are conforming or not is defined by other specifications (e.g. SVG 2 and MathML); this section only describes the syntax rules if the attributes are serialized using the HTML syntax.

13.1.2.4 Optional tags §[p1202]

Certain tags can be **omitted**.

Note

Omitting an element's start tag[p1200] in the situations described below does not mean the element is not present; it is implied, but it is still there. For example, an HTML document always has a root `html`[p167] element, even if the string `<html>` doesn't appear anywhere in the markup.

An `html`[p167] element's start tag[p1200] may be omitted if the first thing inside the `html`[p167] element is not a comment[p1209].

Example

For example, in the following case it's ok to remove the "`<html>`" tag:

```
<!DOCTYPE HTML>
<html>
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

Doing so would make the document look like this:

```
<!DOCTYPE HTML>

  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

This has the exact same DOM. In particular, note that whitespace around the document element is ignored by the parser. The following example would also have the exact same DOM:

```
<!DOCTYPE HTML><head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

However, in the following example, removing the start tag moves the comment to before the `html`[p167] element:

```
<!DOCTYPE HTML>
<html>
  <!-- where is this comment in the DOM? -->
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

With the tag removed, the document actually turns into the same as this:

```
<!DOCTYPE HTML>
```

```
<!-- where is this comment in the DOM? -->
<html>
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

This is why the tag can only be removed if it is not followed by a comment: removing the tag when there is a comment there changes the document's resulting parse tree. Of course, if the position of the comment does not matter, then the tag can be omitted, as if the comment had been moved to before the start tag in the first place.

An html[p167] element's end tag[p1201] may be omitted if the html[p167] element is not immediately followed by a comment[p1209].

A head[p168] element's start tag[p1200] may be omitted if the element is empty, or if the first thing inside the head[p168] element is an element.

A head[p168] element's end tag[p1201] may be omitted if the head[p168] element is not immediately followed by ASCII whitespace or a comment[p1209].

A body[p199] element's start tag[p1200] may be omitted if the element is empty, or if the first thing inside the body[p199] element is not ASCII whitespace or a comment[p1209], except if the first thing inside the body[p199] element is a meta[p184], noscript[p654], link[p172], script[p638], style[p195], or template[p656] element.

A body[p199] element's end tag[p1201] may be omitted if the body[p199] element is not immediately followed by a comment[p1209].

Example

Note that in the example above, the head[p168] element start and end tags, and the body[p199] element start tag, can't be omitted, because they are surrounded by whitespace:

```
<!DOCTYPE HTML>
<html>
  <head>
    <title>Hello</title>
  </head>
  <body>
    <p>Welcome to this example.</p>
  </body>
</html>
```

(The body[p199] and html[p167] element end tags could be omitted without trouble; any spaces after those get parsed into the body[p199] element anyway.)

Usually, however, whitespace isn't an issue. If we first remove the whitespace we don't care about:

```
<!DOCTYPE HTML><html><head><title>Hello</title></head><body><p>Welcome to this
example.</p></body></html>
```

Then we can omit a number of tags without affecting the DOM:

```
<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.</p>
```

At that point, we can also add some whitespace back:

```
<!DOCTYPE HTML>
<title>Hello</title>
```

```
<p>Welcome to this example.</p>
```

This would be equivalent to this document, with the omitted tags shown in their parser-implied positions; the only whitespace text node that results from this is the newline at the end of the head[p168] element:

```
<!DOCTYPE HTML>
<html><head><title>Hello</title>
</head><body><p>Welcome to this example.</p></body></html>
```

An li[p236] element's end tag[p1201] may be omitted if the li[p236] element is immediately followed by another li[p236] element or if there is no more content in the parent element.

A dt[p242] element's end tag[p1201] may be omitted if the dt[p242] element is immediately followed by another dt[p242] element or a dd[p243] element.

A dd[p243] element's end tag[p1201] may be omitted if the dd[p243] element is immediately followed by another dd[p243] element or a dt[p242] element, or if there is no more content in the parent element.

A p[p223] element's end tag[p1201] may be omitted if the p[p223] element is immediately followed by an address[p217], article[p201], aside[p209], blockquote[p229], details[p627], div[p251], dl[p238], fieldset[p584], figcaption[p247], figure[p244], footer[p214], form[p505], h1[p211], h2[p211], h3[p211], h4[p211], h5[p211], h6[p211], header[p213], hgroup[p212], hr[p226], main[p247], menu[p235], nav[p206], ol[p232], p[p223], pre[p228], search[p249], section[p203], table[p469], or ul[p234] element, or if there is no more content in the parent element and the parent element is an HTML element[p45] that is not an a[p252], audio[p402], del[p331], ins[p329], map[p461], noscript[p654], or video[p398] element, or an autonomous custom element[p742].

Example

We can thus simplify the earlier example further:

```
<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.
```

An rt[p271] element's end tag[p1201] may be omitted if the rt[p271] element is immediately followed by an rt[p271] or rp[p272] element, or if there is no more content in the parent element.

An rp[p272] element's end tag[p1201] may be omitted if the rp[p272] element is immediately followed by an rt[p271] or rp[p272] element, or if there is no more content in the parent element.

An optgroup[p566] element's end tag[p1201] may be omitted if the optgroup[p566] element is immediately followed by another optgroup[p566] element, if it is immediately followed by an hr[p226] element, or if there is no more content in the parent element.

An option[p567] element's end tag[p1201] may be omitted if the option[p567] element is immediately followed by another option[p567] element, if it is immediately followed by an optgroup[p566] element, if it is immediately followed by an hr[p226] element, or if there is no more content in the parent element.

A colgroup[p478] element's start tag[p1200] may be omitted if the first thing inside the colgroup[p478] element is a col[p479] element, and if the element is not immediately preceded by another colgroup[p478] element whose end tag[p1201] has been omitted. (It can't be omitted if the element is empty.)

A colgroup[p478] element's end tag[p1201] may be omitted if the colgroup[p478] element is not immediately followed by ASCII whitespace or a comment[p1209].

A caption[p477] element's end tag[p1201] may be omitted if the caption[p477] element is not immediately followed by ASCII whitespace or a comment[p1209].

A thead[p481] element's end tag[p1201] may be omitted if the thead[p481] element is immediately followed by a tbody[p480] or tfoot[p482] element.

A tbody[p480] element's start tag[p1200] may be omitted if the first thing inside the tbody[p480] element is a tr[p483] element, and if the element is not immediately preceded by a tbody[p480], thead[p481], or tfoot[p482] element whose end tag[p1201] has been omitted. (It can't be omitted if the element is empty.)

A tbody[p480] element's end tag[p1201] may be omitted if the tbody[p480] element is immediately followed by a tbody[p480] or tfoot[p482]

element, or if there is no more content in the parent element.

A tfoot[p482] element's end tag[p1201] may be omitted if there is no more content in the parent element.

A tr[p483] element's end tag[p1201] may be omitted if the tr[p483] element is immediately followed by another tr[p483] element, or if there is no more content in the parent element.

A td[p484] element's end tag[p1201] may be omitted if the td[p484] element is immediately followed by a td[p484] or th[p486] element, or if there is no more content in the parent element.

A th[p486] element's end tag[p1201] may be omitted if the th[p486] element is immediately followed by a td[p484] or th[p486] element, or if there is no more content in the parent element.

Example

The ability to omit all these table-related tags makes table markup much terser.

Take this example:

```
<table>
 <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)</caption>
 <colgroup><col><col><col></colgroup>
 <thead>
  <tr>
   <th>Function</th>
   <th>Control Unit</th>
   <th>Central Station</th>
  </tr>
 </thead>
 <tbody>
  <tr>
   <td>Headlights</td>
   <td>✔</td>
   <td>✔</td>
  </tr>
  <tr>
   <td>Interior Lights</td>
   <td>✔</td>
   <td>✔</td>
  </tr>
  <tr>
   <td>Electric locomotive operating sounds</td>
   <td>✔</td>
   <td>✔</td>
  </tr>
  <tr>
   <td>Engineer's cab lighting</td>
   <td></td>
   <td>✔</td>
  </tr>
  <tr>
   <td>Station Announcements - Swiss</td>
   <td></td>
   <td>✔</td>
  </tr>
 </tbody>
</table>
```

The exact same table, modulo some whitespace differences, could be marked up as follows:

```
<table>
 <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)
```

```
 <colgroup><col><col><col>
 <thead>
  <tr>
   <th>Function
   <th>Control Unit
   <th>Central Station
 <tbody>
  <tr>
   <td>Headlights
   <td>✔
   <td>✔
  <tr>
   <td>Interior Lights
   <td>✔
   <td>✔
  <tr>
   <td>Electric locomotive operating sounds
   <td>✔
   <td>✔
  <tr>
   <td>Engineer's cab lighting
   <td>
   <td>✔
  <tr>
   <td>Station Announcements - Swiss
   <td>
   <td>✔
</table>
```

Since the cells take up much less room this way, this can be made even terser by having each row on one line:

```
<table>
 <caption>37547 TEE Electric Powered Rail Car Train Functions (Abbreviated)
 <colgroup><col><col><col>
 <thead>
  <tr> <th>Function                              <th>Control Unit     <th>Central Station
 <tbody>
  <tr> <td>Headlights                            <td>✔               <td>✔
  <tr> <td>Interior Lights                       <td>✔               <td>✔
  <tr> <td>Electric locomotive operating sounds  <td>✔               <td>✔
  <tr> <td>Engineer's cab lighting               <td>               <td>✔
  <tr> <td>Station Announcements - Swiss         <td>               <td>✔
</table>
```

The only differences between these tables, at the DOM level, is with the precise position of the (in any case semantically-neutral) whitespace.

However, a start tag[p1200] must never be omitted if it has any attributes.

Example

Returning to the earlier example with all the whitespace removed and then all the optional tags removed:

```
<!DOCTYPE HTML><title>Hello</title><p>Welcome to this example.
```

If the body[p199] element in this example had to have a class[p151] attribute and the html[p167] element had to have a lang[p154] attribute, the markup would have to become:

```
<!DOCTYPE HTML><html lang="en"><title>Hello</title><body class="demo"><p>Welcome to this example.
```

Note

This section assumes that the document is conforming, in particular, that there are no content model[p144] violations. Omitting tags in the fashion described in this section in a document that does not conform to the content models[p144] described in this specification is likely to result in unexpected DOM differences (this is, in part, what the content models are designed to avoid).

13.1.2.5 Restrictions on content models §[p1208]

For historical reasons, certain elements have extra restrictions beyond even the restrictions given by their content model.

A `table`[p469] element must not contain `tr`[p483] elements, even though these elements are technically allowed inside `table`[p469] elements according to the content models described in this specification. (If a `tr`[p483] element is put inside a `table`[p469] in the markup, it will in fact imply a `tbody`[p480] start tag before it.)

A single newline[p1208] may be placed immediately after the start tag[p1200] of `pre`[p228] and `textarea`[p570] elements. This does not affect the processing of the element. The otherwise optional newline[p1208] *must* be included if the element's contents themselves start with a newline[p1208] (because otherwise the leading newline in the contents would be treated like the optional newline, and ignored).

Example

The following two `pre`[p228] blocks are equivalent:

```
<pre>Hello</pre>
```

```
<pre>
Hello</pre>
```

13.1.2.6 Restrictions on the contents of raw text and escapable raw text elements §[p1208]

The text in raw text[p1199] and escapable raw text elements[p1199] must not contain any occurrences of the string "</" (U+003C LESS-THAN SIGN, U+002F SOLIDUS) followed by characters that case-insensitively match the tag name of the element followed by one of U+0009 CHARACTER TABULATION (tab), U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), U+0020 SPACE, U+003E GREATER-THAN SIGN (>), or U+002F SOLIDUS (/).

13.1.3 Text §[p1208]

Text is allowed inside elements, attribute values, and comments. Extra constraints are placed on what is and what is not allowed in text based on where the text is to be put, as described in the other sections.

13.1.3.1 Newlines §[p1208]

Newlines in HTML may be represented either as U+000D CARRIAGE RETURN (CR) characters, U+000A LINE FEED (LF) characters, or pairs of U+000D CARRIAGE RETURN (CR), U+000A LINE FEED (LF) characters in that order.

Where character references[p1208] are allowed, a character reference of a U+000A LINE FEED (LF) character (but not a U+000D CARRIAGE RETURN (CR) character) also represents a newline[p1208].

13.1.4 Character references §[p1208]

In certain cases described in other sections, text[p1208] may be mixed with **character references**. These can be used to escape characters that couldn't otherwise legally be included in text[p1208].

Character references must start with a U+0026 AMPERSAND character (&). Following this, there are three possible kinds of character references:

Named character references

The ampersand must be followed by one of the names given in the named character references[p1312] section, using the same case. The name must be one that is terminated by a U+003B SEMICOLON character (;).

Decimal numeric character reference

The ampersand must be followed by a U+0023 NUMBER SIGN character (#), followed by one or more ASCII digits, representing a base-ten integer that corresponds to a code point that is allowed according to the definition below. The digits must then be followed by a U+003B SEMICOLON character (;).

Hexadecimal numeric character reference

The ampersand must be followed by a U+0023 NUMBER SIGN character (#), which must be followed by either a U+0078 LATIN SMALL LETTER X character (x) or a U+0058 LATIN CAPITAL LETTER X character (X), which must then be followed by one or more ASCII hex digits, representing a hexadecimal integer that corresponds to a code point that is allowed according to the definition below. The digits must then be followed by a U+003B SEMICOLON character (;).

The numeric character reference forms described above are allowed to reference any code point excluding U+000D CR, noncharacters, and controls other than ASCII whitespace.

An **ambiguous ampersand** is a U+0026 AMPERSAND character (&) that is followed by one or more ASCII alphanumerics, followed by a U+003B SEMICOLON character (;), where these characters do not match any of the names given in the named character references[p1312] section.

13.1.5 CDATA sections §[p1209]

CDATA sections must consist of the following components, in this order:

1. The string "`<![CDATA[`".
2. Optionally, text[p1208], with the additional restriction that the text must not contain the string "`]]>`".
3. The string "`]]>`".

Example

CDATA sections can only be used in foreign content (MathML or SVG). In this example, a CDATA section is used to escape the contents of a MathML `ms` element:

```
<p>You can add a string to a number, but this stringifies the number:</p>
<math>
 <ms><![CDATA[x<y]]></ms>
 <mo>+</mo>
 <mn>3</mn>
 <mo>=</mo>
 <ms><![CDATA[x<y3]]></ms>
</math>
```

13.1.6 Comments §[p1209]

Comments must have the following format:

1. The string "`<!--`".
2. Optionally, text[p1208], with the additional restriction that the text must not start with the string "`>`", nor start with the string "`->`", nor contain the strings "`<!--`", "`-->`", or "`--!>`", nor end with the string "`<!-`".
3. The string "`-->`".

Note

The text[p1208] is allowed to end with the string "`<!`", as in `<!--My favorite operators are > and <!-->`.

13.2 Parsing HTML documents §[p1210]

This section only applies to user agents, data mining tools, and conformance checkers.

Note

The rules for parsing XML documents into DOM trees are covered by the next section, entitled "The XML syntax[p1321]".

User agents must use the parsing rules described in this section to generate the DOM trees from `text/html`[p1380] resources. Together, these rules define what is referred to as the **HTML parser**.

Note

While the HTML syntax described in this specification bears a close resemblance to SGML and XML, it is a separate language with its own parsing rules.

Some earlier versions of HTML (in particular from HTML2 to HTML4) were based on SGML and used SGML parsing rules. However, few (if any) web browsers ever implemented true SGML parsing for HTML documents; the only user agents to strictly handle HTML as an SGML application have historically been validators. The resulting confusion — with validators claiming documents to have one representation while widely deployed web browsers interoperably implemented a different representation — has wasted decades of productivity. This version of HTML thus returns to a non-SGML basis.

Authors interested in using SGML tools in their authoring pipeline are encouraged to use XML tools and the XML serialization of HTML.

For the purposes of conformance checkers, if a resource is determined to be in the HTML syntax[p1198], then it is an HTML document.

Note

As stated in the terminology section[p45], references to element types[p45] that do not explicitly specify a namespace always refer to elements in the HTML namespace. For example, if the spec talks about "a `menu`[p235] element", then that is an element with the local name "`menu`", the namespace "`http://www.w3.org/1999/xhtml`", and the interface `HTMLMenuElement`[p235]. Where possible, references to such elements are hyperlinked to their definition.

13.2.1 Overview of the parsing model §[p1211]

The input to the HTML parsing process consists of a stream of code points, which is passed through a tokenization[p1229] stage followed by a tree construction[p1257] stage. The output is a `Document`[p127] object.

Note

Implementations that do not support scripting[p48] do not have to actually create a DOM `Document`[p127] object, but the DOM tree in such cases is still used as the model for the rest of the specification.

In the common case, the data handled by the tokenization stage comes from the network, but it can also come from script[p1096] running in the user agent, e.g. using the `document.write()`[p1099] API.

There is only one set of states for the tokenizer stage and the tree construction stage, but the tree construction stage is reentrant, meaning that while the tree construction stage is handling one token, the tokenizer might be resumed, causing further tokens to be emitted and processed before the first token's processing is complete.

Example

In the following example, the tree construction stage will be called upon to handle a "p" start tag token while handling the "script" end tag token:

```
...
<script>
 document.write('<p>');
</script>
...
```

To handle these cases, parsers have a **script nesting level**, which must be initially set to zero, and a **parser pause flag**, which must be initially set to false.

13.2.2 Parse errors §p1212

This specification defines the parsing rules for HTML documents, whether they are syntactically correct or not. Certain points in the parsing algorithm are said to be parse errors[p1212]. The error handling for parse errors is well-defined (that's the processing rules described throughout this specification), but user agents, while parsing an HTML document, may abort the parser[p1297] at the first parse error[p1212] that they encounter for which they do not wish to apply the rules described in this specification.

Conformance checkers must report at least one parse error condition to the user if one or more parse error conditions exist in the document and must not report parse error conditions if none exist in the document. Conformance checkers may report more than one parse error condition if more than one parse error condition exists in the document.

Note

Parse errors are only errors with the syntax of HTML. In addition to checking for parse errors, conformance checkers will also verify that the document obeys all the other conformance requirements described in this specification.

Some parse errors have dedicated codes outlined in the table below that should be used by conformance checkers in reports.

Error descriptions in the table below are non-normative.

Code	Description
abrupt-closing-of-empty-comment	This error occurs if the parser encounters an empty comment[p1209] that is abruptly closed by a U+003E (>) code point (i.e., `<!-->` or `<!--->`). The parser behaves as if the comment is closed correctly.
abrupt-doctype-public-identifier	This error occurs if the parser encounters a U+003E (>) code point in the DOCTYPE[p1198] public identifier (e.g., `<!DOCTYPE html PUBLIC "foo>`). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the `Document`[p127] to quirks mode.
abrupt-doctype-system-identifier	This error occurs if the parser encounters a U+003E (>) code point in the DOCTYPE[p1198] system identifier (e.g., `<!DOCTYPE html PUBLIC "-//W3C//DTD HTML 4.01//EN" "foo>`). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the `Document`[p127] to quirks mode.
absence-of-digits-in-numeric-character-reference	This error occurs if the parser encounters a numeric character reference[p1208] that doesn't contain any digits (e.g., `&#qux;`). In this case the parser doesn't resolve the character reference.
cdata-in-html-content	This error occurs if the parser encounters a CDATA section[p1209] outside of foreign content (SVG or MathML). The parser treats such CDATA sections (including leading "`[CDATA[`" and trailing "`]]`" strings) as comments.
character-reference-outside-unicode-range	This error occurs if the parser encounters a numeric character reference[p1208] that references a code point that is greater than the valid Unicode range. The parser resolves such a character reference to a U+FFFD REPLACEMENT CHARACTER.
control-character-in-input-stream	This error occurs if the input stream[p1223] contains a control code point that is not ASCII whitespace or U+0000 NULL. Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM.
control-character-reference	This error occurs if the parser encounters a numeric character reference[p1208] that references a control code point that is not ASCII whitespace or is a U+000D CARRIAGE RETURN. The parser resolves such character references as-is except C1 control references that are replaced according to the numeric character reference end state[p1256].
end-tag-with-attributes	This error occurs if the parser encounters an end tag[p1201] with attributes[p1201]. Attributes in end tags are ignored and do not make their way into the DOM.
duplicate-attribute	This error occurs if the parser encounters an attribute[p1201] in a tag that already has an attribute with the same name. The parser ignores all such duplicate occurrences of the attribute.
end-tag-with-trailing-solidus	This error occurs if the parser encounters an end tag[p1201] that has a U+002F (/) code point right before the closing U+003E (>) code point (e.g., `</div/>`). Such a tag is treated as a regular end tag.
eof-before-tag-name	This error occurs if the parser encounters the end of the input stream[p1223] where a tag name is expected. In this case the parser treats the beginning of a start tag[p1200] (i.e., `<`) or an end tag[p1201] (i.e., `</`) as text content.

Code	Description
eof-in-cdata	This error occurs if the parser encounters the end of the input stream[p1223] in a CDATA section[p1209]. The parser treats such CDATA sections as if they are closed immediately before the end of the input stream.
eof-in-comment	This error occurs if the parser encounters the end of the input stream[p1223] in a comment[p1209]. The parser treats such comments as if they are closed immediately before the end of the input stream.
eof-in-doctype	This error occurs if the parser encounters the end of the input stream in a DOCTYPE[p1198]. In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the `Document`[p127] to quirks mode.
eof-in-script-html-comment-like-text	This error occurs if the parser encounters the end of the input stream[p1223] in text that resembles an HTML comment[p1209] inside `script`[p638] element content (e.g., `<script><!-- foo`). Note *Syntactic structures that resemble HTML comments in `script`[p638] elements are parsed as text content. They can be a part of a scripting language-specific syntactic structure or be treated as an HTML-like comment, if the scripting language supports them (e.g., parsing rules for HTML-like comments can be found in Annex B of the JavaScript specification). The common reason for this error is a violation of the restrictions for contents of `script` elements[p651]. [JAVASCRIPT][p1414]*
eof-in-tag	This error occurs if the parser encounters the end of the input stream[p1223] in a start tag[p1200] or an end tag[p1201] (e.g., `<div id=`). Such a tag is ignored.
incorrectly-closed-comment	This error occurs if the parser encounters a comment[p1209] that is closed by the "`--!>`" code point sequence. The parser treats such comments as if they are correctly closed by the "`-->`" code point sequence.
incorrectly-opened-comment	This error occurs if the parser encounters the "`<!`" code point sequence that is not immediately followed by two U+002D (-) code points and that is not the start of a DOCTYPE[p1198] or a CDATA section[p1209]. All content that follows the "`<!`" code point sequence up to a U+003E (>) code point (if present) or to the end of the input stream[p1223] is treated as a comment. Note *One possible cause of this error is using an XML markup declaration (e.g., `<!ELEMENT br EMPTY>`) in HTML.*
invalid-character-sequence-after-doctype-name	This error occurs if the parser encounters any code point sequence other than "`PUBLIC`" and "`SYSTEM`" keywords after a DOCTYPE[p1198] name. In such a case, the parser ignores any following public or system identifiers, and if the DOCTYPE is correctly placed as a document preamble, and if the parser cannot change the mode flag[p1263] is false, sets the `Document`[p127] to quirks mode.

invalid-first-character-of-tag-name	This error occurs if the parser encounters a code point that is not an ASCII alpha where first code point of a start tag[p1200] name or an end tag[p1201] name is expected. If a start tag was expected such code point and a preceding U+003C (<) is treated as text content, and all content that follows is treated as markup. Whereas, if an end tag was expected, such code point and all content that follows up to a U+003E (>) code point (if present) or to the end of the input stream[p1223] is treated as a comment.
	
	Example
	For example, consider the following markup:
	`<42></42>`
	This will be parsed into:
	└ html[p167]
	  ├ head[p168]
	  └ body[p199]
	  ├ #text: *<42>*
	  └ #comment: *42*
	
	Note
	While the first code point of a tag name is limited to an ASCII alpha, a wide range of code points (including ASCII digits) is allowed in subsequent positions.

missing-attribute-value	This error occurs if the parser encounters a U+003E (>) code point where an attribute[p1201] value is expected (e.g., `<div id=>`). The parser treats the attribute as having an empty value.
missing-doctype-name	This error occurs if the parser encounters a DOCTYPE[p1198] that is missing a name (e.g., `<!DOCTYPE>`). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the `Document`[p127] to quirks mode.
missing-doctype-public-identifier	This error occurs if the parser encounters a U+003E (>) code point where start of the DOCTYPE[p1198] public identifier is expected (e.g., `<!DOCTYPE html PUBLIC >`). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the `Document`[p127] to quirks mode.

Code	Description
missing-doctype-system-identifier	This error occurs if the parser encounters a U+003E (>) code point where start of the DOCTYPE[p1198] system identifier is expected (e.g., `<!DOCTYPE html SYSTEM >`). In such a case, if the DOCTYPE is correctly placed as a document preamble, the parser sets the `Document`[p127] to quirks mode.
missing-end-tag-name	This error occurs if the parser encounters a U+003E (>) code point where an end tag[p1201] name is expected, i.e., `</>`. The parser ignores the whole "`</>`" code point sequence.
missing-quote-before-doctype-public-identifier	This error occurs if the parser encounters the DOCTYPE[p1198] public identifier that is not preceded by a quote (e.g., `<!DOCTYPE html PUBLIC -//W3C//DTD HTML 4.01//EN">`). In such a case, the parser ignores the public identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the `Document`[p127] to quirks mode.
missing-quote-before-doctype-system-identifier	This error occurs if the parser encounters the DOCTYPE[p1198] system identifier that is not preceded by a quote (e.g., `<!DOCTYPE html SYSTEM http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">`). In such a case, the parser ignores the system identifier, and if the DOCTYPE is correctly placed as a document preamble, sets the `Document`[p127] to quirks mode.
missing-semicolon-after-character-reference	This error occurs if the parser encounters a character reference[p1208] that is not terminated by a U+003B (;) code point. Usually the parser behaves as if character reference is terminated by the U+003B (;) code point; however, there are some ambiguous cases in which the parser includes subsequent code points in the character reference. Example For example, `¬in` will be parsed as "`¬in`" whereas `&notin` will be parsed as "`∉`".
missing-whitespace-after-doctype-public-keyword	This error occurs if the parser encounters a DOCTYPE[p1198] whose "`PUBLIC`" keyword and public identifier are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present.
missing-whitespace-after-doctype-system-keyword	This error occurs if the parser encounters a DOCTYPE[p1198] whose "`SYSTEM`" keyword and system identifier are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present.
missing-whitespace-before-doctype-name	This error occurs if the parser encounters a DOCTYPE[p1198] whose "`DOCTYPE`" keyword and name are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present.
missing-whitespace-between-attributes	This error occurs if the parser encounters attributes[p1201] that are not separated by ASCII whitespace (e.g., `<div id="foo"class="bar">`). In this case the parser behaves as if ASCII whitespace is present.
missing-whitespace-between-doctype-public-and-system-identifiers	This error occurs if the parser encounters a DOCTYPE[p1198] whose public and system identifiers are not separated by ASCII whitespace. In this case the parser behaves as if ASCII whitespace is present.
nested-comment	This error occurs if the parser encounters a nested comment[p1209] (e.g., `<!-- <!-- nested --> -->`). Such a comment will be closed by the first occurring "`-->`" code point sequence and everything that follows will be treated as markup.
noncharacter-character-reference	This error occurs if the parser encounters a numeric character reference[p1208] that references a noncharacter. The parser resolves such character references as-is.
noncharacter-in-input-stream	This error occurs if the input stream[p1223] contains a noncharacter. Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM.

non-void-html-element-start-tag-with-trailing-solidus	This error occurs if the parser encounters a start tag[p1200] for an element that is not in the list of void elements[p1199] or is not a part of foreign content (i.e., not an SVG or MathML element) that has a U+002F (/) code point right before the closing U+003E (>) code point. The parser behaves as if the U+002F (/) is not present.
	Example
	For example, consider the following markup:
	`<div/><span></span><span></span>`
	This will be parsed into:
	└ **html**[p167]
	  ├ **head**[p168]
	  └ **body**[p199]
	  └ **div**[p251]

Code	Description
	``` ├span[p293] └span[p293] ``` Note *The trailing U+002F (/) in a start tag name can be used only in foreign content to specify self-closing tags. (Self-closing tags don't exist in HTML.) It is also allowed for void elements, but doesn't have any effect in this case.*
null-character-reference	This error occurs if the parser encounters a numeric character reference[p1208] that references a U+0000 NULL code point. The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER.
surrogate-character-reference	This error occurs if the parser encounters a numeric character reference[p1208] that references a surrogate. The parser resolves such character references to a U+FFFD REPLACEMENT CHARACTER.
surrogate-in-input-stream	This error occurs if the input stream[p1223] contains a surrogate. Such code points are parsed as-is and usually, where parsing rules don't apply any additional restrictions, make their way into the DOM. Note *Surrogates can only find their way into the input stream via script APIs such as* `document.write()`[p1099].
unexpected-character-after-doctype-system-identifier	This error occurs if the parser encounters any code points other than ASCII whitespace or closing U+003E (>) after the DOCTYPE[p1198] system identifier. The parser ignores these code points.

unexpected-character-in-attribute-name	This error occurs if the parser encounters a U+0022 (”), U+0027 (’), or U+003C (<) code point in an attribute name[p1201]. The parser includes such code points in the attribute name.
	Note
	Code points that trigger this error are usually a part of another syntactic construct and can be a sign of a typo around the attribute name.
	Example
	For example, consider the following markup:
	`<div foo<div>`
	Due to a forgotten U+003E (>) code point after `foo` the parser treats this markup as a single `div`[p251] element with a "`foo<div`" attribute.
	As another example of this error, consider the following markup:
	`<div id'bar'>`
	Due to a forgotten U+003D (=) code point between an attribute name and value the parser treats this markup as a `div`[p251] element with the attribute "`id'bar'`" that has an empty value.

unexpected-character-in-unquoted-attribute-value	This error occurs if the parser encounters a U+0022 (”), U+0027 (’), U+003C (<), U+003D (=), or U+0060 (`) code point in an unquoted attribute value[p1201]. The parser includes such code points in the attribute value. Note *Code points that trigger this error are usually a part of another syntactic construct and can be a sign of a typo around the attribute value.* Note *U+0060 (`) is in the list of code points that trigger this error because certain legacy user agents treat it as a quote.* Example For example, consider the following markup: `<div foo=b'ar'>` Due to a misplaced U+0027 (’) code point the parser sets the value of the "`foo`" attribute to "`b'ar'`".

Code	Description
unexpected-equals-sign-before-attribute-name	This error occurs if the parser encounters a U+003D (=) code point before an attribute name. In this case the parser treats U+003D (=) as the first code point of the attribute name. Note *The common reason for this error is a forgotten attribute name.* Example For example, consider the following markup: `<div foo="bar" ="baz">` Due to a forgotten attribute name the parser treats this markup as a div[p251] element with two attributes: a "foo" attribute with a "bar" value and a "="baz"" attribute with an empty value.
unexpected-null-character	This error occurs if the parser encounters a U+0000 NULL code point in the input stream[p1223] in certain positions. In general, such code points are either ignored or, for security reasons, replaced with a U+FFFD REPLACEMENT CHARACTER.

unexpected-question-mark-instead-of-tag-name	This error occurs if the parser encounters a U+003F (?) code point where first code point of a start tag[p1200] name is expected. The U+003F (?) and all content that follows up to a U+003E (>) code point (if present) or to the end of the input stream[p1223] is treated as a comment.
	
	Example
	For example, consider the following markup:
	
	`<?xml-stylesheet type="text/css" href="style.css"?>`
	
	This will be parsed into:
	
	├ #comment: *?xml-stylesheet type="text/css" href="style.css"?*
	└ html[p167]
	  ├ head[p168]
	  └ body[p199]
	
	Note
	The common reason for this error is an XML processing instruction (e.g., `<?xml-stylesheet type="text/css" href="style.css"?>`) or an XML declaration (e.g., `<?xml version="1.0" encoding="UTF-8"?>`) being used in HTML.

unexpected-solidus-in-tag	This error occurs if the parser encounters a U+002F (/) code point that is not a part of a quoted attribute[p1201] value and not immediately followed by a U+003E (>) code point in a tag (e.g., `<div / id="foo">`). In this case the parser behaves as if it encountered ASCII whitespace.
unknown-named-character-reference	This error occurs if the parser encounters an ambiguous ampersand[p1209]. In this case the parser doesn't resolve the character reference[p1208].

13.2.3 The input byte stream §[p1216]

The stream of code points that comprises the input to the tokenization stage will be initially seen by the user agent as a stream of bytes (typically coming over the network or from the local file system). The bytes encode the actual characters according to a particular *character encoding*, which the user agent uses to decode the bytes into characters.

Note

For XML documents, the algorithm user agents are required to use to determine the character encoding is given by XML. *This section does not apply to XML documents. [XML][p1419]*

Usually, the encoding sniffing algorithm[p1217] defined below is used to determine the character encoding.

Given a character encoding, the bytes in the input byte stream[p1216] must be converted to characters for the tokenizer's input stream[p1223], by passing the input byte stream[p1216] and character encoding to decode.

Note

A leading Byte Order Mark (BOM) causes the character encoding argument to be ignored and will itself be skipped.

Note

Bytes or sequences of bytes in the original byte stream that did not conform to the Encoding standard (e.g. invalid UTF-8 byte sequences in a UTF-8 input byte stream) are errors that conformance checkers are expected to report. [ENCODING][p1413]

⚠Warning!

The decoder algorithms describe how to handle invalid input; for security reasons, it is imperative that those rules be followed precisely. Differences in how invalid byte sequences are handled can result in, amongst other problems, script injection vulnerabilities ("XSS").

When the HTML parser is decoding an input byte stream, it uses a character encoding and a **confidence**. The confidence is either *tentative*, *certain*, or *irrelevant*. The encoding used, and whether the confidence in that encoding is *tentative* or *certain*, is used during the parsing[p1267] to determine whether to change the encoding[p1223]. If no encoding is necessary, e.g. because the parser is operating on a Unicode stream and doesn't have to use a character encoding at all, then the confidence[p1217] is *irrelevant*.

Note

Some algorithms feed the parser by directly adding characters to the input stream[p1223] rather than adding bytes to the input byte stream[p1216].

13.2.3.1 Parsing with a known character encoding §[p1217]

When the HTML parser is to operate on an input byte stream that has **a known definite encoding**, then the character encoding is that encoding and the confidence[p1217] is *certain*.

13.2.3.2 Determining the character encoding §[p1217]

In some cases, it might be impractical to unambiguously determine the encoding before parsing the document. Because of this, this specification provides for a two-pass mechanism with an optional pre-scan. Implementations are allowed, as described below, to apply a simplified parsing algorithm to whatever bytes they have available before beginning to parse the document. Then, the real parser is started, using a tentative encoding derived from this pre-parse and other out-of-band metadata. If, while the document is being loaded, the user agent discovers a character encoding declaration that conflicts with this information, then the parser can get reinvoked to perform a parse of the document with the real encoding.

User agents must use the following algorithm, called the **encoding sniffing algorithm**, to determine the character encoding to use when decoding a document in the first pass. This algorithm takes as input any out-of-band metadata available to the user agent (e.g. the Content-Type metadata[p96] of the document) and all the bytes available so far, and returns a character encoding and a confidence[p1217] that is either *tentative* or *certain*.

1. If the result of BOM sniffing is an encoding, return that encoding with confidence[p1217] *certain*.

   Note

   Although the decode algorithm will itself change the encoding to use based on the presence of a byte order mark, this algorithm sniffs the BOM as well in order to set the correct document's character encoding and confidence[p1217].

2. If the user has explicitly instructed the user agent to override the document's character encoding with a specific encoding, optionally return that encoding with the confidence[p1217] *certain*.

   Note

   Typically, user agents remember such user requests across sessions, and in some cases apply them to documents in `iframe`[p383]s as well.

3. The user agent may wait for more bytes of the resource to be available, either in this step or at any later step in this algorithm. For instance, a user agent might wait 500ms or 1024 bytes, whichever came first. In general preparsing the source to find the encoding improves performance, as it reduces the need to throw away the data structures used when parsing upon finding the encoding information. However, if the user agent delays too long to obtain data to determine the encoding, then the cost of the delay could outweigh any performance improvements from the preparse.

Note

The authoring conformance requirements for character encoding declarations limit them to only appearing in the first 1024 bytes[p194]. User agents are therefore encouraged to use the prescan algorithm below (as invoked by these steps) on the first 1024 bytes, but not to stall beyond that.

4. If the transport layer specifies a character encoding, and it is supported, return that encoding with the confidence[p1217] *certain*.

5. Optionally prescan the byte stream to determine its encoding[p1219], with the *end condition*[p1219] being when the user agent decides that scanning further bytes would not be efficient. User agents are encouraged to only prescan the first 1024 bytes. User agents may decide that scanning *any* bytes is not efficient, in which case these substeps are entirely skipped.

   The aforementioned algorithm returns either a character encoding or failure. If it returns a character encoding, then return the same encoding, with confidence[p1217] *tentative*.

6. If the HTML parser[p1210] for which this algorithm is being run is associated with a `Document`[p127] *d* whose container document[p955] is non-null, then:

   1. Let *parentDocument* be *d*'s container document[p955].

   2. If *parentDocument*'s origin is same origin[p870] with *d*'s origin and *parentDocument*'s character encoding is not UTF-16BE/LE, then return *parentDocument*'s character encoding, with the confidence[p1217] *tentative*.

7. Otherwise, if the user agent has information on the likely encoding for this page, e.g. based on the encoding of the page when it was last visited, then return that encoding, with the confidence[p1217] *tentative*.

8. The user agent may attempt to autodetect the character encoding from applying frequency analysis or other algorithms to the data stream. Such algorithms may use information about the resource other than the resource's contents, including the address of the resource. If autodetection succeeds in determining a character encoding, and that encoding is a supported encoding, then return that encoding, with the confidence[p1217] *tentative*. [UNIVCHARDET][p1417]

Note

User agents are generally discouraged from attempting to autodetect encodings for resources obtained over the network, since doing so involves inherently non-interoperable heuristics. Attempting to detect encodings based on an HTML document's preamble is especially tricky since HTML markup typically uses only ASCII characters, and HTML documents tend to begin with a lot of markup rather than with text content.

Note

The UTF-8 encoding has a highly detectable bit pattern. Files from the local file system that contain bytes with values greater than 0x7F which match the UTF-8 pattern are very likely to be UTF-8, while documents with byte sequences that do not match it are very likely not. When a user agent can examine the whole file, rather than just the preamble, detecting for UTF-8 specifically can be especially effective. [PPUTF8][p1415] [UTF8DET][p1417]

9. Otherwise, return an implementation-defined or user-specified default character encoding, with the confidence[p1217] *tentative*.

   In controlled environments or in environments where the encoding of documents can be prescribed (for example, for user agents intended for dedicated use in new networks), the comprehensive `UTF-8` encoding is suggested.

   In other environments, the default encoding is typically dependent on the user's locale (an approximation of the languages, and thus often encodings, of the pages that the user is likely to frequent). The following table gives suggested defaults based on the user's locale, for compatibility with legacy content. Locales are identified by BCP 47 language tags. [BCP47][p1410] [ENCODING][p1413]

Locale language		Suggested default encoding
ar	Arabic	windows-1256
az	Azeri	windows-1254
ba	Bashkir	windows-1251
be	Belarusian	windows-1251
bg	Bulgarian	windows-1251
cs	Czech	windows-1250
el	Greek	ISO-8859-7
et	Estonian	windows-1257
fa	Persian	windows-1256
he	Hebrew	windows-1255

Locale language		Suggested default encoding
hr	Croatian	windows-1250
hu	Hungarian	ISO-8859-2
ja	Japanese	Shift_JIS
kk	Kazakh	windows-1251
ko	Korean	EUC-KR
ku	Kurdish	windows-1254
ky	Kyrgyz	windows-1251
lt	Lithuanian	windows-1257
lv	Latvian	windows-1257
mk	Macedonian	windows-1251
pl	Polish	ISO-8859-2
ru	Russian	windows-1251
sah	Yakut	windows-1251
sk	Slovak	windows-1250
sl	Slovenian	ISO-8859-2
sr	Serbian	windows-1251
tg	Tajik	windows-1251
th	Thai	windows-874
tr	Turkish	windows-1254
tt	Tatar	windows-1251
uk	Ukrainian	windows-1251
vi	Vietnamese	windows-1258
zh-Hans, zh-CN, zh-SG	Chinese, Simplified	GBK
zh-Hant, zh-HK, zh-MO, zh-TW	Chinese, Traditional	Big5
All other locales		windows-1252

The contents of this table are derived from the intersection of Windows, Chrome, and Firefox defaults.

The document's character encoding must immediately be set to the value returned from this algorithm, at the same time as the user agent uses the returned value to select the decoder to use for the input byte stream.

When an algorithm requires a user agent to **prescan a byte stream to determine its encoding**, given some defined ***end condition***, then it must run the following steps. If at any point during these steps (including during instances of the get an attribute[p1221] algorithm invoked by this one) the user agent either runs out of bytes (meaning the *position* pointer created in the first step below goes beyond the end of the byte stream obtained so far) or reaches its *end condition*, then abort the prescan a byte stream to determine its encoding[p1219] algorithm and return the result get an XML encoding[p1222] applied to the same bytes that the prescan a byte stream to determine its encoding[p1219] algorithm was applied to. Otherwise, these steps will return a character encoding.

1. Let *fallback encoding* be null.
2. Let *position* be a pointer to a byte in the input byte stream, initially pointing at the first byte.
3. Prescan for UTF-16 XML declarations: If *position* points to:

   ↪ **A sequence of bytes starting with: 0x3C, 0x0, 0x3F, 0x0, 0x78, 0x0 (case-sensitive UTF-16 little-endian '<?x')**

   Return UTF-16LE.

   ↪ **A sequence of bytes starting with: 0x0, 0x3C, 0x0, 0x3F, 0x0, 0x78 (case-sensitive UTF-16 big-endian '<?x')**

   Return UTF-16BE.

   Note

   For historical reasons, the prefix is two bytes longer than in Appendix F of XML and the encoding name is not checked.

4. *Loop*: If *position* points to:

   ↪ **A sequence of bytes starting with: 0x3C 0x21 0x2D 0x2D (`<!--`)**

   Advance the *position* pointer so that it points at the first 0x3E byte which is preceded by two 0x2D bytes (i.e. at the end of an ASCII '-->' sequence) and comes after the 0x3C byte that was found. (The two 0x2D bytes can be the same

as those in the '<!--' sequence.)

↪ **A sequence of bytes starting with: 0x3C, 0x4D or 0x6D, 0x45 or 0x65, 0x54 or 0x74, 0x41 or 0x61, and one of 0x09, 0x0A, 0x0C, 0x0D, 0x20, 0x2F (case-insensitive ASCII '<meta' followed by a space or slash)**

1. Advance the *position* pointer so that it points at the next 0x09, 0x0A, 0x0C, 0x0D, 0x20, or 0x2F byte (the one in sequence of characters matched above).
2. Let *attribute list* be an empty list of strings.
3. Let *got pragma* be false.
4. Let *need pragma* be null.
5. Let *charset* be the null value (which, for the purposes of this algorithm, is distinct from an unrecognized encoding or the empty string).
6. *Attributes*: Get an attribute[p1221] and its value. If no attribute was sniffed, then jump to the *processing* step below.
7. If the attribute's name is already in *attribute list*, then return to the step labeled *attributes*.
8. Add the attribute's name to *attribute list*.
9. Run the appropriate step from the following list, if one applies:

   ↪ **If the attribute's name is "`http-equiv`"**
   If the attribute's value is "`content-type`", then set *got pragma* to true.

   ↪ **If the attribute's name is "`content`"**
   Apply the algorithm for extracting a character encoding from a `meta` element[p96], giving the attribute's value as the string to parse. If a character encoding is returned, and if *charset* is still set to null, let *charset* be the encoding returned, and set *need pragma* to true.

   ↪ **If the attribute's name is "`charset`"**
   Let *charset* be the result of getting an encoding from the attribute's value, and set *need pragma* to false.

10. Return to the step labeled *attributes*.
11. *Processing*: If *need pragma* is null, then jump to the step below labeled *next byte*.
12. If *need pragma* is true but *got pragma* is false, then jump to the step below labeled *next byte*.
13. If *charset* is failure, then jump to the step below labeled *next byte*.
14. If *charset* is UTF-16BE/LE, then set *charset* to UTF-8.
15. If *charset* is x-user-defined, then set *charset* to windows-1252.
16. Return *charset*.

↪ **A sequence of bytes starting with a 0x3C byte (<), optionally a 0x2F byte (/), and finally a byte in the range 0x41-0x5A or 0x61-0x7A (A-Z or a-z)**

1. Advance the *position* pointer so that it points at the next 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x3E (>) byte.
2. Repeatedly get an attribute[p1221] until no further attributes can be found, then jump to the step below labeled *next byte*.

↪ **A sequence of bytes starting with: 0x3C 0x21 (`<!`)**
↪ **A sequence of bytes starting with: 0x3C 0x2F (`</`)**
↪ **A sequence of bytes starting with: 0x3C 0x3F (`<?`)**
Advance the *position* pointer so that it points at the first 0x3E byte (>) that comes after the 0x3C byte that was found.

↪ **Any other byte**
Do nothing with that byte.

5. *Next byte*: Move *position* so it points at the next byte in the input byte stream, and return to the step above labeled *loop*.

When the prescan a byte stream to determine its encoding[p1219] algorithm says to **get an attribute**, it means doing this:

1. If the byte at *position* is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x2F (/) then advance *position* to the next byte and redo this step.
2. If the byte at *position* is 0x3E (>), then abort the get an attribute[p1221] algorithm. There isn't one.
3. Otherwise, the byte at *position* is the start of the attribute name. Let *attribute name* and *attribute value* be the empty string.
4. Process the byte at *position* as follows:

   ↪ **If it is 0x3D (=), and the *attribute name* is longer than the empty string**
   Advance *position* to the next byte and jump to the step below labeled *value*.

   ↪ **If it is 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP)**
   Jump to the step below labeled *spaces*.

   ↪ **If it is 0x2F (/) or 0x3E (>)**
   Abort the get an attribute[p1221] algorithm. The attribute's name is the value of *attribute name*, its value is the empty string.

   ↪ **If it is in the range 0x41 (A) to 0x5A (Z)**
   Append the code point *b*+0x20 to *attribute name* (where *b* is the value of the byte at *position*). (This converts the input to lowercase.)

   ↪ **Anything else**
   Append the code point with the same value as the byte at *position* to *attribute name*. (It doesn't actually matter how bytes outside the ASCII range are handled here, since only ASCII bytes can contribute to the detection of a character encoding.)
5. Advance *position* to the next byte and return to the previous step.
6. *Spaces*: If the byte at *position* is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) then advance *position* to the next byte, then, repeat this step.
7. If the byte at *position* is *not* 0x3D (=), abort the get an attribute[p1221] algorithm. The attribute's name is the value of *attribute name*, its value is the empty string.
8. Advance *position* past the 0x3D (=) byte.
9. *Value*: If the byte at *position* is one of 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), or 0x20 (SP) then advance *position* to the next byte, then, repeat this step.
10. Process the byte at *position* as follows:

    ↪ **If it is 0x22 (") or 0x27 (')**

    1. Let *b* be the value of the byte at *position*.
    2. *Quote loop*: Advance *position* to the next byte.
    3. If the value of the byte at *position* is the value of *b*, then advance *position* to the next byte and abort the "get an attribute" algorithm. The attribute's name is the value of *attribute name*, and its value is the value of *attribute value*.
    4. Otherwise, if the value of the byte at *position* is in the range 0x41 (A) to 0x5A (Z), then append a code point to *attribute value* whose value is 0x20 more than the value of the byte at *position*.
    5. Otherwise, append a code point to *attribute value* whose value is the same as the value of the byte at *position*.
    6. Return to the step above labeled *quote loop*.

    ↪ **If it is 0x3E (>)**
    Abort the get an attribute[p1221] algorithm. The attribute's name is the value of *attribute name*, its value is the empty string.

↪ **If it is in the range 0x41 (A) to 0x5A (Z)**

Append a code point *b*+0x20 to *attribute value* (where *b* is the value of the byte at *position*). Advance *position* to the next byte.

↪ **Anything else**

Append a code point with the same value as the byte at *position* to *attribute value*. Advance *position* to the next byte.

11. Process the byte at *position* as follows:

↪ **If it is 0x09 (HT), 0x0A (LF), 0x0C (FF), 0x0D (CR), 0x20 (SP), or 0x3E (>)**

Abort the get an attribute[p1221] algorithm. The attribute's name is the value of *attribute name* and its value is the value of *attribute value*.

↪ **If it is in the range 0x41 (A) to 0x5A (Z)**

Append a code point *b*+0x20 to *attribute value* (where *b* is the value of the byte at *position*).

↪ **Anything else**

Append a code point with the same value as the byte at *position* to *attribute value*.

12. Advance *position* to the next byte and return to the previous step.

When the prescan a byte stream to determine its encoding[p1219] algorithm is aborted without returning an encoding, **get an XML encoding** means doing this.

Note

Looking for syntax resembling an XML declaration, even in `text/html`[p1380]*, is necessary for compatibility with existing content.*

1. Let *encodingPosition* be a pointer to the start of the stream.
2. If *encodingPosition* does not point to the start of a byte sequence 0x3C, 0x3F, 0x78, 0x6D, 0x6C (`<?xml`), then return failure.
3. Let *xmlDeclarationEnd* be a pointer to the next byte in the input byte stream which is 0x3E (>). If there is no such byte, then return failure.
4. Set *encodingPosition* to the position of the first occurrence of the subsequence of bytes 0x65, 0x6E, 0x63, 0x6F, 0x64, 0x69, 0x6E, 0x67 (`encoding`) at or after the current *encodingPosition*. If there is no such sequence, then return failure.
5. Advance *encodingPosition* past the 0x67 (g) byte.
6. While the byte at *encodingPosition* is less than or equal to 0x20 (i.e., it is either an ASCII space or control character), advance *encodingPosition* to the next byte.
7. If the byte at *encodingPosition* is not 0x3D (=), then return failure.
8. Advance *encodingPosition* to the next byte.
9. While the byte at *encodingPosition* is less than or equal to 0x20 (i.e., it is either an ASCII space or control character), advance *encodingPosition* to the next byte.
10. Let *quoteMark* be the byte at *encodingPosition*.
11. If *quoteMark* is not either 0x22 (") or 0x27 ('), then return failure.
12. Advance *encodingPosition* to the next byte.
13. Let *encodingEndPosition* be the position of the next occurrence of *quoteMark* at or after *encodingPosition*. If *quoteMark* does not occur again, then return failure.
14. Let *potentialEncoding* be the sequence of the bytes between *encodingPosition* (inclusive) and *encodingEndPosition* (exclusive).
15. If *potentialEncoding* contains one or more bytes whose byte value is 0x20 or below, then return failure.
16. Let *encoding* be the result of getting an encoding given *potentialEncoding* isomorphic decoded.
17. If the *encoding* is UTF-16BE/LE, then change it to UTF-8.
18. Return *encoding*.

For the sake of interoperability, user agents should not use a pre-scan algorithm that returns different results than the one described above. (But, if you do, please at least let us know, so that we can improve this algorithm and benefit everyone...)

13.2.3.3 Character encodings §[p1223]

User agents must support the encodings defined in *Encoding*, including, but not limited to, **UTF-8**, **ISO-8859-2**, **ISO-8859-7**, **ISO-8859-8**, **windows-874**, **windows-1250**, **windows-1251**, **windows-1252**, **windows-1254**, **windows-1255**, **windows-1256**, **windows-1257**, **windows-1258**, **GBK**, **Big5**, **ISO-2022-JP**, **Shift_JIS**, **EUC-KR**, **UTF-16BE**, **UTF-16LE**, **UTF-16BE/LE**, and **x-user-defined**. User agents must not support other encodings.

Note

The above prohibits supporting, for example, CESU-8, UTF-7, BOCU-1, SCSU, EBCDIC, and UTF-32. This specification does not make any attempt to support prohibited encodings in its algorithms; support and use of prohibited encodings would thus lead to unexpected behavior. [CESU8][p1410] [UTF7][p1417] [BOCU1][p1410] [SCSU][p1417]

13.2.3.4 Changing the encoding while parsing §[p1223]

When the parser requires the user agent to **change the encoding**, it must run the following steps. This might happen if the encoding sniffing algorithm[p1217] described above failed to find a character encoding, or if it found a character encoding that was not the actual encoding of the file.

1. If the encoding that is already being used to interpret the input stream is UTF-16BE/LE, then set the confidence[p1217] to *certain* and return. The new encoding is ignored; if it was anything but the same encoding, then it would be clearly incorrect.
2. If the new encoding is UTF-16BE/LE, then change it to UTF-8.
3. If the new encoding is x-user-defined, then change it to windows-1252.
4. If the new encoding is identical or equivalent to the encoding that is already being used to interpret the input stream, then set the confidence[p1217] to *certain* and return. This happens when the encoding information found in the file matches what the encoding sniffing algorithm[p1217] determined to be the encoding, and in the second pass through the parser if the first pass found that the encoding sniffing algorithm described in the earlier section failed to find the right encoding.
5. If all the bytes up to the last byte converted by the current decoder have the same Unicode interpretations in both the current encoding and the new encoding, and if the user agent supports changing the converter on the fly, then the user agent may change to the new converter for the encoding on the fly. Set the document's character encoding and the encoding used to convert the input stream to the new encoding, set the confidence[p1217] to *certain*, and return.
6. Otherwise, restart the navigate[p977] algorithm, with *historyHandling*[p977] set to "`replace`[p976]" and other inputs kept the same, but this time skip the encoding sniffing algorithm[p1217] and instead just set the encoding to the new encoding and the confidence[p1217] to *certain*. Whenever possible, this should be done without actually contacting the network layer (the bytes should be re-parsed from memory), even if, e.g., the document is marked as not being cacheable. If this is not possible and contacting the network layer would involve repeating a request that uses a method other than `GET`, then instead set the confidence[p1217] to *certain* and ignore the new encoding. The resource will be misinterpreted. User agents may notify the user of the situation, to aid in application development.

Note

This algorithm is only invoked when a new encoding is found declared on a `meta`[p184] element.

13.2.3.5 Preprocessing the input stream §[p1223]

The **input stream** consists of the characters pushed into it as the input byte stream[p1216] is decoded or from the various APIs that directly manipulate the input stream.

Any occurrences of surrogates are surrogate-in-input-stream[p1215] parse errors[p1212]. Any occurrences of noncharacters are noncharacter-in-input-stream[p1214] parse errors[p1212] and any occurrences of controls other than ASCII whitespace and U+0000 NULL characters are control-character-in-input-stream[p1212] parse errors[p1212].

Note

The handling of U+0000 NULL characters varies based on where the characters are found and happens at the later stages of the parsing. They are either ignored or, for security reasons, replaced with a U+FFFD REPLACEMENT CHARACTER. This handling is, by necessity, spread across both the tokenization stage and the tree construction stage.

Before the tokenization[p1229] stage, the input stream must be preprocessed by normalizing newlines. Thus, newlines in HTML DOMs are represented by U+000A LF characters, and there are never any U+000D CR characters in the input to the tokenization[p1229] stage.

The **next input character** is the first character in the input stream[p1223] that has not yet been **consumed** or explicitly ignored by the requirements in this section. Initially, the *next input character*[p1224] is the first character in the input. The **current input character** is the last character to have been *consumed*.

The **insertion point** is the position (just before a character or just before the end of the input stream) where content inserted using `document.write()`[p1099] is actually inserted. The insertion point is relative to the position of the character immediately after it, it is not an absolute offset into the input stream. Initially, the insertion point is undefined.

The "EOF" character in the tables below is a conceptual character representing the end of the input stream[p1223]. If the parser is a script-created parser[p1097], then the end of the input stream[p1223] is reached when an **explicit "EOF" character** (inserted by the `document.close()`[p1098] method) is consumed. Otherwise, the "EOF" character is not a real character in the stream, but rather the lack of any further characters.

13.2.4 Parse state §[p1224]

13.2.4.1 The insertion mode §[p1224]

The **insertion mode** is a state variable that controls the primary operation of the tree construction stage.

Initially, the insertion mode[p1224] is "initial[p1263]". It can change to "before html[p1265]", "before head[p1266]", "in head[p1266]", "in head noscript[p1268]", "after head[p1269]", "in body[p1270]", "text[p1280]", "in table[p1281]", "in table text[p1283]", "in caption[p1284]", "in column group[p1284]", "in table body[p1285]", "in row[p1286]", "in cell[p1287]", "in select[p1288]", "in select in table[p1290]", "in template[p1290]", "after body[p1291]", "in frameset[p1292]", "after frameset[p1293]", "after after body[p1293]", and "after after frameset[p1293]" during the course of the parsing, as described in the tree construction[p1257] stage. The insertion mode affects how tokens are processed and whether CDATA sections are supported.

Several of these modes, namely "in head[p1266]", "in body[p1270]", "in table[p1281]", and "in select[p1288]", are special, in that the other modes defer to them at various times. When the algorithm below says that the user agent is to do something "**using the rules for** the *m* insertion mode", where *m* is one of these modes, the user agent must use the rules described under the *m* insertion mode[p1224]'s section, but must leave the insertion mode[p1224] unchanged unless the rules in *m* themselves switch the insertion mode[p1224] to a new value.

When the insertion mode is switched to "text[p1280]" or "in table text[p1283]", the **original insertion mode** is also set. This is the insertion mode to which the tree construction stage will return.

Similarly, to parse nested `template`[p656] elements, a **stack of template insertion modes** is used. It is initially empty. The **current template insertion mode** is the insertion mode that was most recently added to the stack of template insertion modes[p1224]. The algorithms in the sections below will *push* insertion modes onto this stack, meaning that the specified insertion mode is to be added to the stack, and *pop* insertion modes from the stack, which means that the most recently added insertion mode must be removed from the stack.

When the steps below require the UA to **reset the insertion mode appropriately**, it means the UA must follow these steps:

1. Let *last* be false.
2. Let *node* be the last node in the stack of open elements[p1225].
3. *Loop*: If *node* is the first node in the stack of open elements, then set *last* to true, and, if the parser was created as part of the HTML fragment parsing algorithm[p1310] (fragment case[p1311]), set *node* to the *context*[p1310] element passed to that algorithm.
4. If *node* is a `select`[p559] element, run these substeps:

1. If *last* is true, jump to the step below labeled *done*.
2. Let *ancestor* be *node*.
3. *Loop*: If *ancestor* is the first node in the stack of open elements[p1225], jump to the step below labeled *done*.
4. Let *ancestor* be the node before *ancestor* in the stack of open elements[p1225].
5. If *ancestor* is a `template`[p656] node, jump to the step below labeled *done*.
6. If *ancestor* is a `table`[p469] node, switch the insertion mode[p1224] to "in select in table[p1290]" and return.
7. Jump back to the step labeled *loop*.
8. *Done*: Switch the insertion mode[p1224] to "in select[p1288]" and return.

5. If *node* is a `td`[p484] or `th`[p486] element and *last* is false, then switch the insertion mode[p1224] to "in cell[p1287]" and return.
6. If *node* is a `tr`[p483] element, then switch the insertion mode[p1224] to "in row[p1286]" and return.
7. If *node* is a `tbody`[p480], `thead`[p481], or `tfoot`[p482] element, then switch the insertion mode[p1224] to "in table body[p1285]" and return.
8. If *node* is a `caption`[p477] element, then switch the insertion mode[p1224] to "in caption[p1284]" and return.
9. If *node* is a `colgroup`[p478] element, then switch the insertion mode[p1224] to "in column group[p1284]" and return.
10. If *node* is a `table`[p469] element, then switch the insertion mode[p1224] to "in table[p1281]" and return.
11. If *node* is a `template`[p656] element, then switch the insertion mode[p1224] to the current template insertion mode[p1224] and return.
12. If *node* is a `head`[p168] element and *last* is false, then switch the insertion mode[p1224] to "in head[p1266]" and return.
13. If *node* is a `body`[p199] element, then switch the insertion mode[p1224] to "in body[p1270]" and return.
14. If *node* is a `frameset`[p1369] element, then switch the insertion mode[p1224] to "in frameset[p1292]" and return. (fragment case[p1311])
15. If *node* is an `html`[p167] element, run these substeps:
    1. If the head element pointer[p1228] is null, switch the insertion mode[p1224] to "before head[p1266]" and return. (fragment case[p1311])
    2. Otherwise, the head element pointer[p1228] is not null, switch the insertion mode[p1224] to "after head[p1269]" and return.
16. If *last* is true, then switch the insertion mode[p1224] to "in body[p1270]" and return. (fragment case[p1311])
17. Let *node* now be the node before *node* in the stack of open elements[p1225].
18. Return to the step labeled *loop*.

13.2.4.2 The stack of open elements §[p1225]

Initially, the **stack of open elements** is empty. The stack grows downwards; the topmost node on the stack is the first one added to the stack, and the bottommost node of the stack is the most recently added node in the stack (notwithstanding when the stack is manipulated in a random access fashion as part of the handling for misnested tags[p1278]).

Note

The "before html[p1265]" insertion mode[p1224] creates the `html`[p167] document element, which is then added to the stack.

Note

In the fragment case[p1311], the stack of open elements[p1225] is initialized to contain an `html`[p167] element that is created as part of that algorithm[p1310]. (The fragment case[p1311] skips the "before html[p1265]" insertion mode[p1224].)

The `html`[p167] node, however it is created, is the topmost node of the stack. It only gets popped off the stack when the parser finishes[p1296].

The **current node** is the bottommost node in this stack of open elements[p1225].

The **adjusted current node** is the *context*[p1310] element if the parser was created as part of the HTML fragment parsing algorithm[p1310] and the stack of open elements[p1225] has only one element in it (fragment case[p1311]); otherwise, the adjusted current node[p1226] is the current node[p1225].

Elements in the stack of open elements[p1225] fall into the following categories:

Special

The following elements have varying levels of special parsing rules: HTML's address[p217], applet[p1362], area[p463], article[p201], aside[p209], base[p170], basefont[p1363], bgsound[p1362], blockquote[p229], body[p199], br[p294], button[p556], caption[p477], center[p1363], col[p479], colgroup[p478], dd[p243], details[p627], dir[p1362], div[p251], dl[p238], dt[p242], embed[p391], fieldset[p584], figcaption[p247], figure[p244], footer[p214], form[p505], frame[p1369], frameset[p1369], h1[p211], h2[p211], h3[p211], h4[p211], h5[p211], h6[p211], head[p168], header[p213], hgroup[p212], hr[p226], html[p167], iframe[p383], img[p338], input[p512], keygen[p1362], li[p236], link[p172], listing[p1362], main[p247], marquee[p1367], menu[p235], meta[p184], nav[p206], noembed[p1362], noframes[p1362], noscript[p654], object[p394], ol[p232], p[p223], param[p1362], plaintext[p1362], pre[p228], script[p638], search[p249], section[p203], select[p559], source[p335], style[p195], summary[p630], table[p469], tbody[p480], td[p484], template[p656], textarea[p570], tfoot[p482], th[p486], thead[p481], title[p169], tr[p483], track[p403], ul[p234], wbr[p295], xmp[p1363]; MathML mi, MathML mo, MathML mn, MathML ms, MathML mtext, and MathML annotation-xml; and SVG foreignObject, SVG desc, and SVG title.

Note

An image *start tag token is handled by the tree builder, but it is not in this list because it is not an element; it gets turned into an* img[p338] *element.*

Formatting

The following HTML elements are those that end up in the list of active formatting elements[p1227]: a[p252], b[p287], big[p1363], code[p281], em[p255], font[p1363], i[p286], nobr[p1363], s[p259], small[p257], strike[p1363], strong[p256], tt[p1363], and u[p288].

Ordinary

All other elements found while parsing an HTML document.

Note

Typically, the special[p1226] elements have the start and end tag tokens handled specifically, while ordinary[p1226] elements' tokens fall into "any other start tag" and "any other end tag" clauses, and some parts of the tree builder check if a particular element in the stack of open elements[p1225] is in the special[p1226] category. However, some elements (e.g., the option[p567] *element) have their start or end tag tokens handled specifically, but are still not in the special[p1226] category, so that they get the ordinary[p1226] handling elsewhere.*

The stack of open elements[p1225] is said to **have an element *target node* in a specific scope** consisting of a list of element types *list* when the following algorithm terminates in a match state:

1. Initialize *node* to be the current node[p1225] (the bottommost node of the stack).
2. If *node* is the target node, terminate in a match state.
3. Otherwise, if *node* is one of the element types in *list*, terminate in a failure state.
4. Otherwise, set *node* to the previous entry in the stack of open elements[p1225] and return to step 2. (This will never fail, since the loop will always terminate in the previous step if the top of the stack — an html[p167] element — is reached.)

The stack of open elements[p1225] is said to **have a particular element in scope** when it has that element in the specific scope[p1226] consisting of the following element types:

- applet[p1362]
- caption[p477]
- html[p167]
- table[p469]
- td[p484]
- th[p486]
- marquee[p1367]
- object[p394]
- template[p656]
- MathML mi
- MathML mo
- MathML mn
- MathML ms
- MathML mtext
- MathML annotation-xml

- SVG foreignObject
- SVG desc
- SVG title

The stack of open elements[p1225] is said to **have a particular element in list item scope** when it has that element in the specific scope[p1226] consisting of the following element types:

- All the element types listed above for the *has an element in scope*[p1226] algorithm.
- ol[p232] in the HTML namespace
- ul[p234] in the HTML namespace

The stack of open elements[p1225] is said to **have a particular element in button scope** when it has that element in the specific scope[p1226] consisting of the following element types:

- All the element types listed above for the *has an element in scope*[p1226] algorithm.
- button[p556] in the HTML namespace

The stack of open elements[p1225] is said to **have a particular element in table scope** when it has that element in the specific scope[p1226] consisting of the following element types:

- html[p167] in the HTML namespace
- table[p469] in the HTML namespace
- template[p656] in the HTML namespace

The stack of open elements[p1225] is said to **have a particular element in select scope** when it has that element in the specific scope[p1226] consisting of all element types *except* the following:

- optgroup[p566] in the HTML namespace
- option[p567] in the HTML namespace

Nothing happens if at any time any of the elements in the stack of open elements[p1225] are moved to a new location in, or removed from, the Document[p127] tree. In particular, the stack is not changed in this situation. This can cause, amongst other strange effects, content to be appended to nodes that are no longer in the DOM.

Note

In some cases (namely, when closing misnested formatting elements[p1278]), the stack is manipulated in a random-access fashion.

13.2.4.3 The list of active formatting elements §[p1227]

Initially, the **list of active formatting elements** is empty. It is used to handle mis-nested formatting element tags[p1226].

The list contains elements in the formatting[p1226] category, and markers[p1227]. The **markers** are inserted when entering applet[p1362], object[p394], marquee[p1367], template[p656], td[p484], th[p486], and caption[p477] elements, and are used to prevent formatting from "leaking" *into* applet[p1362], object[p394], marquee[p1367], template[p656], td[p484], th[p486], and caption[p477] elements.

In addition, each element in the list of active formatting elements[p1227] is associated with the token for which it was created, so that further elements can be created for that token if necessary.

When the steps below require the UA to **push onto the list of active formatting elements** an element *element*, the UA must perform the following steps:

1. If there are already three elements in the list of active formatting elements[p1227] after the last marker[p1227], if any, or anywhere in the list if there are no markers[p1227], that have the same tag name, namespace, and attributes as *element*, then remove the earliest such element from the list of active formatting elements[p1227]. For these purposes, the attributes must be compared as they were when the elements were created by the parser; two elements have the same attributes if all their parsed attributes can be paired such that the two attributes in each pair have identical names, namespaces, and values (the order of the attributes does not matter).

   Note

   This is the Noah's Ark clause. But with three per family instead of two.

2. Add *element* to the list of active formatting elements[p1227].

When the steps below require the UA to **reconstruct the active formatting elements**, the UA must perform the following steps:

1. If there are no entries in the list of active formatting elements[p1227], then there is nothing to reconstruct; stop this algorithm.
2. If the last (most recently added) entry in the list of active formatting elements[p1227] is a marker[p1227], or if it is an element that is in the stack of open elements[p1225], then there is nothing to reconstruct; stop this algorithm.
3. Let *entry* be the last (most recently added) element in the list of active formatting elements[p1227].
4. *Rewind*: If there are no entries before *entry* in the list of active formatting elements[p1227], then jump to the step labeled *create*.
5. Let *entry* be the entry one earlier than *entry* in the list of active formatting elements[p1227].
6. If *entry* is neither a marker[p1227] nor an element that is also in the stack of open elements[p1225], go to the step labeled *rewind*.
7. *Advance*: Let *entry* be the element one later than *entry* in the list of active formatting elements[p1227].
8. *Create*: Insert an HTML element[p1260] for the token for which the element *entry* was created, to obtain *new element*.
9. Replace the entry for *entry* in the list with an entry for *new element*.
10. If the entry for *new element* in the list of active formatting elements[p1227] is not the last entry in the list, return to the step labeled *advance*.

This has the effect of reopening all the formatting elements that were opened in the current body, cell, or caption (whichever is youngest) that haven't been explicitly closed.

Note

The way this specification is written, the list of active formatting elements[p1227] always consists of elements in chronological order with the least recently added element first and the most recently added element last (except for while steps 7 to 10 of the above algorithm are being executed, of course).

When the steps below require the UA to **clear the list of active formatting elements up to the last marker**, the UA must perform the following steps:

1. Let *entry* be the last (most recently added) entry in the list of active formatting elements[p1227].
2. Remove *entry* from the list of active formatting elements[p1227].
3. If *entry* was a marker[p1227], then stop the algorithm at this point. The list has been cleared up to the last marker[p1227].
4. Go to step 1.

13.2.4.4 The element pointers §[p1228]

Initially, the **`head` element pointer** and the **`form` element pointer** are both null.

Once a `head`[p168] element has been parsed (whether implicitly or explicitly) the head element pointer[p1228] gets set to point to this node.

The `form` element pointer[p1228] points to the last `form`[p505] element that was opened and whose end tag has not yet been seen. It is used to make form controls associate with forms in the face of dramatically bad markup, for historical reasons. It is ignored inside `template`[p656] elements.

13.2.4.5 Other parsing state flags §[p1228]

The **scripting flag** is set to "enabled" if scripting was enabled[p1039] for the `Document`[p127] with which the parser is associated when the parser was created, and "disabled" otherwise.

Note

The scripting flag[p1228] can be enabled even when the parser was created as part of the HTML fragment parsing algorithm[p1310], even though `script`[p638] elements don't execute in that case.

The **frameset-ok flag** is set to "ok" when the parser is created. It is set to "not ok" after certain tokens are seen.

13.2.5 Tokenization §p1229

Implementations must act as if they used the following state machine to tokenize HTML. The state machine must start in the data state p1229. Most states consume a single character, which may have various side-effects, and either switches the state machine to a new state to reconsume p1229 the current input character p1224, or switches it to a new state to consume the next character p1224, or stays in the same state to consume the next character. Some states have more complicated behavior and can consume several characters before switching to another state. In some cases, the tokenizer state is also changed by the tree construction stage.

When a state says to **reconsume** a matched character in a specified state, that means to switch to that state, but when it attempts to consume the next input character p1224, provide it with the current input character p1224 instead.

The exact behavior of certain states depends on the insertion mode p1224 and the stack of open elements p1225. Certain states also use a ***temporary buffer*** to track progress, and the character reference state p1254 uses a ***return state*** to return to the state it was invoked from.

The output of the tokenization step is a series of zero or more of the following tokens: DOCTYPE, start tag, end tag, comment, character, end-of-file. DOCTYPE tokens have a name, a public identifier, a system identifier, and a ***force-quirks flag***. When a DOCTYPE token is created, its name, public identifier, and system identifier must be marked as missing (which is a distinct state from the empty string), and the *force-quirks flag* p1229 must be set to *off* (its other state is *on*). Start and end tag tokens have a tag name, a **self-closing flag**, and a list of attributes, each of which has a name and a value. When a start or end tag token is created, its *self-closing flag* p1229 must be unset (its other state is that it be set), and its attributes list must be empty. Comment and character tokens have data.

When a token is emitted, it must immediately be handled by the tree construction p1257 stage. The tree construction stage can affect the state of the tokenization stage, and can insert additional characters into the stream. (For example, the `script` p638 element can result in scripts executing and using the dynamic markup insertion p1096 APIs to insert characters into the stream being tokenized.)

Note

Creating a token and emitting it are distinct actions. It is possible for a token to be created but implicitly abandoned (never emitted), e.g. if the file ends unexpectedly while processing the characters that are being parsed into a start tag token.

When a start tag token is emitted with its *self-closing flag* p1229 set, if the flag is not **acknowledged** when it is processed by the tree construction stage, that is a non-void-html-element-start-tag-with-trailing-solidus p1214 parse error p1212.

When an end tag token is emitted with attributes, that is an end-tag-with-attributes p1212 parse error p1212.

When an end tag token is emitted with its *self-closing flag* p1229 set, that is an end-tag-with-trailing-solidus p1212 parse error p1212.

An **appropriate end tag token** is an end tag token whose tag name matches the tag name of the last start tag to have been emitted from this tokenizer, if any. If no start tag has been emitted from this tokenizer, then no end tag token is appropriate.

A character reference p1208 is said to be **consumed as part of an attribute** if the *return state* p1229 is either attribute value (double-quoted) state p1241, attribute value (single-quoted) state p1241 or attribute value (unquoted) state p1242.

When a state says to **flush code points consumed as a character reference**, it means that for each code point in the *temporary buffer* p1229 (in the order they were added to the buffer) user agent must append the code point from the buffer to the current attribute's value if the character reference was consumed as part of an attribute p1229, or emit the code point as a character token otherwise.

Before each step of the tokenizer, the user agent must first check the parser pause flag p1212. If it is true, then the tokenizer must abort the processing of any nested invocations of the tokenizer, yielding control back to the caller.

The tokenizer state machine consists of the states defined in the following subsections.

13.2.5.1 Data state §p1229

Consume the next input character p1224:

↪ **U+0026 AMPERSAND (&)**

Set the *return state* p1229 to the data state p1229. Switch to the character reference state p1254.

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the tag open state[p1231].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Emit the current input character[p1224] as a character token.

↪ **EOF**

Emit an end-of-file token.

↪ **Anything else**

Emit the current input character[p1224] as a character token.

13.2.5.2 RCDATA state §[p1230]

Consume the next input character[p1224]:

↪ **U+0026 AMPERSAND (&)**

Set the *return state*[p1229] to the RCDATA state[p1230]. Switch to the character reference state[p1254].

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the RCDATA less-than sign state[p1232].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

Emit an end-of-file token.

↪ **Anything else**

Emit the current input character[p1224] as a character token.

13.2.5.3 RAWTEXT state §[p1230]

Consume the next input character[p1224]:

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the RAWTEXT less-than sign state[p1233].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

Emit an end-of-file token.

↪ **Anything else**

Emit the current input character[p1224] as a character token.

13.2.5.4 Script data state §[p1230]

Consume the next input character[p1224]:

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the script data less-than sign state[p1234].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

Emit an end-of-file token.

↪ **Anything else**

Emit the current input character[p1224] as a character token.

13.2.5.5 PLAINTEXT state §[p1231]

Consume the next input character[p1224]:

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

Emit an end-of-file token.

↪ **Anything else**

Emit the current input character[p1224] as a character token.

13.2.5.6 Tag open state §[p1231]

Consume the next input character[p1224]:

↪ **U+0021 EXCLAMATION MARK (!)**

Switch to the markup declaration open state[p1243].

↪ **U+002F SOLIDUS (/)**

Switch to the end tag open state[p1231].

↪ **ASCII alpha**

Create a new start tag token, set its tag name to the empty string. Reconsume[p1229] in the tag name state[p1232].

↪ **U+003F QUESTION MARK (?)**

This is an unexpected-question-mark-instead-of-tag-name[p1216] parse error[p1212]. Create a comment token whose data is the empty string. Reconsume[p1229] in the bogus comment state[p1243].

↪ **EOF**

This is an eof-before-tag-name[p1212] parse error[p1212]. Emit a U+003C LESS-THAN SIGN character token and an end-of-file token.

↪ **Anything else**

This is an invalid-first-character-of-tag-name[p1213] parse error[p1212]. Emit a U+003C LESS-THAN SIGN character token. Reconsume[p1229] in the data state[p1229].

13.2.5.7 End tag open state §[p1231]

Consume the next input character[p1224]:

↪ **ASCII alpha**

Create a new end tag token, set its tag name to the empty string. Reconsume[p1229] in the tag name state[p1232].

↪ **U+003E GREATER-THAN SIGN (>)**

This is a missing-end-tag-name[p1214] parse error[p1212]. Switch to the data state[p1229].

↪ **EOF**

This is an eof-before-tag-name[p1212] parse error[p1212]. Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token and an end-of-file token.

↪ **Anything else**

This is an invalid-first-character-of-tag-name[p1213] parse error[p1212]. Create a comment token whose data is the empty string. Reconsume[p1229] in the bogus comment state[p1243].

13.2.5.8 Tag name state §[p1232]

Consume the next input character[p1224]:

- ↪ **U+0009 CHARACTER TABULATION (tab)**
- ↪ **U+000A LINE FEED (LF)**
- ↪ **U+000C FORM FEED (FF)**
- ↪ **U+0020 SPACE**

  Switch to the before attribute name state[p1239].

- ↪ **U+002F SOLIDUS (/)**

  Switch to the self-closing start tag state[p1243].

- ↪ **U+003E GREATER-THAN SIGN (>)**

  Switch to the data state[p1229]. Emit the current tag token.

- ↪ **ASCII upper alpha**

  Append the lowercase version of the current input character[p1224] (add 0x0020 to the character's code point) to the current tag token's tag name.

- ↪ **U+0000 NULL**

  This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the current tag token's tag name.

- ↪ **EOF**

  This is an eof-in-tag[p1213] parse error[p1212]. Emit an end-of-file token.

- ↪ **Anything else**

  Append the current input character[p1224] to the current tag token's tag name.

13.2.5.9 RCDATA less-than sign state §[p1232]

Consume the next input character[p1224]:

- ↪ **U+002F SOLIDUS (/)**

  Set the *temporary buffer*[p1229] to the empty string. Switch to the RCDATA end tag open state[p1232].

- ↪ **Anything else**

  Emit a U+003C LESS-THAN SIGN character token. Reconsume[p1229] in the RCDATA state[p1230].

13.2.5.10 RCDATA end tag open state §[p1232]

Consume the next input character[p1224]:

- ↪ **ASCII alpha**

  Create a new end tag token, set its tag name to the empty string. Reconsume[p1229] in the RCDATA end tag name state[p1232].

- ↪ **Anything else**

  Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. Reconsume[p1229] in the RCDATA state[p1230].

13.2.5.11 RCDATA end tag name state §[p1232]

Consume the next input character[p1224]:

- ↪ **U+0009 CHARACTER TABULATION (tab)**
- ↪ **U+000A LINE FEED (LF)**
- ↪ **U+000C FORM FEED (FF)**
- ↪ **U+0020 SPACE**

  If the current end tag token is an appropriate end tag token[p1229], then switch to the before attribute name state[p1239]. Otherwise, treat it as per the "anything else" entry below.

- ↪ **U+002F SOLIDUS (/)**

  If the current end tag token is an appropriate end tag token[p1229], then switch to the self-closing start tag state[p1243]. Otherwise, treat it as per the "anything else" entry below.

- ↪ **U+003E GREATER-THAN SIGN (>)**

  If the current end tag token is an appropriate end tag token[p1229], then switch to the data state[p1229] and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

- ↪ **ASCII upper alpha**

  Append the lowercase version of the current input character[p1224] (add 0x0020 to the character's code point) to the current tag token's tag name. Append the current input character[p1224] to the *temporary buffer*[p1229].

- ↪ **ASCII lower alpha**

  Append the current input character[p1224] to the current tag token's tag name. Append the current input character[p1224] to the *temporary buffer*[p1229].

- ↪ **Anything else**

  Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the *temporary buffer*[p1229] (in the order they were added to the buffer). Reconsume[p1229] in the RCDATA state[p1230].

13.2.5.12 RAWTEXT less-than sign state §[p1233]

Consume the next input character[p1224]:

- ↪ **U+002F SOLIDUS (/)**

  Set the *temporary buffer*[p1229] to the empty string. Switch to the RAWTEXT end tag open state[p1233].

- ↪ **Anything else**

  Emit a U+003C LESS-THAN SIGN character token. Reconsume[p1229] in the RAWTEXT state[p1230].

13.2.5.13 RAWTEXT end tag open state §[p1233]

Consume the next input character[p1224]:

- ↪ **ASCII alpha**

  Create a new end tag token, set its tag name to the empty string. Reconsume[p1229] in the RAWTEXT end tag name state[p1233].

- ↪ **Anything else**

  Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. Reconsume[p1229] in the RAWTEXT state[p1230].

13.2.5.14 RAWTEXT end tag name state §[p1233]

Consume the next input character[p1224]:

- ↪ **U+0009 CHARACTER TABULATION (tab)**
- ↪ **U+000A LINE FEED (LF)**
- ↪ **U+000C FORM FEED (FF)**
- ↪ **U+0020 SPACE**

  If the current end tag token is an appropriate end tag token[p1229], then switch to the before attribute name state[p1239]. Otherwise, treat it as per the "anything else" entry below.

↪ **U+002F SOLIDUS (/)**

If the current end tag token is an appropriate end tag token[p1229], then switch to the self-closing start tag state[p1243]. Otherwise, treat it as per the "anything else" entry below.

↪ **U+003E GREATER-THAN SIGN (>)**

If the current end tag token is an appropriate end tag token[p1229], then switch to the data state[p1229] and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

↪ **ASCII upper alpha**

Append the lowercase version of the current input character[p1224] (add 0x0020 to the character's code point) to the current tag token's tag name. Append the current input character[p1224] to the *temporary buffer*[p1229].

↪ **ASCII lower alpha**

Append the current input character[p1224] to the current tag token's tag name. Append the current input character[p1224] to the *temporary buffer*[p1229].

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the *temporary buffer*[p1229] (in the order they were added to the buffer). Reconsume[p1229] in the RAWTEXT state[p1230].

13.2.5.15 Script data less-than sign state §[p1234]

Consume the next input character[p1224]:

↪ **U+002F SOLIDUS (/)**

Set the *temporary buffer*[p1229] to the empty string. Switch to the script data end tag open state[p1234].

↪ **U+0021 EXCLAMATION MARK (!)**

Switch to the script data escape start state[p1235]. Emit a U+003C LESS-THAN SIGN character token and a U+0021 EXCLAMATION MARK character token.

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token. Reconsume[p1229] in the script data state[p1230].

13.2.5.16 Script data end tag open state §[p1234]

Consume the next input character[p1224]:

↪ **ASCII alpha**

Create a new end tag token, set its tag name to the empty string. Reconsume[p1229] in the script data end tag name state[p1234].

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. Reconsume[p1229] in the script data state[p1230].

13.2.5.17 Script data end tag name state §[p1234]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

If the current end tag token is an appropriate end tag token[p1229], then switch to the before attribute name state[p1239]. Otherwise, treat it as per the "anything else" entry below.

↪ **U+002F SOLIDUS (/)**

If the current end tag token is an appropriate end tag token[p1229], then switch to the self-closing start tag state[p1243]. Otherwise, treat it as per the "anything else" entry below.

↪ **U+003E GREATER-THAN SIGN (>)**

If the current end tag token is an appropriate end tag token[p1229], then switch to the data state[p1229] and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

↪ **ASCII upper alpha**

Append the lowercase version of the current input character[p1224] (add 0x0020 to the character's code point) to the current tag token's tag name. Append the current input character[p1224] to the *temporary buffer*[p1229].

↪ **ASCII lower alpha**

Append the current input character[p1224] to the current tag token's tag name. Append the current input character[p1224] to the *temporary buffer*[p1229].

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the *temporary buffer*[p1229] (in the order they were added to the buffer). Reconsume[p1229] in the script data state[p1230].

13.2.5.18 Script data escape start state §[p1235]

Consume the next input character[p1224]:

↪ **U+002D HYPHEN-MINUS (-)**

Switch to the script data escape start dash state[p1235]. Emit a U+002D HYPHEN-MINUS character token.

↪ **Anything else**

Reconsume[p1229] in the script data state[p1230].

13.2.5.19 Script data escape start dash state §[p1235]

Consume the next input character[p1224]:

↪ **U+002D HYPHEN-MINUS (-)**

Switch to the script data escaped dash dash state[p1236]. Emit a U+002D HYPHEN-MINUS character token.

↪ **Anything else**

Reconsume[p1229] in the script data state[p1230].

13.2.5.20 Script data escaped state §[p1235]

Consume the next input character[p1224]:

↪ **U+002D HYPHEN-MINUS (-)**

Switch to the script data escaped dash state[p1235]. Emit a U+002D HYPHEN-MINUS character token.

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the script data escaped less-than sign state[p1236].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

This is an eof-in-script-html-comment-like-text[p1213] parse error[p1212]. Emit an end-of-file token.

↪ **Anything else**

Emit the current input character[p1224] as a character token.

13.2.5.21 Script data escaped dash state §[p1235]

Consume the next input character[p1224]:

↪ **U+002D HYPHEN-MINUS (-)**

Switch to the script data escaped dash dash state[p1236]. Emit a U+002D HYPHEN-MINUS character token.

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the script data escaped less-than sign state[p1236].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Switch to the script data escaped state[p1235]. Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

This is an eof-in-script-html-comment-like-text[p1213] parse error[p1212]. Emit an end-of-file token.

↪ **Anything else**

Switch to the script data escaped state[p1235]. Emit the current input character[p1224] as a character token.

13.2.5.22 Script data escaped dash dash state §[p1236]

Consume the next input character[p1224]:

↪ **U+002D HYPHEN-MINUS (-)**

Emit a U+002D HYPHEN-MINUS character token.

↪ **U+003C LESS-THAN SIGN (<)**

Switch to the script data escaped less-than sign state[p1236].

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the script data state[p1230]. Emit a U+003E GREATER-THAN SIGN character token.

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Switch to the script data escaped state[p1235]. Emit a U+FFFD REPLACEMENT CHARACTER character token.

↪ **EOF**

This is an eof-in-script-html-comment-like-text[p1213] parse error[p1212]. Emit an end-of-file token.

↪ **Anything else**

Switch to the script data escaped state[p1235]. Emit the current input character[p1224] as a character token.

13.2.5.23 Script data escaped less-than sign state §[p1236]

Consume the next input character[p1224]:

↪ **U+002F SOLIDUS (/)**

Set the *temporary buffer*[p1229] to the empty string. Switch to the script data escaped end tag open state[p1236].

↪ **ASCII alpha**

Set the *temporary buffer*[p1229] to the empty string. Emit a U+003C LESS-THAN SIGN character token. Reconsume[p1229] in the script data double escape start state[p1237].

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token. Reconsume[p1229] in the script data escaped state[p1235].

13.2.5.24 Script data escaped end tag open state §[p1236]

Consume the next input character[p1224]:

↪ **ASCII alpha**

Create a new end tag token, set its tag name to the empty string. Reconsume[p1229] in the script data escaped end tag name state[p1237].

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token and a U+002F SOLIDUS character token. Reconsume[p1229] in the script data escaped state[p1235].

13.2.5.25 Script data escaped end tag name state §[p1237]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

If the current end tag token is an appropriate end tag token[p1229], then switch to the before attribute name state[p1239]. Otherwise, treat it as per the "anything else" entry below.

↪ **U+002F SOLIDUS (/)**

If the current end tag token is an appropriate end tag token[p1229], then switch to the self-closing start tag state[p1243]. Otherwise, treat it as per the "anything else" entry below.

↪ **U+003E GREATER-THAN SIGN (>)**

If the current end tag token is an appropriate end tag token[p1229], then switch to the data state[p1229] and emit the current tag token. Otherwise, treat it as per the "anything else" entry below.

↪ **ASCII upper alpha**

Append the lowercase version of the current input character[p1224] (add 0x0020 to the character's code point) to the current tag token's tag name. Append the current input character[p1224] to the *temporary buffer*[p1229].

↪ **ASCII lower alpha**

Append the current input character[p1224] to the current tag token's tag name. Append the current input character[p1224] to the *temporary buffer*[p1229].

↪ **Anything else**

Emit a U+003C LESS-THAN SIGN character token, a U+002F SOLIDUS character token, and a character token for each of the characters in the *temporary buffer* [p1229] (in the order they were added to the buffer). Reconsume[p1229] in the script data escaped state[p1235].

13.2.5.26 Script data double escape start state §[p1237]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

↪ **U+002F SOLIDUS (/)**

↪ **U+003E GREATER-THAN SIGN (>)**

If the *temporary buffer*[p1229] is the string "`script`", then switch to the script data double escaped state[p1238]. Otherwise, switch to the script data escaped state[p1235]. Emit the current input character[p1224] as a character token.

↪ **ASCII upper alpha**

Append the lowercase version of the current input character[p1224] (add 0x0020 to the character's code point) to the *temporary buffer*[p1229]. Emit the current input character[p1224] as a character token.

↪ **ASCII lower alpha**

Append the current input character[p1224] to the *temporary buffer*[p1229]. Emit the current input character[p1224] as a character token.

↪ **Anything else**

Reconsume[p1229] in the script data escaped state[p1235].

13.2.5.27 Script data double escaped state §p1238

Consume the next input character p1224:

- ↪ **U+002D HYPHEN-MINUS (-)**
  Switch to the script data double escaped dash state p1238. Emit a U+002D HYPHEN-MINUS character token.
- ↪ **U+003C LESS-THAN SIGN (<)**
  Switch to the script data double escaped less-than sign state p1239. Emit a U+003C LESS-THAN SIGN character token.
- ↪ **U+0000 NULL**
  This is an unexpected-null-character p1216 parse error p1212. Emit a U+FFFD REPLACEMENT CHARACTER character token.
- ↪ **EOF**
  This is an eof-in-script-html-comment-like-text p1213 parse error p1212. Emit an end-of-file token.
- ↪ **Anything else**
  Emit the current input character p1224 as a character token.

13.2.5.28 Script data double escaped dash state §p1238

Consume the next input character p1224:

- ↪ **U+002D HYPHEN-MINUS (-)**
  Switch to the script data double escaped dash dash state p1238. Emit a U+002D HYPHEN-MINUS character token.
- ↪ **U+003C LESS-THAN SIGN (<)**
  Switch to the script data double escaped less-than sign state p1239. Emit a U+003C LESS-THAN SIGN character token.
- ↪ **U+0000 NULL**
  This is an unexpected-null-character p1216 parse error p1212. Switch to the script data double escaped state p1238. Emit a U+FFFD REPLACEMENT CHARACTER character token.
- ↪ **EOF**
  This is an eof-in-script-html-comment-like-text p1213 parse error p1212. Emit an end-of-file token.
- ↪ **Anything else**
  Switch to the script data double escaped state p1238. Emit the current input character p1224 as a character token.

13.2.5.29 Script data double escaped dash dash state §p1238

Consume the next input character p1224:

- ↪ **U+002D HYPHEN-MINUS (-)**
  Emit a U+002D HYPHEN-MINUS character token.
- ↪ **U+003C LESS-THAN SIGN (<)**
  Switch to the script data double escaped less-than sign state p1239. Emit a U+003C LESS-THAN SIGN character token.
- ↪ **U+003E GREATER-THAN SIGN (>)**
  Switch to the script data state p1230. Emit a U+003E GREATER-THAN SIGN character token.
- ↪ **U+0000 NULL**
  This is an unexpected-null-character p1216 parse error p1212. Switch to the script data double escaped state p1238. Emit a U+FFFD REPLACEMENT CHARACTER character token.
- ↪ **EOF**
  This is an eof-in-script-html-comment-like-text p1213 parse error p1212. Emit an end-of-file token.
- ↪ **Anything else**
  Switch to the script data double escaped state p1238. Emit the current input character p1224 as a character token.

13.2.5.30 Script data double escaped less-than sign state §p1239

Consume the next input character[p1224]:

- ↪ **U+002F SOLIDUS (/)**

  Set the *temporary buffer*[p1229] to the empty string. Switch to the script data double escape end state[p1239]. Emit a U+002F SOLIDUS character token.

- ↪ **Anything else**

  Reconsume[p1229] in the script data double escaped state[p1238].

13.2.5.31 Script data double escape end state §p1239

Consume the next input character[p1224]:

- ↪ **U+0009 CHARACTER TABULATION (tab)**
- ↪ **U+000A LINE FEED (LF)**
- ↪ **U+000C FORM FEED (FF)**
- ↪ **U+0020 SPACE**
- ↪ **U+002F SOLIDUS (/)**
- ↪ **U+003E GREATER-THAN SIGN (>)**

  If the *temporary buffer*[p1229] is the string "`script`", then switch to the script data escaped state[p1235]. Otherwise, switch to the script data double escaped state[p1238]. Emit the current input character[p1224] as a character token.

- ↪ **ASCII upper alpha**

  Append the lowercase version of the current input character[p1224] (add 0x0020 to the character's code point) to the *temporary buffer*[p1229]. Emit the current input character[p1224] as a character token.

- ↪ **ASCII lower alpha**

  Append the current input character[p1224] to the *temporary buffer*[p1229]. Emit the current input character[p1224] as a character token.

- ↪ **Anything else**

  Reconsume[p1229] in the script data double escaped state[p1238].

13.2.5.32 Before attribute name state §p1239

Consume the next input character[p1224]:

- ↪ **U+0009 CHARACTER TABULATION (tab)**
- ↪ **U+000A LINE FEED (LF)**
- ↪ **U+000C FORM FEED (FF)**
- ↪ **U+0020 SPACE**

  Ignore the character.

- ↪ **U+002F SOLIDUS (/)**
- ↪ **U+003E GREATER-THAN SIGN (>)**
- ↪ **EOF**

  Reconsume[p1229] in the after attribute name state[p1240].

- ↪ **U+003D EQUALS SIGN (=)**

  This is an unexpected-equals-sign-before-attribute-name[p1216] parse error[p1212]. Start a new attribute in the current tag token. Set that attribute's name to the current input character[p1224], and its value to the empty string. Switch to the attribute name state[p1240].

- ↪ **Anything else**

  Start a new attribute in the current tag token. Set that attribute name and value to the empty string. Reconsume[p1229] in the attribute name state[p1240].

13.2.5.33 Attribute name state §[p1240]

Consume the next input character[p1224]:

- ↪ **U+0009 CHARACTER TABULATION (tab)**
- ↪ **U+000A LINE FEED (LF)**
- ↪ **U+000C FORM FEED (FF)**
- ↪ **U+0020 SPACE**
- ↪ **U+002F SOLIDUS (/)**
- ↪ **U+003E GREATER-THAN SIGN (>)**
- ↪ **EOF**

  Reconsume[p1229] in the after attribute name state[p1240].

- ↪ **U+003D EQUALS SIGN (=)**

  Switch to the before attribute value state[p1241].

- ↪ **ASCII upper alpha**

  Append the lowercase version of the current input character[p1224] (add 0x0020 to the character's code point) to the current attribute's name.

- ↪ **U+0000 NULL**

  This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's name.

- ↪ **U+0022 QUOTATION MARK (")**
- ↪ **U+0027 APOSTROPHE (')**
- ↪ **U+003C LESS-THAN SIGN (<)**

  This is an unexpected-character-in-attribute-name[p1215] parse error[p1212]. Treat it as per the "anything else" entry below.

- ↪ **Anything else**

  Append the current input character[p1224] to the current attribute's name.

When the user agent leaves the attribute name state (and before emitting the tag token, if appropriate), the complete attribute's name must be compared to the other attributes on the same token; if there is already an attribute on the token with the exact same name, then this is a duplicate-attribute[p1212] parse error[p1212] and the new attribute must be removed from the token.

Note

If an attribute is so removed from a token, it, and the value that gets associated with it, if any, are never subsequently used by the parser, and are therefore effectively discarded. Removing the attribute in this way does not change its status as the "current attribute" for the purposes of the tokenizer, however.

13.2.5.34 After attribute name state §[p1240]

Consume the next input character[p1224]:

- ↪ **U+0009 CHARACTER TABULATION (tab)**
- ↪ **U+000A LINE FEED (LF)**
- ↪ **U+000C FORM FEED (FF)**
- ↪ **U+0020 SPACE**

  Ignore the character.

- ↪ **U+002F SOLIDUS (/)**

  Switch to the self-closing start tag state[p1243].

- ↪ **U+003D EQUALS SIGN (=)**

  Switch to the before attribute value state[p1241].

- ↪ **U+003E GREATER-THAN SIGN (>)**

  Switch to the data state[p1229]. Emit the current tag token.

↪ **EOF**

This is an eof-in-tag[p1213] parse error[p1212]. Emit an end-of-file token.

↪ **Anything else**

Start a new attribute in the current tag token. Set that attribute name and value to the empty string. Reconsume[p1229] in the attribute name state[p1240].

13.2.5.35 Before attribute value state §[p1241]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

Ignore the character.

↪ **U+0022 QUOTATION MARK (")**

Switch to the attribute value (double-quoted) state[p1241].

↪ **U+0027 APOSTROPHE (')**

Switch to the attribute value (single-quoted) state[p1241].

↪ **U+003E GREATER-THAN SIGN (>)**

This is a missing-attribute-value[p1213] parse error[p1212]. Switch to the data state[p1229]. Emit the current tag token.

↪ **Anything else**

Reconsume[p1229] in the attribute value (unquoted) state[p1242].

13.2.5.36 Attribute value (double-quoted) state §[p1241]

Consume the next input character[p1224]:

↪ **U+0022 QUOTATION MARK (")**

Switch to the after attribute value (quoted) state[p1242].

↪ **U+0026 AMPERSAND (&)**

Set the *return state*[p1229] to the attribute value (double-quoted) state[p1241]. Switch to the character reference state[p1254].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's value.

↪ **EOF**

This is an eof-in-tag[p1213] parse error[p1212]. Emit an end-of-file token.

↪ **Anything else**

Append the current input character[p1224] to the current attribute's value.

13.2.5.37 Attribute value (single-quoted) state §[p1241]

Consume the next input character[p1224]:

↪ **U+0027 APOSTROPHE (')**

Switch to the after attribute value (quoted) state[p1242].

↪ **U+0026 AMPERSAND (&)**

Set the *return state*[p1229] to the attribute value (single-quoted) state[p1241]. Switch to the character reference state[p1254].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's value.

↪ **EOF**

This is an eof-in-tag[p1213] parse error[p1212]. Emit an end-of-file token.

↪ **Anything else**

Append the current input character[p1224] to the current attribute's value.

13.2.5.38 Attribute value (unquoted) state §[p1242]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**
↪ **U+000A LINE FEED (LF)**
↪ **U+000C FORM FEED (FF)**
↪ **U+0020 SPACE**

Switch to the before attribute name state[p1239].

↪ **U+0026 AMPERSAND (&)**

Set the *return state*[p1229] to the attribute value (unquoted) state[p1242]. Switch to the character reference state[p1254].

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the data state[p1229]. Emit the current tag token.

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the current attribute's value.

↪ **U+0022 QUOTATION MARK (")**
↪ **U+0027 APOSTROPHE (')**
↪ **U+003C LESS-THAN SIGN (<)**
↪ **U+003D EQUALS SIGN (=)**
↪ **U+0060 GRAVE ACCENT (`)**

This is an unexpected-character-in-unquoted-attribute-value[p1215] parse error[p1212]. Treat it as per the "anything else" entry below.

↪ **EOF**

This is an eof-in-tag[p1213] parse error[p1212]. Emit an end-of-file token.

↪ **Anything else**

Append the current input character[p1224] to the current attribute's value.

13.2.5.39 After attribute value (quoted) state §[p1242]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**
↪ **U+000A LINE FEED (LF)**
↪ **U+000C FORM FEED (FF)**
↪ **U+0020 SPACE**

Switch to the before attribute name state[p1239].

↪ **U+002F SOLIDUS (/)**

Switch to the self-closing start tag state[p1243].

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the data state[p1229]. Emit the current tag token.

↪ **EOF**

This is an eof-in-tag[p1213] parse error[p1212]. Emit an end-of-file token.

↪ **Anything else**

This is a missing-whitespace-between-attributes[p1214] parse error[p1212]. Reconsume[p1229] in the before attribute name state[p1239].

13.2.5.40 Self-closing start tag state §[p1243]

Consume the next input character[p1224]:

↪ **U+003E GREATER-THAN SIGN (>)**

Set the *self-closing flag*[p1229] of the current tag token. Switch to the data state[p1229]. Emit the current tag token.

↪ **EOF**

This is an eof-in-tag[p1213] parse error[p1212]. Emit an end-of-file token.

↪ **Anything else**

This is an unexpected-solidus-in-tag[p1216] parse error[p1212]. Reconsume[p1229] in the before attribute name state[p1239].

13.2.5.41 Bogus comment state §[p1243]

Consume the next input character[p1224]:

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the data state[p1229]. Emit the current comment token.

↪ **EOF**

Emit the comment. Emit an end-of-file token.

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the comment token's data.

↪ **Anything else**

Append the current input character[p1224] to the comment token's data.

13.2.5.42 Markup declaration open state §[p1243]

If the next few characters are:

↪ **Two U+002D HYPHEN-MINUS characters (-)**

Consume those two characters, create a comment token whose data is the empty string, and switch to the comment start state[p1244].

↪ **ASCII case-insensitive match for the word "DOCTYPE"**

Consume those characters and switch to the DOCTYPE state[p1246].

↪ **The string "[CDATA[" (the five uppercase letters "CDATA" with a U+005B LEFT SQUARE BRACKET character before and after)**

Consume those characters. If there is an adjusted current node[p1226] and it is not an element in the HTML namespace, then switch to the CDATA section state[p1253]. Otherwise, this is a cdata-in-html-content[p1212] parse error[p1212]. Create a comment token whose data is the "[CDATA[" string. Switch to the bogus comment state[p1243].

↪ **Anything else**

This is an incorrectly-opened-comment[p1213] parse error[p1212]. Create a comment token whose data is the empty string. Switch to the bogus comment state[p1243] (don't consume anything in the current state).

13.2.5.43 Comment start state §p1244

Consume the next input character[p1224]:

- **U+002D HYPHEN-MINUS (-)**
  Switch to the comment start dash state[p1244].
- **U+003E GREATER-THAN SIGN (>)**
  This is an abrupt-closing-of-empty-comment[p1212] parse error[p1212]. Switch to the data state[p1229]. Emit the current comment token.
- **Anything else**
  Reconsume[p1229] in the comment state[p1244].

13.2.5.44 Comment start dash state §p1244

Consume the next input character[p1224]:

- **U+002D HYPHEN-MINUS (-)**
  Switch to the comment end state[p1245].
- **U+003E GREATER-THAN SIGN (>)**
  This is an abrupt-closing-of-empty-comment[p1212] parse error[p1212]. Switch to the data state[p1229]. Emit the current comment token.
- **EOF**
  This is an eof-in-comment[p1213] parse error[p1212]. Emit the current comment token. Emit an end-of-file token.
- **Anything else**
  Append a U+002D HYPHEN-MINUS character (-) to the comment token's data. Reconsume[p1229] in the comment state[p1244].

13.2.5.45 Comment state §p1244

Consume the next input character[p1224]:

- **U+003C LESS-THAN SIGN (<)**
  Append the current input character[p1224] to the comment token's data. Switch to the comment less-than sign state[p1244].
- **U+002D HYPHEN-MINUS (-)**
  Switch to the comment end dash state[p1245].
- **U+0000 NULL**
  This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the comment token's data.
- **EOF**
  This is an eof-in-comment[p1213] parse error[p1212]. Emit the current comment token. Emit an end-of-file token.
- **Anything else**
  Append the current input character[p1224] to the comment token's data.

13.2.5.46 Comment less-than sign state §p1244

Consume the next input character[p1224]:

- **U+0021 EXCLAMATION MARK (!)**
  Append the current input character[p1224] to the comment token's data. Switch to the comment less-than sign bang state[p1245].
- **U+003C LESS-THAN SIGN (<)**
  Append the current input character[p1224] to the comment token's data.
- **Anything else**
  Reconsume[p1229] in the comment state[p1244].

13.2.5.47 Comment less-than sign bang state §p1245

Consume the next input character[p1224]:

- ↪ **U+002D HYPHEN-MINUS (-)**
  Switch to the comment less-than sign bang dash state[p1245].
- ↪ **Anything else**
  Reconsume[p1229] in the comment state[p1244].

13.2.5.48 Comment less-than sign bang dash state §p1245

Consume the next input character[p1224]:

- ↪ **U+002D HYPHEN-MINUS (-)**
  Switch to the comment less-than sign bang dash dash state[p1245].
- ↪ **Anything else**
  Reconsume[p1229] in the comment end dash state[p1245].

13.2.5.49 Comment less-than sign bang dash dash state §p1245

Consume the next input character[p1224]:

- ↪ **U+003E GREATER-THAN SIGN (>)**
- ↪ **EOF**
  Reconsume[p1229] in the comment end state[p1245].
- ↪ **Anything else**
  This is a nested-comment[p1214] parse error[p1212]. Reconsume[p1229] in the comment end state[p1245].

13.2.5.50 Comment end dash state §p1245

Consume the next input character[p1224]:

- ↪ **U+002D HYPHEN-MINUS (-)**
  Switch to the comment end state[p1245].
- ↪ **EOF**
  This is an eof-in-comment[p1213] parse error[p1212]. Emit the current comment token. Emit an end-of-file token.
- ↪ **Anything else**
  Append a U+002D HYPHEN-MINUS character (-) to the comment token's data. Reconsume[p1229] in the comment state[p1244].

13.2.5.51 Comment end state §p1245

Consume the next input character[p1224]:

- ↪ **U+003E GREATER-THAN SIGN (>)**
  Switch to the data state[p1229]. Emit the current comment token.
- ↪ **U+0021 EXCLAMATION MARK (!)**
  Switch to the comment end bang state[p1246].
- ↪ **U+002D HYPHEN-MINUS (-)**
  Append a U+002D HYPHEN-MINUS character (-) to the comment token's data.

↪ **EOF**

This is an eof-in-comment[p1213] parse error[p1212]. Emit the current comment token. Emit an end-of-file token.

↪ **Anything else**

Append two U+002D HYPHEN-MINUS characters (-) to the comment token's data. Reconsume[p1229] in the comment state[p1244].

13.2.5.52 Comment end bang state §[p1246]

Consume the next input character[p1224]:

↪ **U+002D HYPHEN-MINUS (-)**

Append two U+002D HYPHEN-MINUS characters (-) and a U+0021 EXCLAMATION MARK character (!) to the comment token's data. Switch to the comment end dash state[p1245].

↪ **U+003E GREATER-THAN SIGN (>)**

This is an incorrectly-closed-comment[p1213] parse error[p1212]. Switch to the data state[p1229]. Emit the current comment token.

↪ **EOF**

This is an eof-in-comment[p1213] parse error[p1212]. Emit the current comment token. Emit an end-of-file token.

↪ **Anything else**

Append two U+002D HYPHEN-MINUS characters (-) and a U+0021 EXCLAMATION MARK character (!) to the comment token's data. Reconsume[p1229] in the comment state[p1244].

13.2.5.53 DOCTYPE state §[p1246]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**
↪ **U+000A LINE FEED (LF)**
↪ **U+000C FORM FEED (FF)**
↪ **U+0020 SPACE**

Switch to the before DOCTYPE name state[p1246].

↪ **U+003E GREATER-THAN SIGN (>)**

Reconsume[p1229] in the before DOCTYPE name state[p1246].

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Create a new DOCTYPE token. Set its *force-quirks flag*[p1229] to *on*. Emit the current token. Emit an end-of-file token.

↪ **Anything else**

This is a missing-whitespace-before-doctype-name[p1214] parse error[p1212]. Reconsume[p1229] in the before DOCTYPE name state[p1246].

13.2.5.54 Before DOCTYPE name state §[p1246]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**
↪ **U+000A LINE FEED (LF)**
↪ **U+000C FORM FEED (FF)**
↪ **U+0020 SPACE**

Ignore the character.

↪ **ASCII upper alpha**

Create a new DOCTYPE token. Set the token's name to the lowercase version of the current input character[p1224] (add 0x0020 to the character's code point). Switch to the DOCTYPE name state[p1247].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Create a new DOCTYPE token. Set the token's name to a U+FFFD REPLACEMENT CHARACTER character. Switch to the DOCTYPE name state[p1247].

↪ **U+003E GREATER-THAN SIGN (>)**

This is a missing-doctype-name[p1213] parse error[p1212]. Create a new DOCTYPE token. Set its *force-quirks flag*[p1229] to *on*. Switch to the data state[p1229]. Emit the current token.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Create a new DOCTYPE token. Set its *force-quirks flag*[p1229] to *on*. Emit the current token. Emit an end-of-file token.

↪ **Anything else**

Create a new DOCTYPE token. Set the token's name to the current input character[p1224]. Switch to the DOCTYPE name state[p1247].

13.2.5.55 DOCTYPE name state §[p1247]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**
↪ **U+000A LINE FEED (LF)**
↪ **U+000C FORM FEED (FF)**
↪ **U+0020 SPACE**

Switch to the after DOCTYPE name state[p1247].

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **ASCII upper alpha**

Append the lowercase version of the current input character[p1224] (add 0x0020 to the character's code point) to the current DOCTYPE token's name.

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token's name.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

Append the current input character[p1224] to the current DOCTYPE token's name.

13.2.5.56 After DOCTYPE name state §[p1247]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**
↪ **U+000A LINE FEED (LF)**
↪ **U+000C FORM FEED (FF)**
↪ **U+0020 SPACE**

Ignore the character.

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

If the six characters starting from the current input character[p1224] are an ASCII case-insensitive match for the word "PUBLIC", then consume those characters and switch to the after DOCTYPE public keyword state[p1248].

Otherwise, if the six characters starting from the current input character[p1224] are an ASCII case-insensitive match for the word "SYSTEM", then consume those characters and switch to the after DOCTYPE system keyword state[p1250].

Otherwise, this is an invalid-character-sequence-after-doctype-name[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Reconsume[p1229] in the bogus DOCTYPE state[p1253].

13.2.5.57 After DOCTYPE public keyword state §[p1248]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

Switch to the before DOCTYPE public identifier state[p1248].

↪ **U+0022 QUOTATION MARK (")**

This is a missing-whitespace-after-doctype-public-keyword[p1214] parse error[p1212]. Set the current DOCTYPE token's public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (double-quoted) state[p1249].

↪ **U+0027 APOSTROPHE (')**

This is a missing-whitespace-after-doctype-public-keyword[p1214] parse error[p1212]. Set the current DOCTYPE token's public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (single-quoted) state[p1249].

↪ **U+003E GREATER-THAN SIGN (>)**

This is a missing-doctype-public-identifier[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

This is a missing-quote-before-doctype-public-identifier[p1214] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Reconsume[p1229] in the bogus DOCTYPE state[p1253].

13.2.5.58 Before DOCTYPE public identifier state §[p1248]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

Ignore the character.

↪ **U+0022 QUOTATION MARK (")**

Set the current DOCTYPE token's public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (double-quoted) state[p1249].

↪ **U+0027 APOSTROPHE (')**

Set the current DOCTYPE token's public identifier to the empty string (not missing), then switch to the DOCTYPE public identifier (single-quoted) state[p1249].

↪ **U+003E GREATER-THAN SIGN (>)**

This is a missing-doctype-public-identifier[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*.

Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

This is a missing-quote-before-doctype-public-identifier[p1214] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Reconsume[p1229] in the bogus DOCTYPE state[p1253].

13.2.5.59 DOCTYPE public identifier (double-quoted) state §[p1249]

Consume the next input character[p1224]:

↪ **U+0022 QUOTATION MARK (")**

Switch to the after DOCTYPE public identifier state[p1249].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token's public identifier.

↪ **U+003E GREATER-THAN SIGN (>)**

This is an abrupt-doctype-public-identifier[p1212] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

Append the current input character[p1224] to the current DOCTYPE token's public identifier.

13.2.5.60 DOCTYPE public identifier (single-quoted) state §[p1249]

Consume the next input character[p1224]:

↪ **U+0027 APOSTROPHE (')**

Switch to the after DOCTYPE public identifier state[p1249].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token's public identifier.

↪ **U+003E GREATER-THAN SIGN (>)**

This is an abrupt-doctype-public-identifier[p1212] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

Append the current input character[p1224] to the current DOCTYPE token's public identifier.

13.2.5.61 After DOCTYPE public identifier state §[p1249]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

Switch to the between DOCTYPE public and system identifiers state[p1250].

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **U+0022 QUOTATION MARK (")**

This is a missing-whitespace-between-doctype-public-and-system-identifiers[p1214] parse error[p1212]. Set the current DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (double-quoted) state[p1251].

↪ **U+0027 APOSTROPHE (')**

This is a missing-whitespace-between-doctype-public-and-system-identifiers[p1214] parse error[p1212]. Set the current DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (single-quoted) state[p1252].

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

This is a missing-quote-before-doctype-system-identifier[p1214] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Reconsume[p1229] in the bogus DOCTYPE state[p1253].

13.2.5.62 Between DOCTYPE public and system identifiers state §[p1250]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

Ignore the character.

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **U+0022 QUOTATION MARK (")**

Set the current DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (double-quoted) state[p1251].

↪ **U+0027 APOSTROPHE (')**

Set the current DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (single-quoted) state[p1252].

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

This is a missing-quote-before-doctype-system-identifier[p1214] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Reconsume[p1229] in the bogus DOCTYPE state[p1253].

13.2.5.63 After DOCTYPE system keyword state §[p1250]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**
↪ **U+000A LINE FEED (LF)**
↪ **U+000C FORM FEED (FF)**
↪ **U+0020 SPACE**

Switch to the before DOCTYPE system identifier state[p1251].

↪ **U+0022 QUOTATION MARK (")**

This is a missing-whitespace-after-doctype-system-keyword[p1214] parse error[p1212]. Set the current DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (double-quoted) state[p1251].

↪ **U+0027 APOSTROPHE (')**

This is a missing-whitespace-after-doctype-system-keyword[p1214] parse error[p1212]. Set the current DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (single-quoted) state[p1252].

↪ **U+003E GREATER-THAN SIGN (>)**

This is a missing-doctype-system-identifier[p1214] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

This is a missing-quote-before-doctype-system-identifier[p1214] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Reconsume[p1229] in the bogus DOCTYPE state[p1253].

13.2.5.64 Before DOCTYPE system identifier state §[p1251]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**
↪ **U+000A LINE FEED (LF)**
↪ **U+000C FORM FEED (FF)**
↪ **U+0020 SPACE**

Ignore the character.

↪ **U+0022 QUOTATION MARK (")**

Set the current DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (double-quoted) state[p1251].

↪ **U+0027 APOSTROPHE (')**

Set the current DOCTYPE token's system identifier to the empty string (not missing), then switch to the DOCTYPE system identifier (single-quoted) state[p1252].

↪ **U+003E GREATER-THAN SIGN (>)**

This is a missing-doctype-system-identifier[p1214] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

This is a missing-quote-before-doctype-system-identifier[p1214] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Reconsume[p1229] in the bogus DOCTYPE state[p1253].

13.2.5.65 DOCTYPE system identifier (double-quoted) state §[p1251]

Consume the next input character[p1224]:

↪ **U+0022 QUOTATION MARK (")**

Switch to the after DOCTYPE system identifier state[p1252].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token's system identifier.

↪ **U+003E GREATER-THAN SIGN (>)**

This is an abrupt-doctype-system-identifier[p1212] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

Append the current input character[p1224] to the current DOCTYPE token's system identifier.

13.2.5.66 DOCTYPE system identifier (single-quoted) state §[p1252]

Consume the next input character[p1224]:

↪ **U+0027 APOSTROPHE (')**

Switch to the after DOCTYPE system identifier state[p1252].

↪ **U+0000 NULL**

This is an unexpected-null-character[p1216] parse error[p1212]. Append a U+FFFD REPLACEMENT CHARACTER character to the current DOCTYPE token's system identifier.

↪ **U+003E GREATER-THAN SIGN (>)**

This is an abrupt-doctype-system-identifier[p1212] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

Append the current input character[p1224] to the current DOCTYPE token's system identifier.

13.2.5.67 After DOCTYPE system identifier state §[p1252]

Consume the next input character[p1224]:

↪ **U+0009 CHARACTER TABULATION (tab)**

↪ **U+000A LINE FEED (LF)**

↪ **U+000C FORM FEED (FF)**

↪ **U+0020 SPACE**

Ignore the character.

↪ **U+003E GREATER-THAN SIGN (>)**

Switch to the data state[p1229]. Emit the current DOCTYPE token.

↪ **EOF**

This is an eof-in-doctype[p1213] parse error[p1212]. Set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*. Emit the current DOCTYPE token. Emit an end-of-file token.

↪ **Anything else**

This is an unexpected-character-after-doctype-system-identifier[p1215] parse error[p1212]. Reconsume[p1229] in the bogus DOCTYPE state[p1253]. (This does *not* set the current DOCTYPE token's *force-quirks flag*[p1229] to *on*.)

13.2.5.68 Bogus DOCTYPE state §p1253

Consume the next input characterp1224:

- ↪ **U+003E GREATER-THAN SIGN (>)**
  Switch to the data statep1229. Emit the DOCTYPE token.
- ↪ **U+0000 NULL**
  This is an unexpected-null-characterp1216 parse errorp1212. Ignore the character.
- ↪ **EOF**
  Emit the DOCTYPE token. Emit an end-of-file token.
- ↪ **Anything else**
  Ignore the character.

13.2.5.69 CDATA section state §p1253

Consume the next input characterp1224:

- ↪ **U+005D RIGHT SQUARE BRACKET (])**
  Switch to the CDATA section bracket statep1253.
- ↪ **EOF**
  This is an eof-in-cdatap1213 parse errorp1212. Emit an end-of-file token.
- ↪ **Anything else**
  Emit the current input characterp1224 as a character token.

Note

U+0000 NULL characters are handled in the tree construction stage, as part of the in foreign contentp1294 insertion mode, which is the only place where CDATA sections can appear.

13.2.5.70 CDATA section bracket state §p1253

Consume the next input characterp1224:

- ↪ **U+005D RIGHT SQUARE BRACKET (])**
  Switch to the CDATA section end statep1253.
- ↪ **Anything else**
  Emit a U+005D RIGHT SQUARE BRACKET character token. Reconsumep1229 in the CDATA section statep1253.

13.2.5.71 CDATA section end state §p1253

Consume the next input characterp1224:

- ↪ **U+005D RIGHT SQUARE BRACKET (])**
  Emit a U+005D RIGHT SQUARE BRACKET character token.
- ↪ **U+003E GREATER-THAN SIGN character**
  Switch to the data statep1229.
- ↪ **Anything else**
  Emit two U+005D RIGHT SQUARE BRACKET character tokens. Reconsumep1229 in the CDATA section statep1253.

13.2.5.72 Character reference state §p1254

Set the *temporary buffer*p1229 to the empty string. Append a U+0026 AMPERSAND (&) character to the *temporary buffer*p1229. Consume the next input characterp1224:

↪ **ASCII alphanumeric**

Reconsumep1229 in the named character reference statep1254.

↪ **U+0023 NUMBER SIGN (#)**

Append the current input characterp1224 to the *temporary buffer*p1229. Switch to the numeric character reference statep1255.

↪ **Anything else**

Flush code points consumed as a character referencep1229. Reconsumep1229 in the *return state*p1229.

13.2.5.73 Named character reference state §p1254

Consume the maximum number of characters possible, where the consumed characters are one of the identifiers in the first column of the named character referencesp1312 table. Append each character to the *temporary buffer*p1229 when it's consumed.

↪ **If there is a match**

If the character reference was consumed as part of an attributep1229, and the last character matched is not a U+003B SEMICOLON character (;), and the next input characterp1224 is either a U+003D EQUALS SIGN character (=) or an ASCII alphanumeric, then, for historical reasons, flush code points consumed as a character referencep1229 and switch to the *return state*p1229.

Otherwise:

1. If the last character matched is not a U+003B SEMICOLON character (;), then this is a missing-semicolon-after-character-referencep1214 parse errorp1212.
2. Set the *temporary buffer*p1229 to the empty string. Append one or two characters corresponding to the character reference name (as given by the second column of the named character referencesp1312 table) to the *temporary buffer*p1229.
3. Flush code points consumed as a character referencep1229. Switch to the *return state*p1229.

↪ **Otherwise**

Flush code points consumed as a character referencep1229. Switch to the ambiguous ampersand statep1254.

Example

If the markup contains (not in an attribute) the string `I'm &notit; I tell you`, the character reference is parsed as "not", as in, `I'm ¬it; I tell you` (and this is a parse error). But if the markup was `I'm ∉ I tell you`, the character reference would be parsed as "notin;", resulting in `I'm ∉ I tell you` (and no parse error).

However, if the markup contains the string `I'm &notit; I tell you` in an attribute, no character reference is parsed and string remains intact (and there is no parse error).

13.2.5.74 Ambiguous ampersand state §p1254

Consume the next input characterp1224:

↪ **ASCII alphanumeric**

If the character reference was consumed as part of an attributep1229, then append the current input characterp1224 to the current attribute's value. Otherwise, emit the current input characterp1224 as a character token.

↪ **U+003B SEMICOLON (;)**

This is an unknown-named-character-referencep1216 parse errorp1212. Reconsumep1229 in the *return state*p1229.

↪ **Anything else**

Reconsumep1229 in the *return state*p1229.

13.2.5.75 Numeric character reference state §p1255

Set the ***character reference code*** to zero (0).

Consume the next input character[p1224]:

- ↪ **U+0078 LATIN SMALL LETTER X**
- ↪ **U+0058 LATIN CAPITAL LETTER X**

  Append the current input character[p1224] to the *temporary buffer*[p1229]. Switch to the hexadecimal character reference start state[p1255].

- ↪ **Anything else**

  Reconsume[p1229] in the decimal character reference start state[p1255].

13.2.5.76 Hexadecimal character reference start state §p1255

Consume the next input character[p1224]:

- ↪ **ASCII hex digit**

  Reconsume[p1229] in the hexadecimal character reference state[p1255].

- ↪ **Anything else**

  This is an absence-of-digits-in-numeric-character-reference[p1212] parse error[p1212]. Flush code points consumed as a character reference[p1229]. Reconsume[p1229] in the *return state*[p1229].

13.2.5.77 Decimal character reference start state §p1255

Consume the next input character[p1224]:

- ↪ **ASCII digit**

  Reconsume[p1229] in the decimal character reference state[p1256].

- ↪ **Anything else**

  This is an absence-of-digits-in-numeric-character-reference[p1212] parse error[p1212]. Flush code points consumed as a character reference[p1229]. Reconsume[p1229] in the *return state*[p1229].

13.2.5.78 Hexadecimal character reference state §p1255

Consume the next input character[p1224]:

- ↪ **ASCII digit**

  Multiply the *character reference code*[p1255] by 16. Add a numeric version of the current input character[p1224] (subtract 0x0030 from the character's code point) to the *character reference code*[p1255].

- ↪ **ASCII upper hex digit**

  Multiply the *character reference code*[p1255] by 16. Add a numeric version of the current input character[p1224] as a hexadecimal digit (subtract 0x0037 from the character's code point) to the *character reference code*[p1255].

- ↪ **ASCII lower hex digit**

  Multiply the *character reference code*[p1255] by 16. Add a numeric version of the current input character[p1224] as a hexadecimal digit (subtract 0x0057 from the character's code point) to the *character reference code*[p1255].

- ↪ **U+003B SEMICOLON**

  Switch to the numeric character reference end state[p1256].

- ↪ **Anything else**

  This is a missing-semicolon-after-character-reference[p1214] parse error[p1212]. Reconsume[p1229] in the numeric character reference end state[p1256].

13.2.5.79 Decimal character reference state §p1256

Consume the next input character[p1224]:

↪ **ASCII digit**

Multiply the *character reference code*[p1255] by 10. Add a numeric version of the current input character[p1224] (subtract 0x0030 from the character's code point) to the *character reference code*[p1255].

↪ **U+003B SEMICOLON**

Switch to the numeric character reference end state[p1256].

↪ **Anything else**

This is a missing-semicolon-after-character-reference[p1214] parse error[p1212]. Reconsume[p1229] in the numeric character reference end state[p1256].

13.2.5.80 Numeric character reference end state §p1256

Check the *character reference code*[p1255]:

- If the number is 0x00, then this is a null-character-reference[p1215] parse error[p1212]. Set the *character reference code*[p1255] to 0xFFFD.
- If the number is greater than 0x10FFFF, then this is a character-reference-outside-unicode-range[p1212] parse error[p1212]. Set the *character reference code*[p1255] to 0xFFFD.
- If the number is a surrogate, then this is a surrogate-character-reference[p1215] parse error[p1212]. Set the *character reference code*[p1255] to 0xFFFD.
- If the number is a noncharacter, then this is a noncharacter-character-reference[p1214] parse error[p1212].
- If the number is 0x0D, or a control that's not ASCII whitespace, then this is a control-character-reference[p1212] parse error[p1212]. If the number is one of the numbers in the first column of the following table, then find the row with that number in the first column, and set the *character reference code*[p1255] to the number in the second column of that row.

Number	Code point	
0x80	0x20AC	EURO SIGN (€)
0x82	0x201A	SINGLE LOW-9 QUOTATION MARK (‚)
0x83	0x0192	LATIN SMALL LETTER F WITH HOOK (ƒ)
0x84	0x201E	DOUBLE LOW-9 QUOTATION MARK („)
0x85	0x2026	HORIZONTAL ELLIPSIS (…)
0x86	0x2020	DAGGER (†)
0x87	0x2021	DOUBLE DAGGER (‡)
0x88	0x02C6	MODIFIER LETTER CIRCUMFLEX ACCENT (ˆ)
0x89	0x2030	PER MILLE SIGN (‰)
0x8A	0x0160	LATIN CAPITAL LETTER S WITH CARON (Š)
0x8B	0x2039	SINGLE LEFT-POINTING ANGLE QUOTATION MARK (‹)
0x8C	0x0152	LATIN CAPITAL LIGATURE OE (Œ)
0x8E	0x017D	LATIN CAPITAL LETTER Z WITH CARON (Ž)
0x91	0x2018	LEFT SINGLE QUOTATION MARK (‘)
0x92	0x2019	RIGHT SINGLE QUOTATION MARK (’)
0x93	0x201C	LEFT DOUBLE QUOTATION MARK (“)
0x94	0x201D	RIGHT DOUBLE QUOTATION MARK (”)
0x95	0x2022	BULLET (•)
0x96	0x2013	EN DASH (–)
0x97	0x2014	EM DASH (—)
0x98	0x02DC	SMALL TILDE (˜)
0x99	0x2122	TRADE MARK SIGN (™)
0x9A	0x0161	LATIN SMALL LETTER S WITH CARON (š)
0x9B	0x203A	SINGLE RIGHT-POINTING ANGLE QUOTATION MARK (›)
0x9C	0x0153	LATIN SMALL LIGATURE OE (œ)

Number	Code point	
0x9E	0x017E	LATIN SMALL LETTER Z WITH CARON (ž)
0x9F	0x0178	LATIN CAPITAL LETTER Y WITH DIAERESIS (Ÿ)

Set the *temporary buffer*[p1229] to the empty string. Append a code point equal to the *character reference code*[p1255] to the *temporary buffer*[p1229]. Flush code points consumed as a character reference[p1229]. Switch to the *return state*[p1229].

13.2.6 Tree construction §[p1257]

The input to the tree construction stage is a sequence of tokens from the tokenization[p1229] stage. The tree construction stage is associated with a DOM `Document`[p127] object when a parser is created. The "output" of this stage consists of dynamically modifying or extending that document's DOM tree.

This specification does not define when an interactive user agent has to render the `Document`[p127] so that it is available to the user, or when it has to begin accepting user input.

As each token is emitted from the tokenizer, the user agent must follow the appropriate steps from the following list, known as the **tree construction dispatcher**:

- ↪ **If the stack of open elements[p1225] is empty**
- ↪ **If the adjusted current node[p1226] is an element in the HTML namespace**
- ↪ **If the adjusted current node[p1226] is a MathML text integration point[p1257] and the token is a start tag whose tag name is neither "mglyph" nor "malignmark"**
- ↪ **If the adjusted current node[p1226] is a MathML text integration point[p1257] and the token is a character token**
- ↪ **If the adjusted current node[p1226] is a MathML `annotation-xml` element and the token is a start tag whose tag name is "svg"**
- ↪ **If the adjusted current node[p1226] is an HTML integration point[p1257] and the token is a start tag**
- ↪ **If the adjusted current node[p1226] is an HTML integration point[p1257] and the token is a character token**
- ↪ **If the token is an end-of-file token**

  Process the token according to the rules given in the section corresponding to the current insertion mode[p1224] in HTML content.

- ↪ **Otherwise**

  Process the token according to the rules given in the section for parsing tokens in foreign content[p1294].

The **next token** is the token that is about to be processed by the tree construction dispatcher[p1257] (even if the token is subsequently just ignored).

A node is a **MathML text integration point** if it is one of the following elements:

- A MathML `mi` element
- A MathML `mo` element
- A MathML `mn` element
- A MathML `ms` element
- A MathML `mtext` element

A node is an **HTML integration point** if it is one of the following elements:

- A MathML `annotation-xml` element whose start tag token had an attribute with the name "encoding" whose value was an ASCII case-insensitive match for the string "`text/html`"
- A MathML `annotation-xml` element whose start tag token had an attribute with the name "encoding" whose value was an ASCII case-insensitive match for the string "`application/xhtml+xml`"
- An SVG `foreignObject` element
- An SVG `desc` element
- An SVG `title` element

Note

If the node in question is the context[p1310] element passed to the HTML fragment parsing algorithm[p1310], then the start tag token for that element is the "fake" token created during by that HTML fragment parsing algorithm[p1310].

Note

Not all of the tag names mentioned below are conformant tag names in this specification; many are included to handle legacy content. They still form part of the algorithm that implementations are required to implement to claim conformance.

Note

The algorithm described below places no limit on the depth of the DOM tree generated, or on the length of tag names, attribute names, attribute values, `Text` nodes, etc. While implementers are encouraged to avoid arbitrary limits, it is recognized that practical concerns will likely force user agents to impose nesting depth constraints.

13.2.6.1 Creating and inserting nodes §[p1258]

While the parser is processing a token, it can enable or disable **foster parenting**. This affects the following algorithm.

The **appropriate place for inserting a node**, optionally using a particular *override target*, is the position in an element returned by running the following steps:

1. If there was an *override target* specified, then let *target* be the *override target*.

   Otherwise, let *target* be the current node[p1225].

2. Determine the *adjusted insertion location* using the first matching steps from the following list:

   ↪ **If foster parenting[p1258] is enabled and *target* is a `table`[p469], `tbody`[p480], `tfoot`[p482], `thead`[p481], or `tr`[p483] element**

   Note

   Foster parenting happens when content is misnested in tables.

   Run these substeps:

   1. Let *last template* be the last `template`[p656] element in the stack of open elements[p1225], if any.
   2. Let *last table* be the last `table`[p469] element in the stack of open elements[p1225], if any.
   3. If there is a *last template* and either there is no *last table*, or there is one, but *last template* is lower (more recently added) than *last table* in the stack of open elements[p1225], then: let *adjusted insertion location* be inside *last template*'s template contents[p657], after its last child (if any), and abort these steps.
   4. If there is no *last table*, then let *adjusted insertion location* be inside the first element in the stack of open elements[p1225] (the `html`[p167] element), after its last child (if any), and abort these steps. (fragment case[p1311])
   5. If *last table* has a parent node, then let *adjusted insertion location* be inside *last table*'s parent node, immediately before *last table*, and abort these steps.
   6. Let *previous element* be the element immediately above *last table* in the stack of open elements[p1225].
   7. Let *adjusted insertion location* be inside *previous element*, after its last child (if any).

   Note

   These steps are involved in part because it's possible for elements, the `table`[p469] element in this case in particular, to have been moved by a script around in the DOM, or indeed removed from the DOM entirely, after the element was inserted by the parser.

   ↪ **Otherwise**

   Let *adjusted insertion location* be inside *target*, after its last child (if any).

3. If the *adjusted insertion location* is inside a `template`[p656] element, let it instead be inside the `template`[p656] element's template contents[p657], after its last child (if any).

4. Return the *adjusted insertion location*.

When the steps below require the UA to **create an element for a token** in a particular *given namespace* and with a particular

intended parent, the UA must run the following steps:

1. If the active speculative HTML parser[p1298] is not null, then return the result of creating a speculative mock element[p1299] given *given namespace*, the tag name of the given token, and the attributes of the given token.

2. Otherwise, optionally create a speculative mock element[p1299] given *given namespace*, the tag name of the given token, and the attributes of the given token.

   Note

   The result is not used. This step allows for a speculative fetch[p1298] to be initiated from non-speculative parsing. The fetch is still speculative at this point, because, for example, by the time the element is inserted, intended parent *might have been removed from the document.*

3. Let *document* be *intended parent*'s node document.

4. Let *local name* be the tag name of the token.

5. Let *is* be the value of the "`is`[p742]" attribute in the given token, if such an attribute exists, or null otherwise.

6. Let *definition* be the result of looking up a custom element definition[p744] given *document*, *given namespace*, *local name*, and *is*.

7. If *definition* is non-null and the parser was not created as part of the HTML fragment parsing algorithm[p1310], then let *will execute script* be true. Otherwise, let it be false.

8. If *will execute script* is true, then:

   1. Increment *document*'s throw-on-dynamic-markup-insertion counter[p1096].

   2. If the JavaScript execution context stack is empty, then perform a microtask checkpoint[p1077].

   3. Push a new element queue[p751] onto *document*'s relevant agent[p1029]'s custom element reactions stack[p751].

9. Let *element* be the result of creating an element given *document*, *localName*, *given namespace*, null, and *is*. If *will execute script* is true, set the *synchronous custom elements flag*; otherwise, leave it unset.

   Note

   This will cause custom element constructors[p742] to run, if will execute script *is true. However, since we incremented the throw-on-dynamic-markup-insertion counter[p1096], this cannot cause new characters to be inserted into the tokenizer[p1099], or the document to be blown away[p1098].*

10. Append each attribute in the given token to *element*.

    Note

    This can enqueue a custom element callback reaction[p752] for the `attributeChangedCallback`*, which might run immediately (in the next step).*

    Note

    Even though the `is`[p742] *attribute governs the creation of a customized built-in element[p742], it is not present during the execution of the relevant custom element constructor[p742]; it is appended in this step, along with all other attributes.*

11. If *will execute script* is true, then:

    1. Let *queue* be the result of popping from *document*'s relevant agent[p1029]'s custom element reactions stack[p751]. (This will be the same element queue[p751] as was pushed above.)

    2. Invoke custom element reactions[p752] in *queue*.

    3. Decrement *document*'s throw-on-dynamic-markup-insertion counter[p1096].

12. If *element* has an `xmlns` attribute *in the XMLNS namespace* whose value is not exactly the same as the element's namespace, that is a parse error[p1212]. Similarly, if *element* has an `xmlns:xlink` attribute in the XMLNS namespace whose value is not the XLink Namespace, that is a parse error[p1212].

13. If *element* is a resettable element[p505], invoke its reset algorithm[p626]. (This initializes the element's value[p587] and checkedness[p587] based on the element's attributes.)

14. If *element* is a form-associated element[p505] and not a form-associated custom element[p743], the form element pointer[p1228] is not null, there is no `template`[p656] element on the stack of open elements[p1225], *element* is either not listed[p505] or doesn't have a `form`[p588] attribute, and the *intended parent* is in the same tree as the element pointed to by the form element pointer[p1228], then associate[p588] *element* with the `form`[p505] element pointed to by the form element pointer[p1228] and set *element*'s parser inserted flag[p588].

15. Return *element*.

When the steps below require the user agent to **insert a foreign element** for a token in a given namespace, the user agent must run these steps:

1. Let the *adjusted insertion location* be the appropriate place for inserting a node[p1258].

2. Let *element* be the result of creating an element for the token[p1258] in the given namespace, with the intended parent being the element in which the *adjusted insertion location* finds itself.

3. If it is possible to insert *element* at the *adjusted insertion location*, then:

    1. If the parser was not created as part of the HTML fragment parsing algorithm[p1310], then push a new element queue[p751] onto *element*'s relevant agent[p1029]'s custom element reactions stack[p751].

    2. Insert *element* at the *adjusted insertion location*.

    3. If the parser was not created as part of the HTML fragment parsing algorithm[p1310], then pop the element queue[p751] from *element*'s relevant agent[p1029]'s custom element reactions stack[p751], and invoke custom element reactions[p752] in that queue.

    Note

    If the adjusted insertion location *cannot accept more elements, e.g. because it's a* `Document`[p127] *that already has an element child, then* element *is dropped on the floor.*

4. Push *element* onto the stack of open elements[p1225] so that it is the new current node[p1225].

5. Return *element*.

When the steps below require the user agent to **insert an HTML element** for a token, the user agent must insert a foreign element[p1260] for the token, in the HTML namespace.

When the steps below require the user agent to **adjust MathML attributes** for a token, then, if the token has an attribute named `definitionurl`, change its name to `definitionURL` (note the case difference).

When the steps below require the user agent to **adjust SVG attributes** for a token, then, for each attribute on the token whose attribute name is one of the ones in the first column of the following table, change the attribute's name to the name given in the corresponding cell in the second column. (This fixes the case of SVG attributes that are not all lowercase.)

Attribute name on token	Attribute name on element
`attributename`	`attributeName`
`attributetype`	`attributeType`
`basefrequency`	`baseFrequency`
`baseprofile`	`baseProfile`
`calcmode`	`calcMode`
`clippathunits`	`clipPathUnits`
`diffuseconstant`	`diffuseConstant`
`edgemode`	`edgeMode`
`filterunits`	`filterUnits`
`glyphref`	`glyphRef`
`gradienttransform`	`gradientTransform`
`gradientunits`	`gradientUnits`
`kernelmatrix`	`kernelMatrix`
`kernelunitlength`	`kernelUnitLength`
`keypoints`	`keyPoints`

Attribute name on token	Attribute name on element
keysplines	keySplines
keytimes	keyTimes
lengthadjust	lengthAdjust
limitingconeangle	limitingConeAngle
markerheight	markerHeight
markerunits	markerUnits
markerwidth	markerWidth
maskcontentunits	maskContentUnits
maskunits	maskUnits
numoctaves	numOctaves
pathlength	pathLength
patterncontentunits	patternContentUnits
patterntransform	patternTransform
patternunits	patternUnits
pointsatx	pointsAtX
pointsaty	pointsAtY
pointsatz	pointsAtZ
preservealpha	preserveAlpha
preserveaspectratio	preserveAspectRatio
primitiveunits	primitiveUnits
refx	refX
refy	refY
repeatcount	repeatCount
repeatdur	repeatDur
requiredextensions	requiredExtensions
requiredfeatures	requiredFeatures
specularconstant	specularConstant
specularexponent	specularExponent
spreadmethod	spreadMethod
startoffset	startOffset
stddeviation	stdDeviation
stitchtiles	stitchTiles
surfacescale	surfaceScale
systemlanguage	systemLanguage
tablevalues	tableValues
targetx	targetX
targety	targetY
textlength	textLength
viewbox	viewBox
viewtarget	viewTarget
xchannelselector	xChannelSelector
ychannelselector	yChannelSelector
zoomandpan	zoomAndPan

When the steps below require the user agent to **adjust foreign attributes** for a token, then, if any of the attributes on the token match the strings given in the first column of the following table, let the attribute be a namespaced attribute, with the prefix being the string given in the corresponding cell in the second column, the local name being the string given in the corresponding cell in the third column, and the namespace being the namespace given in the corresponding cell in the fourth column. (This fixes the use of namespaced attributes, in particular lang attributes in the XML namespace.)

Attribute name	Prefix	Local name	Namespace
xlink:actuate	xlink	actuate	XLink namespace
xlink:arcrole	xlink	arcrole	XLink namespace
xlink:href	xlink	href	XLink namespace
xlink:role	xlink	role	XLink namespace
xlink:show	xlink	show	XLink namespace

Attribute name	Prefix	Local name	Namespace
xlink:title	xlink	title	XLink namespace
xlink:type	xlink	type	XLink namespace
xml:lang	xml	lang	XML namespace
xml:space	xml	space	XML namespace
xmlns	(none)	xmlns	XMLNS namespace
xmlns:xlink	xmlns	xlink	XMLNS namespace

When the steps below require the user agent to **insert a character** while processing a token, the user agent must run the following steps:

1. Let *data* be the characters passed to the algorithm, or, if no characters were explicitly specified, the character of the character token being processed.
2. Let the *adjusted insertion location* be the appropriate place for inserting a node[p1258].
3. If the *adjusted insertion location* is in a Document[p127] node, then return.

   Note

   The DOM will not let Document[p127] nodes have Text node children, so they are dropped on the floor.

4. If there is a Text node immediately before the *adjusted insertion location*, then append *data* to that Text node's data.

   Otherwise, create a new Text node whose data is *data* and whose node document is the same as that of the element in which the *adjusted insertion location* finds itself, and insert the newly created node at the *adjusted insertion location*.

Example

Here are some sample inputs to the parser and the corresponding number of Text nodes that they result in, assuming a user agent that executes scripts.

Input	Number of Text nodes

`A<script>`
`var script = document.getElementsByTagName('script')[0];`
`document.body.removeChild(script);`
`</script>B`
	One Text node in the document, containing "AB".

`A<script>`
`var text = document.createTextNode('B');`
`document.body.appendChild(text);`
`</script>C`
	Three Text nodes; "A" before the script, the script's contents, and "BC" after the script (the parser appends to the Text node created by the script).

`A<script>`
`var text = document.getElementsByTagName('script')[0].firstChild;`
`text.data = 'B';`
`document.body.appendChild(text);`
`</script>C`
	Two adjacent Text nodes in the document, containing "A" and "BC".

`A<table>B<tr>C</tr>D</table>`	One Text node before the table, containing "ABCD". (This is caused by foster parenting[p1258].)
`A<table><tr> B</tr> C</table>`	One Text node before the table, containing "A B C" (A-space-B-space-C). (This is caused by foster parenting[p1258].)
`A<table><tr> B</tr> </em>C</table>`	One Text node before the table, containing "A BC" (A-space-B-C), and one Text node inside the table (as a child of a tbody[p480]) with a single space character. (Space characters separated from non-space characters by non-character tokens are not affected by foster parenting[p1258], even if those other tokens then get ignored.)

When the steps below require the user agent to **insert a comment** while processing a comment token, optionally with an explicitly insertion position *position*, the user agent must run the following steps:

1. Let *data* be the data given in the comment token being processed.
2. If *position* was specified, then let the *adjusted insertion location* be *position*. Otherwise, let *adjusted insertion location* be the appropriate place for inserting a node[p1258].
3. Create a `Comment` node whose `data` attribute is set to *data* and whose node document is the same as that of the node in which the *adjusted insertion location* finds itself.
4. Insert the newly created node at the *adjusted insertion location*.

DOM mutation events must not fire for changes caused by the UA parsing the document. This includes the parsing of any content inserted using `document.write()`[p1099] and `document.writeln()`[p1099] calls. [UIEVENTS][p1417]

However, mutation observers *do* fire, as required by *DOM* .

13.2.6.2 Parsing elements that contain only text §[p1263]

The **generic raw text element parsing algorithm** and the **generic RCDATA element parsing algorithm** consist of the following steps. These algorithms are always invoked in response to a start tag token.

1. Insert an HTML element[p1260] for the token.
2. If the algorithm that was invoked is the generic raw text element parsing algorithm[p1263], switch the tokenizer to the RAWTEXT state[p1230]; otherwise the algorithm invoked was the generic RCDATA element parsing algorithm[p1263], switch the tokenizer to the RCDATA state[p1230].
3. Let the original insertion mode[p1224] be the current insertion mode[p1224].
4. Then, switch the insertion mode[p1224] to "text[p1280]".

13.2.6.3 Closing elements that have implied end tags §[p1263]

When the steps below require the UA to **generate implied end tags**, then, while the current node[p1225] is a `dd`[p243] element, a `dt`[p242] element, an `li`[p236] element, an `optgroup`[p566] element, an `option`[p567] element, a `p`[p223] element, an `rb`[p1363] element, an `rp`[p272] element, an `rt`[p271] element, or an `rtc`[p1363] element, the UA must pop the current node[p1225] off the stack of open elements[p1225].

If a step requires the UA to generate implied end tags but lists an element to exclude from the process, then the UA must perform the above steps as if that element was not in the above list.

When the steps below require the UA to **generate all implied end tags thoroughly**, then, while the current node[p1225] is a `caption`[p477] element, a `colgroup`[p478] element, a `dd`[p243] element, a `dt`[p242] element, an `li`[p236] element, an `optgroup`[p566] element, an `option`[p567] element, a `p`[p223] element, an `rb`[p1363] element, an `rp`[p272] element, an `rt`[p271] element, an `rtc`[p1363] element, a `tbody`[p480] element, a `td`[p484] element, a `tfoot`[p482] element, a `th`[p486] element, a `thead`[p481] element, or a `tr`[p483] element, the UA must pop the current node[p1225] off the stack of open elements[p1225].

13.2.6.4 The rules for parsing tokens in HTML content §[p1263]

13.2.6.4.1 The "initial" insertion mode §[p1263]

A `Document`[p127] object has an associated **parser cannot change the mode flag** (a boolean). It is initially false.

When the user agent is to apply the rules for the "initial[p1263]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Ignore the token.

↪ **A comment token**

Insert a comment[p1262] as the last child of the `Document`[p127] object.

↪ **A DOCTYPE token**

If the DOCTYPE token's name is not "`html`", or the token's public identifier is not missing, or the token's system identifier is neither missing nor "`about:legacy-compat`[p94]", then there is a parse error[p1212].

Append a `DocumentType` node to the `Document`[p127] node, with its name set to the name given in the DOCTYPE token, or the empty string if the name was missing; its public ID set to the public identifier given in the DOCTYPE token, or the empty string if the public identifier was missing; and its system ID set to the system identifier given in the DOCTYPE token, or the empty string if the system identifier was missing.

Note

This also ensures that the `DocumentType` node is returned as the value of the `doctype` attribute of the `Document`[p127] object.

Then, if the document is *not* an `iframe` `srcdoc` document[p384], and the parser cannot change the mode flag[p1263] is false, and the DOCTYPE token matches one of the conditions in the following list, then set the `Document`[p127] to quirks mode:

- The *force-quirks flag*[p1229] is set to *on*.
- The name is not "`html`".
- The public identifier is set to: "`-//W3O//DTD W3 HTML Strict 3.0//EN//`"
- The public identifier is set to: "`-/W3C/DTD HTML 4.0 Transitional/EN`"
- The public identifier is set to: "`HTML`"
- The system identifier is set to: "`http://www.ibm.com/data/dtd/v11/ibmxhtml1-transitional.dtd`"
- The public identifier starts with: "`+//Silmaril//dtd html Pro v0r11 19970101//`"
- The public identifier starts with: "`-//AS//DTD HTML 3.0 asWedit + extensions//`"
- The public identifier starts with: "`-//AdvaSoft Ltd//DTD HTML 3.0 asWedit + extensions//`"
- The public identifier starts with: "`-//IETF//DTD HTML 2.0 Level 1//`"
- The public identifier starts with: "`-//IETF//DTD HTML 2.0 Level 2//`"
- The public identifier starts with: "`-//IETF//DTD HTML 2.0 Strict Level 1//`"
- The public identifier starts with: "`-//IETF//DTD HTML 2.0 Strict Level 2//`"
- The public identifier starts with: "`-//IETF//DTD HTML 2.0 Strict//`"
- The public identifier starts with: "`-//IETF//DTD HTML 2.0//`"
- The public identifier starts with: "`-//IETF//DTD HTML 2.1E//`"
- The public identifier starts with: "`-//IETF//DTD HTML 3.0//`"
- The public identifier starts with: "`-//IETF//DTD HTML 3.2 Final//`"
- The public identifier starts with: "`-//IETF//DTD HTML 3.2//`"
- The public identifier starts with: "`-//IETF//DTD HTML 3//`"
- The public identifier starts with: "`-//IETF//DTD HTML Level 0//`"
- The public identifier starts with: "`-//IETF//DTD HTML Level 1//`"
- The public identifier starts with: "`-//IETF//DTD HTML Level 2//`"
- The public identifier starts with: "`-//IETF//DTD HTML Level 3//`"
- The public identifier starts with: "`-//IETF//DTD HTML Strict Level 0//`"
- The public identifier starts with: "`-//IETF//DTD HTML Strict Level 1//`"
- The public identifier starts with: "`-//IETF//DTD HTML Strict Level 2//`"
- The public identifier starts with: "`-//IETF//DTD HTML Strict Level 3//`"
- The public identifier starts with: "`-//IETF//DTD HTML Strict//`"
- The public identifier starts with: "`-//IETF//DTD HTML//`"
- The public identifier starts with: "`-//Metrius//DTD Metrius Presentational//`"
- The public identifier starts with: "`-//Microsoft//DTD Internet Explorer 2.0 HTML Strict//`"
- The public identifier starts with: "`-//Microsoft//DTD Internet Explorer 2.0 HTML//`"
- The public identifier starts with: "`-//Microsoft//DTD Internet Explorer 2.0 Tables//`"
- The public identifier starts with: "`-//Microsoft//DTD Internet Explorer 3.0 HTML Strict//`"
- The public identifier starts with: "`-//Microsoft//DTD Internet Explorer 3.0 HTML//`"
- The public identifier starts with: "`-//Microsoft//DTD Internet Explorer 3.0 Tables//`"
- The public identifier starts with: "`-//Netscape Comm. Corp.//DTD HTML//`"
- The public identifier starts with: "`-//Netscape Comm. Corp.//DTD Strict HTML//`"
- The public identifier starts with: "`-//O'Reilly and Associates//DTD HTML 2.0//`"
- The public identifier starts with: "`-//O'Reilly and Associates//DTD HTML Extended 1.0//`"
- The public identifier starts with: "`-//O'Reilly and Associates//DTD HTML Extended Relaxed 1.0//`"
- The public identifier starts with: "`-//SQ//DTD HTML 2.0 HoTMetaL + extensions//`"
- The public identifier starts with: "`-//SoftQuad Software//DTD HoTMetaL PRO 6.0::19990601::extensions to HTML 4.0//`"
- The public identifier starts with: "`-//SoftQuad//DTD HoTMetaL PRO 4.0::19971010::extensions to HTML 4.0//`"
- The public identifier starts with: "`-//Spyglass//DTD HTML 2.0 Extended//`"
- The public identifier starts with: "`-//Sun Microsystems Corp.//DTD HotJava HTML//`"
- The public identifier starts with: "`-//Sun Microsystems Corp.//DTD HotJava Strict HTML//`"
- The public identifier starts with: "`-//W3C//DTD HTML 3 1995-03-24//`"
- The public identifier starts with: "`-//W3C//DTD HTML 3.2 Draft//`"
- The public identifier starts with: "`-//W3C//DTD HTML 3.2 Final//`"
- The public identifier starts with: "`-//W3C//DTD HTML 3.2//`"
- The public identifier starts with: "`-//W3C//DTD HTML 3.2S Draft//`"
- The public identifier starts with: "`-//W3C//DTD HTML 4.0 Frameset//`"
- The public identifier starts with: "`-//W3C//DTD HTML 4.0 Transitional//`"
- The public identifier starts with: "`-//W3C//DTD HTML Experimental 19960712//`"
- The public identifier starts with: "`-//W3C//DTD HTML Experimental 970421//`"
- The public identifier starts with: "`-//W3C//DTD W3 HTML//`"
- The public identifier starts with: "`-//W3O//DTD W3 HTML 3.0//`"
- The public identifier starts with: "`-//WebTechs//DTD Mozilla HTML 2.0//`"
- The public identifier starts with: "`-//WebTechs//DTD Mozilla HTML//`"

- The system identifier is missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Frameset//"
- The system identifier is missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Transitional//"

Otherwise, if the document is *not* an iframe srcdoc document[p384], and the parser cannot change the mode flag[p1263] is false, and the DOCTYPE token matches one of the conditions in the following list, then then set the Document[p127] to limited-quirks mode:

- The public identifier starts with: "-//W3C//DTD XHTML 1.0 Frameset//"
- The public identifier starts with: "-//W3C//DTD XHTML 1.0 Transitional//"
- The system identifier is not missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Frameset//"
- The system identifier is not missing and the public identifier starts with: "-//W3C//DTD HTML 4.01 Transitional//"

The system identifier and public identifier strings must be compared to the values given in the lists above in an ASCII case-insensitive manner. A system identifier whose value is the empty string is not considered missing for the purposes of the conditions above.

Then, switch the insertion mode[p1224] to "before html[p1265]".

↪ **Anything else**

If the document is *not* an iframe srcdoc document[p384], then this is a parse error[p1212]; if the parser cannot change the mode flag[p1263] is false, set the Document[p127] to quirks mode.

In any case, switch the insertion mode[p1224] to "before html[p1265]", then reprocess the token.

13.2.6.4.2 The "before html" insertion mode §[p1265]

When the user agent is to apply the rules for the "before html[p1265]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A comment token**

Insert a comment[p1262] as the last child of the Document[p127] object.

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Ignore the token.

↪ **A start tag whose tag name is "html"**

Create an element for the token[p1258] in the HTML namespace, with the Document[p127] as the intended parent. Append it to the Document[p127] object. Put this element in the stack of open elements[p1225].

Switch the insertion mode[p1224] to "before head[p1266]".

↪ **An end tag whose tag name is one of: "head", "body", "html", "br"**

Act as described in the "anything else" entry below.

↪ **Any other end tag**

Parse error[p1212]. Ignore the token.

↪ **Anything else**

Create an html[p167] element whose node document is the Document[p127] object. Append it to the Document[p127] object. Put this element in the stack of open elements[p1225].

Switch the insertion mode[p1224] to "before head[p1266]", then reprocess the token.

The document element can end up being removed from the Document[p127] object, e.g. by scripts; nothing in particular happens in such cases, content continues being appended to the nodes as described in the next section.

13.2.6.4.3 The "before head" insertion mode §[p1266]

When the user agent is to apply the rules for the "before head[p1266]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Ignore the token.

↪ **A comment token**

Insert a comment[p1262].

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **A start tag whose tag name is "head"**

Insert an HTML element[p1260] for the token.

Set the head element pointer[p1228] to the newly created head[p168] element.

Switch the insertion mode[p1224] to "in head[p1266]".

↪ **An end tag whose tag name is one of: "head", "body", "html", "br"**

Act as described in the "anything else" entry below.

↪ **Any other end tag**

Parse error[p1212]. Ignore the token.

↪ **Anything else**

Insert an HTML element[p1260] for a "head" start tag token with no attributes.

Set the head element pointer[p1228] to the newly created head[p168] element.

Switch the insertion mode[p1224] to "in head[p1266]".

Reprocess the current token.

13.2.6.4.4 The "in head" insertion mode §[p1266]

When the user agent is to apply the rules for the "in head[p1266]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Insert the character[p1262].

↪ **A comment token**

Insert a comment[p1262].

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **A start tag whose tag name is one of: "base", "basefont", "bgsound", "link"**

Insert an HTML element[p1260] for the token. Immediately pop the current node[p1225] off the stack of open elements[p1225].

Acknowledge the token's *self-closing flag*[p1229], if it is set.

↪ **A start tag whose tag name is "meta"**

Insert an HTML element[p1260] for the token. Immediately pop the current node[p1225] off the stack of open elements[p1225].

Acknowledge the token's *self-closing flag*[p1229], if it is set.

If the active speculative HTML parser[p1298] is null, then:

1. If the element has a `charset`[p185] attribute, and getting an encoding from its value results in an encoding, and the confidence[p1217] is currently *tentative*, then change the encoding[p1223] to the resulting encoding.

2. Otherwise, if the element has an `http-equiv`[p190] attribute whose value is an ASCII case-insensitive match for the string "`Content-Type`", and the element has a `content`[p185] attribute, and applying the algorithm for extracting a character encoding from a `meta` element[p96] to that attribute's value returns an encoding, and the confidence[p1217] is currently *tentative*, then change the encoding[p1223] to the extracted encoding.

Note

The speculative HTML parser[p1298] doesn't speculatively apply character encoding declarations in order to reduce implementation complexity.

↪ **A start tag whose tag name is "title"**

Follow the generic RCDATA element parsing algorithm[p1263].

↪ **A start tag whose tag name is "noscript", if the scripting flag[p1228] is enabled**

↪ **A start tag whose tag name is one of: "noframes", "style"**

Follow the generic raw text element parsing algorithm[p1263].

↪ **A start tag whose tag name is "noscript", if the scripting flag[p1228] is disabled**

Insert an HTML element[p1260] for the token.

Switch the insertion mode[p1224] to "in head noscript[p1268]".

↪ **A start tag whose tag name is "script"**

Run these steps:

1. Let the *adjusted insertion location* be the appropriate place for inserting a node[p1258].

2. Create an element for the token[p1258] in the HTML namespace, with the intended parent being the element in which the *adjusted insertion location* finds itself.

3. Set the element's parser document[p645] to the `Document`[p127], and set the element's force async[p645] to false.

   Note

   This ensures that, if the script is external, any `document.write()`[p1099] calls in the script will execute in-line, instead of blowing the document away, as would happen in most other cases. It also prevents the script from executing until the end tag is seen.

4. If the parser was created as part of the HTML fragment parsing algorithm[p1310], then set the `script`[p638] element's already started[p645] to true. (fragment case[p1311])

5. If the parser was invoked via the `document.write()`[p1099] or `document.writeln()`[p1099] methods, then optionally set the `script`[p638] element's already started[p645] to true. (For example, the user agent might use this clause to prevent execution of cross-origin[p869] scripts inserted via `document.write()`[p1099] under slow network conditions, or when the page has already taken a long time to load.)

6. Insert the newly created element at the *adjusted insertion location*.

7. Push the element onto the stack of open elements[p1225] so that it is the new current node[p1225].

8. Switch the tokenizer to the script data state[p1230].

9. Let the original insertion mode[p1224] be the current insertion mode[p1224].

10. Switch the insertion mode[p1224] to "text[p1280]".

↪ **An end tag whose tag name is "head"**

Pop the current node[p1225] (which will be the head[p168] element) off the stack of open elements[p1225].

Switch the insertion mode[p1224] to "after head[p1269]".

↪ **An end tag whose tag name is one of: "body", "html", "br"**

Act as described in the "anything else" entry below.

↪ **A start tag whose tag name is "template"**

Insert an HTML element[p1260] for the token.

Insert a marker[p1227] at the end of the list of active formatting elements[p1227].

Set the frameset-ok flag[p1228] to "not ok".

Switch the insertion mode[p1224] to "in template[p1290]".

Push "in template[p1290]" onto the stack of template insertion modes[p1224] so that it is the new current template insertion mode[p1224].

↪ **An end tag whose tag name is "template"**

If there is no `template`[p656] element on the stack of open elements[p1225], then this is a parse error[p1212]; ignore the token.

Otherwise, run these steps:

1. Generate all implied end tags thoroughly[p1263].
2. If the current node[p1225] is not a `template`[p656] element, then this is a parse error[p1212].
3. Pop elements from the stack of open elements[p1225] until a `template`[p656] element has been popped from the stack.
4. Clear the list of active formatting elements up to the last marker[p1228].
5. Pop the current template insertion mode[p1224] off the stack of template insertion modes[p1224].
6. Reset the insertion mode appropriately[p1224].

↪ **A start tag whose tag name is "head"**

↪ **Any other end tag**

Parse error[p1212]. Ignore the token.

↪ **Anything else**

Pop the current node[p1225] (which will be the head[p168] element) off the stack of open elements[p1225].

Switch the insertion mode[p1224] to "after head[p1269]".

Reprocess the token.

13.2.6.4.5 The "in head noscript" insertion mode §[p1268]

When the user agent is to apply the rules for the "in head noscript[p1268]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **An end tag whose tag name is "noscript"**

Pop the current node[p1225] (which will be a `noscript`[p654] element) from the stack of open elements[p1225]; the new current node[p1225] will be a head[p168] element.

Switch the insertion mode[p1224] to "in head[p1266]".

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

↪ **A comment token**

↪ **A start tag whose tag name is one of: "basefont", "bgsound", "link", "meta", "noframes", "style"**

Process the token using the rules for[p1224] the "in head[p1266]" insertion mode[p1224].

↪ **An end tag whose tag name is "br"**

Act as described in the "anything else" entry below.

↪ **A start tag whose tag name is one of: "head", "noscript"**

↪ **Any other end tag**

Parse error[p1212]. Ignore the token.

↪ **Anything else**

Parse error[p1212].

Pop the current node[p1225] (which will be a `noscript`[p654] element) from the stack of open elements[p1225]; the new current node[p1225] will be a `head`[p168] element.

Switch the insertion mode[p1224] to "in head[p1266]".

Reprocess the token.

13.2.6.4.6 The "after head" insertion mode §[p1269]

When the user agent is to apply the rules for the "after head[p1269]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Insert the character[p1262].

↪ **A comment token**

Insert a comment[p1262].

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **A start tag whose tag name is "body"**

Insert an HTML element[p1260] for the token.

Set the frameset-ok flag[p1228] to "not ok".

Switch the insertion mode[p1224] to "in body[p1270]".

↪ **A start tag whose tag name is "frameset"**

Insert an HTML element[p1260] for the token.

Switch the insertion mode[p1224] to "in frameset[p1292]".

↪ **A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"**

Parse error[p1212].

Push the node pointed to by the head element pointer[p1228] onto the stack of open elements[p1225].

Process the token using the rules for[p1224] the "in head[p1266]" insertion mode[p1224].

Remove the node pointed to by the head element pointer[p1228] from the stack of open elements[p1225]. (It might not be the current node[p1225] at this point.)

> **Note**
> *The head element pointer[p1228] cannot be null at this point.*

↪ **An end tag whose tag name is "template"**

Process the token using the rules for[p1224] the "in head[p1266]" insertion mode[p1224].

↪ **An end tag whose tag name is one of: "body", "html", "br"**

Act as described in the "anything else" entry below.

↪ **A start tag whose tag name is "head"**

↪ **Any other end tag**

Parse error[p1212]. Ignore the token.

↪ **Anything else**

Insert an HTML element[p1260] for a "body" start tag token with no attributes.

Switch the insertion mode[p1224] to "in body[p1270]".

Reprocess the current token.

13.2.6.4.7 The "in body" insertion mode §[p1270]

When the user agent is to apply the rules for the "in body[p1270]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token that is U+0000 NULL**

Parse error[p1212]. Ignore the token.

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Reconstruct the active formatting elements[p1227], if any.

Insert the token's character[p1262].

↪ **Any other character token**

Reconstruct the active formatting elements[p1227], if any.

Insert the token's character[p1262].

Set the frameset-ok flag[p1228] to "not ok".

↪ **A comment token**

Insert a comment[p1262].

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is "html"**

Parse error[p1212].

If there is a `template`[p656] element on the stack of open elements[p1225], then ignore the token.

Otherwise, for each attribute on the token, check to see if the attribute is already present on the top element of the stack of open elements[p1225]. If it is not, add the attribute and its corresponding value to that element.

↪ **A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style",**

"template", "title"

↪ **An end tag whose tag name is "template"**

Process the token using the rules for[p1224] the "in head[p1266]" insertion mode[p1224].

↪ **A start tag whose tag name is "body"**

Parse error[p1212].

If the second element on the stack of open elements[p1225] is not a body[p199] element, if the stack of open elements[p1225] has only one node on it, or if there is a template[p656] element on the stack of open elements[p1225], then ignore the token. (fragment case[p1311])

Otherwise, set the frameset-ok flag[p1228] to "not ok"; then, for each attribute on the token, check to see if the attribute is already present on the body[p199] element (the second element) on the stack of open elements[p1225], and if it is not, add the attribute and its corresponding value to that element.

↪ **A start tag whose tag name is "frameset"**

Parse error[p1212].

If the stack of open elements[p1225] has only one node on it, or if the second element on the stack of open elements[p1225] is not a body[p199] element, then ignore the token. (fragment case[p1311])

If the frameset-ok flag[p1228] is set to "not ok", ignore the token.

Otherwise, run the following steps:

1. Remove the second element on the stack of open elements[p1225] from its parent node, if it has one.
2. Pop all the nodes from the bottom of the stack of open elements[p1225], from the current node[p1225] up to, but not including, the root html[p167] element.
3. Insert an HTML element[p1260] for the token.
4. Switch the insertion mode[p1224] to "in frameset[p1292]".

↪ **An end-of-file token**

If the stack of template insertion modes[p1224] is not empty, then process the token using the rules for[p1224] the "in template[p1290]" insertion mode[p1224].

Otherwise, follow these steps:

1. If there is a node in the stack of open elements[p1225] that is not either a dd[p243] element, a dt[p242] element, an li[p236] element, an optgroup[p566] element, an option[p567] element, a p[p223] element, an rb[p1363] element, an rp[p272] element, an rt[p271] element, an rtc[p1363] element, a tbody[p480] element, a td[p484] element, a tfoot[p482] element, a th[p486] element, a thead[p481] element, a tr[p483] element, the body[p199] element, or the html[p167] element, then this is a parse error[p1212].
2. Stop parsing[p1296].

↪ **An end tag whose tag name is "body"**

If the stack of open elements[p1225] does not have a body element in scope[p1226], this is a parse error[p1212]; ignore the token.

Otherwise, if there is a node in the stack of open elements[p1225] that is not either a dd[p243] element, a dt[p242] element, an li[p236] element, an optgroup[p566] element, an option[p567] element, a p[p223] element, an rb[p1363] element, an rp[p272] element, an rt[p271] element, an rtc[p1363] element, a tbody[p480] element, a td[p484] element, a tfoot[p482] element, a th[p486] element, a thead[p481] element, a tr[p483] element, the body[p199] element, or the html[p167] element, then this is a parse error[p1212].

Switch the insertion mode[p1224] to "after body[p1291]".

↪ **An end tag whose tag name is "html"**

If the stack of open elements[p1225] does not have a body element in scope[p1226], this is a parse error[p1212]; ignore the token.

Otherwise, if there is a node in the stack of open elements[p1225] that is not either a dd[p243] element, a dt[p242] element, an li[p236] element, an optgroup[p566] element, an option[p567] element, a p[p223] element, an rb[p1363] element, an rp[p272] element, an rt[p271] element, an rtc[p1363] element, a tbody[p480] element, a td[p484] element, a tfoot[p482] element, a th[p486] element, a thead[p481] element, a tr[p483] element, the body[p199] element, or the html[p167] element, then this is a parse error[p1212].

Switch the insertion mode[p1224] to "after body[p1291]".

Reprocess the token.

↪ **A start tag whose tag name is one of: "address", "article", "aside", "blockquote", "center", "details", "dialog", "dir", "div", "dl", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "main", "menu", "nav", "ol", "p", "search", "section", "summary", "ul"**

If the stack of open elements[p1225] has a p element in button scope[p1227], then close a p element[p1278].

Insert an HTML element[p1260] for the token.

↪ **A start tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"**

If the stack of open elements[p1225] has a p element in button scope[p1227], then close a p element[p1278].

If the current node[p1225] is an HTML element[p45] whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a parse error[p1212]; pop the current node[p1225] off the stack of open elements[p1225].

Insert an HTML element[p1260] for the token.

↪ **A start tag whose tag name is one of: "pre", "listing"**

If the stack of open elements[p1225] has a p element in button scope[p1227], then close a p element[p1278].

Insert an HTML element[p1260] for the token.

If the next token[p1257] is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one. (Newlines at the start of `pre`[p228] blocks are ignored as an authoring convenience.)

Set the frameset-ok flag[p1228] to "not ok".

↪ **A start tag whose tag name is "form"**

If the `form` element pointer[p1228] is not null, and there is no `template`[p656] element on the stack of open elements[p1225], then this is a parse error[p1212]; ignore the token.

Otherwise:

If the stack of open elements[p1225] has a p element in button scope[p1227], then close a p element[p1278].

Insert an HTML element[p1260] for the token, and, if there is no `template`[p656] element on the stack of open elements[p1225], set the `form` element pointer[p1228] to point to the element created.

↪ **A start tag whose tag name is "li"**

Run these steps:

1. Set the frameset-ok flag[p1228] to "not ok".
2. Initialize *node* to be the current node[p1225] (the bottommost node of the stack).
3. *Loop*: If *node* is an `li`[p236] element, then run these substeps:
    1. Generate implied end tags[p1263], except for `li`[p236] elements.
    2. If the current node[p1225] is not an `li`[p236] element, then this is a parse error[p1212].
    3. Pop elements from the stack of open elements[p1225] until an `li`[p236] element has been popped from the stack.
    4. Jump to the step labeled *done* below.
4. If *node* is in the special[p1226] category, but is not an `address`[p217], `div`[p251], or `p`[p223] element, then jump to the step labeled *done* below.
5. Otherwise, set *node* to the previous entry in the stack of open elements[p1225] and return to the step labeled *loop*.
6. *Done*: If the stack of open elements[p1225] has a p element in button scope[p1227], then close a p element[p1278].
7. Finally, insert an HTML element[p1260] for the token.

↪ **A start tag whose tag name is one of: "dd", "dt"**

Run these steps:

1. Set the frameset-ok flag[p1228] to "not ok".
2. Initialize *node* to be the current node[p1225] (the bottommost node of the stack).
3. *Loop*: If *node* is a `dd`[p243] element, then run these substeps:
    1. Generate implied end tags[p1263], except for `dd`[p243] elements.
    2. If the current node[p1225] is not a `dd`[p243] element, then this is a parse error[p1212].
    3. Pop elements from the stack of open elements[p1225] until a `dd`[p243] element has been popped from the stack.
    4. Jump to the step labeled *done* below.
4. If *node* is a `dt`[p242] element, then run these substeps:
    1. Generate implied end tags[p1263], except for `dt`[p242] elements.
    2. If the current node[p1225] is not a `dt`[p242] element, then this is a parse error[p1212].
    3. Pop elements from the stack of open elements[p1225] until a `dt`[p242] element has been popped from the stack.
    4. Jump to the step labeled *done* below.
5. If *node* is in the special[p1226] category, but is not an `address`[p217], `div`[p251], or `p`[p223] element, then jump to the step labeled *done* below.
6. Otherwise, set *node* to the previous entry in the stack of open elements[p1225] and return to the step labeled *loop*.
7. *Done*: If the stack of open elements[p1225] has a `p` element in button scope[p1227], then close a `p` element[p1278].
8. Finally, insert an HTML element[p1260] for the token.

↪ **A start tag whose tag name is "plaintext"**

If the stack of open elements[p1225] has a `p` element in button scope[p1227], then close a `p` element[p1278].

Insert an HTML element[p1260] for the token.

Switch the tokenizer to the PLAINTEXT state[p1231].

Note

Once a start tag with the tag name "plaintext" has been seen, that will be the last token ever seen other than character tokens (and the end-of-file token), because there is no way to switch out of the PLAINTEXT state[p1231].

↪ **A start tag whose tag name is "button"**

1. If the stack of open elements[p1225] has a `button` element in scope[p1226], then run these substeps:
    1. Parse error[p1212].
    2. Generate implied end tags[p1263].
    3. Pop elements from the stack of open elements[p1225] until a `button`[p556] element has been popped from the stack.
2. Reconstruct the active formatting elements[p1227], if any.
3. Insert an HTML element[p1260] for the token.
4. Set the frameset-ok flag[p1228] to "not ok".

↪ **An end tag whose tag name is one of: "address", "article", "aside", "blockquote", "button", "center", "details", "dialog", "dir", "div", "dl", "fieldset", "figcaption", "figure", "footer", "header", "hgroup", "listing", "main", "menu", "nav", "ol", "pre", "search", "section", "summary", "ul"**

If the stack of open elements[p1225] does not have an element in scope[p1226] that is an HTML element[p45] with the same tag name as that of the token, then this is a parse error[p1212]; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags[p1263].
2. If the current node[p1225] is not an HTML element[p45] with the same tag name as that of the token, then this is a parse error[p1212].
3. Pop elements from the stack of open elements[p1225] until an HTML element[p45] with the same tag name as the token has been popped from the stack.

↪ **An end tag whose tag name is "form"**

If there is no `template`[p656] element on the stack of open elements[p1225], then run these substeps:

1. Let *node* be the element that the `form` element pointer[p1228] is set to, or null if it is not set to an element.
2. Set the `form` element pointer[p1228] to null.
3. If *node* is null or if the stack of open elements[p1225] does not have *node* in scope[p1226], then this is a parse error[p1212]; return and ignore the token.
4. Generate implied end tags[p1263].
5. If the current node[p1225] is not *node*, then this is a parse error[p1212].
6. Remove *node* from the stack of open elements[p1225].

If there *is* a `template`[p656] element on the stack of open elements[p1225], then run these substeps instead:

1. If the stack of open elements[p1225] does not have a `form` element in scope[p1226], then this is a parse error[p1212]; return and ignore the token.
2. Generate implied end tags[p1263].
3. If the current node[p1225] is not a `form`[p505] element, then this is a parse error[p1212].
4. Pop elements from the stack of open elements[p1225] until a `form`[p505] element has been popped from the stack.

↪ **An end tag whose tag name is "p"**

If the stack of open elements[p1225] does not have a `p` element in button scope[p1227], then this is a parse error[p1212]; insert an HTML element[p1260] for a "p" start tag token with no attributes.

Close a `p` element[p1278].

↪ **An end tag whose tag name is "li"**

If the stack of open elements[p1225] does not have an `li` element in list item scope[p1227], then this is a parse error[p1212]; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags[p1263], except for `li`[p236] elements.
2. If the current node[p1225] is not an `li`[p236] element, then this is a parse error[p1212].
3. Pop elements from the stack of open elements[p1225] until an `li`[p236] element has been popped from the stack.

↪ **An end tag whose tag name is one of: "dd", "dt"**

If the stack of open elements[p1225] does not have an element in scope[p1226] that is an HTML element[p45] with the same tag name as that of the token, then this is a parse error[p1212]; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags[p1263], except for HTML elements[p45] with the same tag name as the token.
2. If the current node[p1225] is not an HTML element[p45] with the same tag name as that of the token, then this is a parse error[p1212].
3. Pop elements from the stack of open elements[p1225] until an HTML element[p45] with the same tag name as the token has been popped from the stack.

↪ **An end tag whose tag name is one of: "h1", "h2", "h3", "h4", "h5", "h6"**

If the stack of open elements[p1225] does not have an element in scope[p1226] that is an HTML element[p45] and whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6", then this is a parse error[p1212]; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags[p1263].
2. If the current node[p1225] is not an HTML element[p45] with the same tag name as that of the token, then this is a parse error[p1212].
3. Pop elements from the stack of open elements[p1225] until an HTML element[p45] whose tag name is one of "h1", "h2", "h3", "h4", "h5", or "h6" has been popped from the stack.

↪ **An end tag whose tag name is "sarcasm"**

Take a deep breath, then act as described in the "any other end tag" entry below.

↪ **A start tag whose tag name is "a"**

If the list of active formatting elements[p1227] contains an a[p252] element between the end of the list and the last marker[p1227] on the list (or the start of the list if there is no marker[p1227] on the list), then this is a parse error[p1212]; run the adoption agency algorithm[p1278] for the token, then remove that element from the list of active formatting elements[p1227] and the stack of open elements[p1225] if the adoption agency algorithm[p1278] didn't already remove it (it might not have if the element is not in table scope[p1227]).

Example

In the non-conforming stream `<a href="a">a<table><a href="b">b</table>x`, the first a[p252] element would be closed upon seeing the second one, and the "x" character would be inside a link to "b", not to "a". This is despite the fact that the outer a[p252] element is not in table scope (meaning that a regular `</a>` end tag at the start of the table wouldn't close the outer a[p252] element). The result is that the two a[p252] elements are indirectly nested inside each other — non-conforming markup will often result in non-conforming DOMs when parsed.

Reconstruct the active formatting elements[p1227], if any.

Insert an HTML element[p1260] for the token. Push onto the list of active formatting elements[p1227] that element.

↪ **A start tag whose tag name is one of: "b", "big", "code", "em", "font", "i", "s", "small", "strike", "strong", "tt", "u"**

Reconstruct the active formatting elements[p1227], if any.

Insert an HTML element[p1260] for the token. Push onto the list of active formatting elements[p1227] that element.

↪ **A start tag whose tag name is "nobr"**

Reconstruct the active formatting elements[p1227], if any.

If the stack of open elements[p1225] has a `nobr` element in scope[p1226], then this is a parse error[p1212]; run the adoption agency algorithm[p1278] for the token, then once again reconstruct the active formatting elements[p1227], if any.

Insert an HTML element[p1260] for the token. Push onto the list of active formatting elements[p1227] that element.

↪ **An end tag whose tag name is one of: "a", "b", "big", "code", "em", "font", "i", "nobr", "s", "small", "strike", "strong", "tt", "u"**

Run the adoption agency algorithm[p1278] for the token.

↪ **A start tag whose tag name is one of: "applet", "marquee", "object"**

Reconstruct the active formatting elements[p1227], if any.

Insert an HTML element[p1260] for the token.

Insert a marker[p1227] at the end of the list of active formatting elements[p1227].

Set the frameset-ok flag[p1228] to "not ok".

↪ **An end tag token whose tag name is one of: "applet", "marquee", "object"**

If the stack of open elements[p1225] does not have an element in scope[p1226] that is an HTML element[p45] with the same tag name as

that of the token, then this is a parse error[p1212]; ignore the token.

Otherwise, run these steps:

1. Generate implied end tags[p1263].
2. If the current node[p1225] is not an HTML element[p45] with the same tag name as that of the token, then this is a parse error[p1212].
3. Pop elements from the stack of open elements[p1225] until an HTML element[p45] with the same tag name as the token has been popped from the stack.
4. Clear the list of active formatting elements up to the last marker[p1228].

↪ **A start tag whose tag name is "table"**

If the `Document`[p127] is *not* set to quirks mode, and the stack of open elements[p1225] has a `p` element in button scope[p1227], then close a `p` element[p1278].

Insert an HTML element[p1260] for the token.

Set the frameset-ok flag[p1228] to "not ok".

Switch the insertion mode[p1224] to "in table[p1281]".

↪ **An end tag whose tag name is "br"**

Parse error[p1212]. Drop the attributes from the token, and act as described in the next entry; i.e. act as if this was a "br" start tag token with no attributes, rather than the end tag token that it actually is.

↪ **A start tag whose tag name is one of: "area", "br", "embed", "img", "keygen", "wbr"**

Reconstruct the active formatting elements[p1227], if any.

Insert an HTML element[p1260] for the token. Immediately pop the current node[p1225] off the stack of open elements[p1225].

Acknowledge the token's *self-closing flag*[p1229], if it is set.

Set the frameset-ok flag[p1228] to "not ok".

↪ **A start tag whose tag name is "input"**

Reconstruct the active formatting elements[p1227], if any.

Insert an HTML element[p1260] for the token. Immediately pop the current node[p1225] off the stack of open elements[p1225].

Acknowledge the token's *self-closing flag*[p1229], if it is set.

If the token does not have an attribute with the name "type", or if it does, but that attribute's value is not an ASCII case-insensitive match for the string "`hidden`", then: set the frameset-ok flag[p1228] to "not ok".

↪ **A start tag whose tag name is one of: "param", "source", "track"**

Insert an HTML element[p1260] for the token. Immediately pop the current node[p1225] off the stack of open elements[p1225].

Acknowledge the token's *self-closing flag*[p1229], if it is set.

↪ **A start tag whose tag name is "hr"**

If the stack of open elements[p1225] has a `p` element in button scope[p1227], then close a `p` element[p1278].

Insert an HTML element[p1260] for the token. Immediately pop the current node[p1225] off the stack of open elements[p1225].

Acknowledge the token's *self-closing flag*[p1229], if it is set.

Set the frameset-ok flag[p1228] to "not ok".

↪ **A start tag whose tag name is "image"**

Parse error[p1212]. Change the token's tag name to "img" and reprocess it. (Don't ask.)

↪ **A start tag whose tag name is "textarea"**

Run these steps:

1. Insert an HTML element[p1260] for the token.
2. If the next token[p1257] is a U+000A LINE FEED (LF) character token, then ignore that token and move on to the next one. (Newlines at the start of `textarea`[p570] elements are ignored as an authoring convenience.)
3. Switch the tokenizer to the RCDATA state[p1230].
4. Let the original insertion mode[p1224] be the current insertion mode[p1224].
5. Set the frameset-ok flag[p1228] to "not ok".
6. Switch the insertion mode[p1224] to "text[p1280]".

↪ **A start tag whose tag name is "xmp"**

If the stack of open elements[p1225] has a `p` element in button scope[p1227], then close a `p` element[p1278].

Reconstruct the active formatting elements[p1227], if any.

Set the frameset-ok flag[p1228] to "not ok".

Follow the generic raw text element parsing algorithm[p1263].

↪ **A start tag whose tag name is "iframe"**

Set the frameset-ok flag[p1228] to "not ok".

Follow the generic raw text element parsing algorithm[p1263].

↪ **A start tag whose tag name is "noembed"**

↪ **A start tag whose tag name is "noscript", if the scripting flag[p1228] is enabled**

Follow the generic raw text element parsing algorithm[p1263].

↪ **A start tag whose tag name is "select"**

Reconstruct the active formatting elements[p1227], if any.

Insert an HTML element[p1260] for the token.

Set the frameset-ok flag[p1228] to "not ok".

If the insertion mode[p1224] is one of "in table[p1281]", "in caption[p1284]", "in table body[p1285]", "in row[p1286]", or "in cell[p1287]", then switch the insertion mode[p1224] to "in select in table[p1290]". Otherwise, switch the insertion mode[p1224] to "in select[p1288]".

↪ **A start tag whose tag name is one of: "optgroup", "option"**

If the current node[p1225] is an `option`[p567] element, then pop the current node[p1225] off the stack of open elements[p1225].

Reconstruct the active formatting elements[p1227], if any.

Insert an HTML element[p1260] for the token.

↪ **A start tag whose tag name is one of: "rb", "rtc"**

If the stack of open elements[p1225] has a `ruby` element in scope[p1226], then generate implied end tags[p1263]. If the current node[p1225] is not now a `ruby`[p265] element, this is a parse error[p1212].

Insert an HTML element[p1260] for the token.

↪ **A start tag whose tag name is one of: "rp", "rt"**

If the stack of open elements[p1225] has a `ruby` element in scope[p1226], then generate implied end tags[p1263], except for `rtc`[p1363] elements. If the current node[p1225] is not now a `rtc`[p1363] element or a `ruby`[p265] element, this is a parse error[p1212].

Insert an HTML element[p1260] for the token.

↪ **A start tag whose tag name is "math"**

Reconstruct the active formatting elements[p1227], if any.

Adjust MathML attributes[p1260] for the token. (This fixes the case of MathML attributes that are not all lowercase.)

Adjust foreign attributes[p1261] for the token. (This fixes the use of namespaced attributes, in particular XLink.)

Insert a foreign element[p1260] for the token, in the MathML namespace.

If the token has its *self-closing flag*[p1229] set, pop the current node[p1225] off the stack of open elements[p1225] and acknowledge the token's *self-closing flag*[p1229].

↪ **A start tag whose tag name is "svg"**

Reconstruct the active formatting elements[p1227], if any.

Adjust SVG attributes[p1260] for the token. (This fixes the case of SVG attributes that are not all lowercase.)

Adjust foreign attributes[p1261] for the token. (This fixes the use of namespaced attributes, in particular XLink in SVG.)

Insert a foreign element[p1260] for the token, in the SVG namespace.

If the token has its *self-closing flag*[p1229] set, pop the current node[p1225] off the stack of open elements[p1225] and acknowledge the token's *self-closing flag*[p1229].

↪ **A start tag whose tag name is one of: "caption", "col", "colgroup", "frame", "head", "tbody", "td", "tfoot", "th", "thead", "tr"**

Parse error[p1212]. Ignore the token.

↪ **Any other start tag**

Reconstruct the active formatting elements[p1227], if any.

Insert an HTML element[p1260] for the token.

Note

This element will be an ordinary[p1226] element.

↪ **Any other end tag**

Run these steps:

1. Initialize *node* to be the current node[p1225] (the bottommost node of the stack).
2. *Loop*: If *node* is an HTML element[p45] with the same tag name as the token, then:
    1. Generate implied end tags[p1263], except for HTML elements[p45] with the same tag name as the token.
    2. If *node* is not the current node[p1225], then this is a parse error[p1212].
    3. Pop all the nodes from the current node[p1225] up to *node*, including *node*, then stop these steps.
3. Otherwise, if *node* is in the special[p1226] category, then this is a parse error[p1212]; ignore the token, and return.
4. Set *node* to the previous entry in the stack of open elements[p1225].
5. Return to the step labeled *loop*.

When the steps above say the user agent is to **close a p element**, it means that the user agent must run the following steps:

1. Generate implied end tags[p1263], except for p[p223] elements.
2. If the current node[p1225] is not a p[p223] element, then this is a parse error[p1212].
3. Pop elements from the stack of open elements[p1225] until a p[p223] element has been popped from the stack.

The **adoption agency algorithm**, which takes as its only argument a token *token* for which the algorithm is being run, consists of the following steps:

1. Let *subject* be *token*'s tag name.
2. If the current node[p1225] is an HTML element[p45] whose tag name is *subject*, and the current node[p1225] is not in the list of active

formatting elements[p1227], then pop the current node[p1225] off the stack of open elements[p1225] and return.

3. Let *outer loop counter* be 0.

4. While true:

    1. If *outer loop counter* is greater than or equal to 8, then return.

    2. Increment *outer loop counter* by 1.

    3. Let *formatting element* be the last element in the list of active formatting elements[p1227] that:

        - is between the end of the list and the last marker[p1227] in the list, if any, or the start of the list otherwise, and

        - has the tag name *subject*.

        If there is no such element, then return and instead act as described in the "any other end tag" entry above.

    4. If *formatting element* is not in the stack of open elements[p1225], then this is a parse error[p1212]; remove the element from the list, and return.

    5. If *formatting element* is in the stack of open elements[p1225], but the element is not in scope[p1226], then this is a parse error[p1212]; return.

    6. If *formatting element* is not the current node[p1225], this is a parse error[p1212]. (But do not return.)

    7. Let *furthest block* be the topmost node in the stack of open elements[p1225] that is lower in the stack than *formatting element*, and is an element in the special[p1226] category. There might not be one.

    8. If there is no *furthest block*, then the UA must first pop all the nodes from the bottom of the stack of open elements[p1225], from the current node[p1225] up to and including *formatting element*, then remove *formatting element* from the list of active formatting elements[p1227], and finally return.

    9. Let *common ancestor* be the element immediately above *formatting element* in the stack of open elements[p1225].

    10. Let a bookmark note the position of *formatting element* in the list of active formatting elements[p1227] relative to the elements on either side of it in the list.

    11. Let *node* and *last node* be *furthest block*.

    12. Let *inner loop counter* be 0.

    13. While true:

        1. Increment *inner loop counter* by 1.

        2. Let *node* be the element immediately above *node* in the stack of open elements[p1225], or if *node* is no longer in the stack of open elements[p1225] (e.g. because it got removed by this algorithm), the element that was immediately above *node* in the stack of open elements[p1225] before *node* was removed.

        3. If *node* is *formatting element*, then break.

        4. If *inner loop counter* is greater than 3 and *node* is in the list of active formatting elements[p1227], then remove *node* from the list of active formatting elements[p1227].

        5. If *node* is not in the list of active formatting elements[p1227], then remove *node* from the stack of open elements[p1225] and continue.

        6. Create an element for the token[p1258] for which the element *node* was created, in the HTML namespace, with *common ancestor* as the intended parent; replace the entry for *node* in the list of active formatting elements[p1227] with an entry for the new element, replace the entry for *node* in the stack of open elements[p1225] with an entry for the new element, and let *node* be the new element.

        7. If *last node* is *furthest block*, then move the aforementioned bookmark to be immediately after the new *node* in the list of active formatting elements[p1227].

        8. Append *last node* to *node*.

        9. Set *last node* to *node*.

14. Insert whatever *last node* ended up being in the previous step at the appropriate place for inserting a node[p1258], but using *common ancestor* as the *override target*.

15. Create an element for the token[p1258] for which *formatting element* was created, in the HTML namespace, with *furthest block* as the intended parent.

16. Take all of the child nodes of *furthest block* and append them to the element created in the last step.

17. Append that new element to *furthest block*.

18. Remove *formatting element* from the list of active formatting elements[p1227], and insert the new element into the list of active formatting elements[p1227] at the position of the aforementioned bookmark.

19. Remove *formatting element* from the stack of open elements[p1225], and insert the new element into the stack of open elements[p1225] immediately below the position of *furthest block* in that stack.

Note

This algorithm's name, the "adoption agency algorithm", comes from the way it causes elements to change parents, and is in contrast with other possible algorithms for dealing with misnested content.

13.2.6.4.8 The "text" insertion mode §[p1280]

When the user agent is to apply the rules for the "text[p1280]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token**

Insert the token's character[p1262].

Note

This can never be a U+0000 NULL character; the tokenizer converts those to U+FFFD REPLACEMENT CHARACTER characters.

↪ **An end-of-file token**

Parse error[p1212].

If the current node[p1225] is a `script`[p638] element, then set its already started[p645] to true.

Pop the current node[p1225] off the stack of open elements[p1225].

Switch the insertion mode[p1224] to the original insertion mode[p1224] and reprocess the token.

↪ **An end tag whose tag name is "script"**

If the active speculative HTML parser[p1298] is null and the JavaScript execution context stack is empty, then perform a microtask checkpoint[p1077].

Let *script* be the current node[p1225] (which will be a `script`[p638] element).

Pop the current node[p1225] off the stack of open elements[p1225].

Switch the insertion mode[p1224] to the original insertion mode[p1224].

Let the *old insertion point* have the same value as the current insertion point[p1224]. Let the insertion point[p1224] be just before the next input character[p1224].

Increment the parser's script nesting level[p1212] by one.

If the active speculative HTML parser[p1298] is null, then prepare the script element[p646] *script*. This might cause some script to execute, which might cause new characters to be inserted into the tokenizer[p1099], and might cause the tokenizer to output more tokens, resulting in a reentrant invocation of the parser[p1211].

Decrement the parser's script nesting level[p1212] by one. If the parser's script nesting level[p1212] is zero, then set the parser pause flag[p1212] to false.

Let the insertion point[p1224] have the value of the *old insertion point*. (In other words, restore the insertion point[p1224] to its previous value. This value might be the "undefined" value.)

At this stage, if the pending parsing-blocking script[p650] is not null, then:

↪ **If the script nesting level[p1212] is not zero:**

Set the parser pause flag[p1212] to true, and abort the processing of any nested invocations of the tokenizer, yielding control back to the caller. (Tokenization will resume when the caller returns to the "outer" tree construction stage.)

> **Note**
>
> *The tree construction stage of this particular parser is being called reentrantly[p1211], say from a call to* `document.write()`[p1099].

↪ **Otherwise:**

While the pending parsing-blocking script[p650] is not null:

1. Let *the script* be the pending parsing-blocking script[p650].
2. Set the pending parsing-blocking script[p650] to null.
3. Start the speculative HTML parser[p1298] for this instance of the HTML parser.
4. Block the tokenizer[p1229] for this instance of the HTML parser[p1210], such that the event loop[p1071] will not run tasks[p1071] that invoke the tokenizer[p1229].
5. If the parser's `Document`[p127] has a style sheet that is blocking scripts[p199] or *the script*'s ready to be parser-executed[p645] is false: spin the event loop[p1078] until the parser's `Document`[p127] has no style sheet that is blocking scripts[p199] and *the script*'s ready to be parser-executed[p645] becomes true.
6. If this parser has been aborted[p1297] in the meantime, return.

   > **Note**
   >
   > *This could happen if, e.g., while the spin the event loop[p1078] algorithm is running, the* `Document`[p127] *gets destroyed[p1023], or the* `document.open()`[p1098] *method gets invoked on the* `Document`[p127].

7. Stop the speculative HTML parser[p1299] for this instance of the HTML parser.
8. Unblock the tokenizer[p1229] for this instance of the HTML parser[p1210], such that tasks[p1071] that invoke the tokenizer[p1229] can again be run.
9. Let the insertion point[p1224] be just before the next input character[p1224].
10. Increment the parser's script nesting level[p1212] by one (it should be zero before this step, so this sets it to one).
11. Execute the script element[p650] *the script*.
12. Decrement the parser's script nesting level[p1212] by one. If the parser's script nesting level[p1212] is zero (which it always should be at this point), then set the parser pause flag[p1212] to false.
13. Let the insertion point[p1224] be undefined again.

↪ **Any other end tag**

Pop the current node[p1225] off the stack of open elements[p1225].

Switch the insertion mode[p1224] to the original insertion mode[p1224].

13.2.6.4.9 The "in table" insertion mode §[p1281]

When the user agent is to apply the rules for the "in table[p1281]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token, if the current node[p1225] is `table`[p469], `tbody`[p480], `template`[p656], `tfoot`[p482], `thead`[p481], or `tr`[p483] element**

Let the ***pending table character tokens*** be an empty list of tokens.

Let the original insertion mode[p1224] be the current insertion mode[p1224].

Switch the insertion mode[p1224] to "in table text[p1283]" and reprocess the token.

↪ **A comment token**

Insert a comment[p1262].

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is "caption"**

Clear the stack back to a table context[p1283]. (See below.)

Insert a marker[p1227] at the end of the list of active formatting elements[p1227].

Insert an HTML element[p1260] for the token, then switch the insertion mode[p1224] to "in caption[p1284]".

↪ **A start tag whose tag name is "colgroup"**

Clear the stack back to a table context[p1283]. (See below.)

Insert an HTML element[p1260] for the token, then switch the insertion mode[p1224] to "in column group[p1284]".

↪ **A start tag whose tag name is "col"**

Clear the stack back to a table context[p1283]. (See below.)

Insert an HTML element[p1260] for a "colgroup" start tag token with no attributes, then switch the insertion mode[p1224] to "in column group[p1284]".

Reprocess the current token.

↪ **A start tag whose tag name is one of: "tbody", "tfoot", "thead"**

Clear the stack back to a table context[p1283]. (See below.)

Insert an HTML element[p1260] for the token, then switch the insertion mode[p1224] to "in table body[p1285]".

↪ **A start tag whose tag name is one of: "td", "th", "tr"**

Clear the stack back to a table context[p1283]. (See below.)

Insert an HTML element[p1260] for a "tbody" start tag token with no attributes, then switch the insertion mode[p1224] to "in table body[p1285]".

Reprocess the current token.

↪ **A start tag whose tag name is "table"**

Parse error[p1212].

If the stack of open elements[p1225] does not have a `table` element in table scope[p1227], ignore the token.

Otherwise:

Pop elements from this stack until a `table`[p469] element has been popped from the stack.

Reset the insertion mode appropriately[p1224].

Reprocess the token.

↪ **An end tag whose tag name is "table"**

If the stack of open elements[p1225] does not have a `table` element in table scope[p1227], this is a parse error[p1212]; ignore the token.

Otherwise:

Pop elements from this stack until a `table`[p469] element has been popped from the stack.

Reset the insertion mode appropriately[p1224].

↪ **An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "tbody", "td", "tfoot", "th",**

"thead", "tr"

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is one of: "style", "script", "template"**

↪ **An end tag whose tag name is "template"**

Process the token using the rules for[p1224] the "in head[p1266]" insertion mode[p1224].

↪ **A start tag whose tag name is "input"**

If the token does not have an attribute with the name "type", or if it does, but that attribute's value is not an ASCII case-insensitive match for the string "`hidden`", then: act as described in the "anything else" entry below.

Otherwise:

Parse error[p1212].

Insert an HTML element[p1260] for the token.

Pop that `input`[p512] element off the stack of open elements[p1225].

Acknowledge the token's *self-closing flag*[p1229], if it is set.

↪ **A start tag whose tag name is "form"**

Parse error[p1212].

If there is a `template`[p656] element on the stack of open elements[p1225], or if the `form` element pointer[p1228] is not null, ignore the token.

Otherwise:

Insert an HTML element[p1260] for the token, and set the `form` element pointer[p1228] to point to the element created.

Pop that `form`[p505] element off the stack of open elements[p1225].

↪ **An end-of-file token**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **Anything else**

Parse error[p1212]. Enable foster parenting[p1258], process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224], and then disable foster parenting[p1258].

When the steps above require the UA to **clear the stack back to a table context**, it means that the UA must, while the current node[p1225] is not a `table`[p469], `template`[p656], or `html`[p167] element, pop elements from the stack of open elements[p1225].

Note

This is the same list of elements as used in the has an element in table scope[p1227] steps.

Note

The current node[p1225] being an `html`[p167] element after this process is a fragment case[p1311].

13.2.6.4.10 The "in table text" insertion mode §[p1283]

When the user agent is to apply the rules for the "in table text[p1283]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token that is U+0000 NULL**

Parse error[p1212]. Ignore the token.

↪ **Any other character token**

Append the character token to the *pending table character tokens*[p1281] list.

↪ **Anything else**

If any of the tokens in the *pending table character tokens*[p1281] list are character tokens that are not ASCII whitespace, then this is a parse error[p1212]: reprocess the character tokens in the *pending table character tokens*[p1281] list using the rules given in the "anything else" entry in the "in table[p1281]" insertion mode.

Otherwise, insert the characters[p1262] given by the *pending table character tokens*[p1281] list.

Switch the insertion mode[p1224] to the original insertion mode[p1224] and reprocess the token.

13.2.6.4.11 The "in caption" insertion mode §[p1284]

When the user agent is to apply the rules for the "in caption[p1284]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **An end tag whose tag name is "caption"**

If the stack of open elements[p1225] does not have a `caption` element in table scope[p1227], this is a parse error[p1212]; ignore the token. (fragment case[p1311])

Otherwise:

Generate implied end tags[p1263].

Now, if the current node[p1225] is not a `caption`[p477] element, then this is a parse error[p1212].

Pop elements from this stack until a `caption`[p477] element has been popped from the stack.

Clear the list of active formatting elements up to the last marker[p1228].

Switch the insertion mode[p1224] to "in table[p1281]".

↪ **A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "td", "tfoot", "th", "thead", "tr"**

↪ **An end tag whose tag name is "table"**

If the stack of open elements[p1225] does not have a `caption` element in table scope[p1227], this is a parse error[p1212]; ignore the token. (fragment case[p1311])

Otherwise:

Generate implied end tags[p1263].

Now, if the current node[p1225] is not a `caption`[p477] element, then this is a parse error[p1212].

Pop elements from this stack until a `caption`[p477] element has been popped from the stack.

Clear the list of active formatting elements up to the last marker[p1228].

Switch the insertion mode[p1224] to "in table[p1281]".

Reprocess the token.

↪ **An end tag whose tag name is one of: "body", "col", "colgroup", "html", "tbody", "td", "tfoot", "th", "thead", "tr"**

Parse error[p1212]. Ignore the token.

↪ **Anything else**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

13.2.6.4.12 The "in column group" insertion mode §[p1284]

When the user agent is to apply the rules for the "in column group[p1284]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED**

(FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE

Insert the character[p1262].

↪ **A comment token**

Insert a comment[p1262].

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **A start tag whose tag name is "col"**

Insert an HTML element[p1260] for the token. Immediately pop the current node[p1225] off the stack of open elements[p1225].

Acknowledge the token's *self-closing flag*[p1229], if it is set.

↪ **An end tag whose tag name is "colgroup"**

If the current node[p1225] is not a `colgroup`[p478] element, then this is a parse error[p1212]; ignore the token.

Otherwise, pop the current node[p1225] from the stack of open elements[p1225]. Switch the insertion mode[p1224] to "in table[p1281]".

↪ **An end tag whose tag name is "col"**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is "template"**

↪ **An end tag whose tag name is "template"**

Process the token using the rules for[p1224] the "in head[p1266]" insertion mode[p1224].

↪ **An end-of-file token**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **Anything else**

If the current node[p1225] is not a `colgroup`[p478] element, then this is a parse error[p1212]; ignore the token.

Otherwise, pop the current node[p1225] from the stack of open elements[p1225].

Switch the insertion mode[p1224] to "in table[p1281]".

Reprocess the token.

13.2.6.4.13 The "in table body" insertion mode §[p1285]

When the user agent is to apply the rules for the "in table body[p1285]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A start tag whose tag name is "tr"**

Clear the stack back to a table body context[p1286]. (See below.)

Insert an HTML element[p1260] for the token, then switch the insertion mode[p1224] to "in row[p1286]".

↪ **A start tag whose tag name is one of: "th", "td"**

Parse error[p1212].

Clear the stack back to a table body context[p1286]. (See below.)

Insert an HTML element[p1260] for a "tr" start tag token with no attributes, then switch the insertion mode[p1224] to "in row[p1286]".

Reprocess the current token.

↪ **An end tag whose tag name is one of: "tbody", "tfoot", "thead"**

If the stack of open elements[p1225] does not have an element in table scope[p1227] that is an HTML element[p45] with the same tag name as the token, this is a parse error[p1212]; ignore the token.

Otherwise:

Clear the stack back to a table body context[p1286]. (See below.)

Pop the current node[p1225] from the stack of open elements[p1225]. Switch the insertion mode[p1224] to "in table[p1281]".

↪ **A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead"**

↪ **An end tag whose tag name is "table"**

If the stack of open elements[p1225] does not have a `tbody`, `thead`, or `tfoot` element in table scope[p1227], this is a parse error[p1212]; ignore the token.

Otherwise:

Clear the stack back to a table body context[p1286]. (See below.)

Pop the current node[p1225] from the stack of open elements[p1225]. Switch the insertion mode[p1224] to "in table[p1281]".

Reprocess the token.

↪ **An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th", "tr"**

Parse error[p1212]. Ignore the token.

↪ **Anything else**

Process the token using the rules for[p1224] the "in table[p1281]" insertion mode[p1224].

When the steps above require the UA to **clear the stack back to a table body context**, it means that the UA must, while the current node[p1225] is not a `tbody`[p480], `tfoot`[p482], `thead`[p481], `template`[p656], or `html`[p167] element, pop elements from the stack of open elements[p1225].

Note

The current node[p1225] being an `html`[p167] element after this process is a fragment case[p1311].

13.2.6.4.14 The "in row" insertion mode §[p1286]

When the user agent is to apply the rules for the "in row[p1286]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A start tag whose tag name is one of: "th", "td"**

Clear the stack back to a table row context[p1287]. (See below.)

Insert an HTML element[p1260] for the token, then switch the insertion mode[p1224] to "in cell[p1287]".

Insert a marker[p1227] at the end of the list of active formatting elements[p1227].

↪ **An end tag whose tag name is "tr"**

If the stack of open elements[p1225] does not have a `tr` element in table scope[p1227], this is a parse error[p1212]; ignore the token.

Otherwise:

Clear the stack back to a table row context[p1287]. (See below.)

Pop the current node[p1225] (which will be a `tr`[p483] element) from the stack of open elements[p1225]. Switch the insertion mode[p1224] to "in table body[p1285]".

↪ **A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "tfoot", "thead", "tr"**

↪ **An end tag whose tag name is "table"**

If the stack of open elements[p1225] does not have a `tr` element in table scope[p1227], this is a parse error[p1212]; ignore the token.

Otherwise:

Clear the stack back to a table row context[p1287]. (See below.)

Pop the current node[p1225] (which will be a `tr`[p483] element) from the stack of open elements[p1225]. Switch the insertion mode[p1224] to "in table body[p1285]".

Reprocess the token.

↪ **An end tag whose tag name is one of: "tbody", "tfoot", "thead"**

If the stack of open elements[p1225] does not have an element in table scope[p1227] that is an HTML element[p45] with the same tag name as the token, this is a parse error[p1212]; ignore the token.

If the stack of open elements[p1225] does not have a `tr` element in table scope[p1227], ignore the token.

Otherwise:

Clear the stack back to a table row context[p1287]. (See below.)

Pop the current node[p1225] (which will be a `tr`[p483] element) from the stack of open elements[p1225]. Switch the insertion mode[p1224] to "in table body[p1285]".

Reprocess the token.

↪ **An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html", "td", "th"**

Parse error[p1212]. Ignore the token.

↪ **Anything else**

Process the token using the rules for[p1224] the "in table[p1281]" insertion mode[p1224].

When the steps above require the UA to **clear the stack back to a table row context**, it means that the UA must, while the current node[p1225] is not a `tr`[p483], `template`[p656], or `html`[p167] element, pop elements from the stack of open elements[p1225].

Note

The current node[p1225] being an `html`[p167] element after this process is a fragment case[p1311].

13.2.6.4.15 The "in cell" insertion mode §[p1287]

When the user agent is to apply the rules for the "in cell[p1287]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **An end tag whose tag name is one of: "td", "th"**

If the stack of open elements[p1225] does not have an element in table scope[p1227] that is an HTML element[p45] with the same tag name as that of the token, then this is a parse error[p1212]; ignore the token.

Otherwise:

Generate implied end tags[p1263].

Now, if the current node[p1225] is not an HTML element[p45] with the same tag name as the token, then this is a parse error[p1212].

Pop elements from the stack of open elements[p1225] stack until an HTML element[p45] with the same tag name as the token has been popped from the stack.

Clear the list of active formatting elements up to the last marker[p1228].

Switch the insertion mode[p1224] to "in row[p1286]".

↪ **A start tag whose tag name is one of: "caption", "col", "colgroup", "tbody", "td", "tfoot", "th", "thead", "tr"**

If the stack of open elements[p1225] does *not* have a `td` or `th` element in table scope[p1227], then this is a parse error[p1212]; ignore the token. (fragment case[p1311])

Otherwise, close the cell[p1288] (see below) and reprocess the token.

↪ **An end tag whose tag name is one of: "body", "caption", "col", "colgroup", "html"**

Parse error[p1212]. Ignore the token.

↪ **An end tag whose tag name is one of: "table", "tbody", "tfoot", "thead", "tr"**

If the stack of open elements[p1225] does not have an element in table scope[p1227] that is an HTML element[p45] with the same tag name as that of the token, then this is a parse error[p1212]; ignore the token.

Otherwise, close the cell[p1288] (see below) and reprocess the token.

↪ **Anything else**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

Where the steps above say to **close the cell**, they mean to run the following algorithm:

1. Generate implied end tags[p1263].
2. If the current node[p1225] is not now a `td`[p484] element or a `th`[p486] element, then this is a parse error[p1212].
3. Pop elements from the stack of open elements[p1225] stack until a `td`[p484] element or a `th`[p486] element has been popped from the stack.
4. Clear the list of active formatting elements up to the last marker[p1228].
5. Switch the insertion mode[p1224] to "in row[p1286]".

Note

The stack of open elements[p1225] cannot have both a `td`[p484] and a `th`[p486] element in table scope[p1227] at the same time, nor can it have neither when the close the cell[p1288] algorithm is invoked.

13.2.6.4.16 The "in select" insertion mode §[p1288]

When the user agent is to apply the rules for the "in select[p1288]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token that is U+0000 NULL**

Parse error[p1212]. Ignore the token.

↪ **Any other character token**

Insert the token's character[p1262].

↪ **A comment token**

Insert a comment[p1262].

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **A start tag whose tag name is "option"**

If the current node[p1225] is an `option`[p567] element, pop that node from the stack of open elements[p1225].

Insert an HTML element[p1260] for the token.

↪ **A start tag whose tag name is "optgroup"**

If the current node[p1225] is an `option`[p567] element, pop that node from the stack of open elements[p1225].

If the current node[p1225] is an `optgroup`[p566] element, pop that node from the stack of open elements[p1225].

Insert an HTML element[p1260] for the token.

↪ **A start tag whose tag name is "hr"**

If the current node[p1225] is an `option`[p567] element, pop that node from the stack of open elements[p1225].

If the current node[p1225] is an `optgroup`[p566] element, pop that node from the stack of open elements[p1225].

Insert an HTML element[p1260] for the token. Immediately pop the current node[p1225] off the stack of open elements[p1225].

Acknowledge the token's *self-closing flag*[p1229], if it is set.

↪ **An end tag whose tag name is "optgroup"**

First, if the current node[p1225] is an `option`[p567] element, and the node immediately before it in the stack of open elements[p1225] is an `optgroup`[p566] element, then pop the current node[p1225] from the stack of open elements[p1225].

If the current node[p1225] is an `optgroup`[p566] element, then pop that node from the stack of open elements[p1225]. Otherwise, this is a parse error[p1212]; ignore the token.

↪ **An end tag whose tag name is "option"**

If the current node[p1225] is an `option`[p567] element, then pop that node from the stack of open elements[p1225]. Otherwise, this is a parse error[p1212]; ignore the token.

↪ **An end tag whose tag name is "select"**

If the stack of open elements[p1225] does not have a `select` element in select scope[p1227], this is a parse error[p1212]; ignore the token. (fragment case[p1311])

Otherwise:

Pop elements from the stack of open elements[p1225] until a `select`[p559] element has been popped from the stack.

Reset the insertion mode appropriately[p1224].

↪ **A start tag whose tag name is "select"**

Parse error[p1212].

If the stack of open elements[p1225] does not have a `select` element in select scope[p1227], ignore the token. (fragment case[p1311])

Otherwise:

Pop elements from the stack of open elements[p1225] until a `select`[p559] element has been popped from the stack.

Reset the insertion mode appropriately[p1224].

Note

It just gets treated like an end tag.

↪ **A start tag whose tag name is one of: "input", "keygen", "textarea"**

Parse error[p1212].

If the stack of open elements[p1225] does not have a `select` element in select scope[p1227], ignore the token. (fragment case[p1311])

Otherwise:

Pop elements from the stack of open elements[p1225] until a `select`[p559] element has been popped from the stack.

Reset the insertion mode appropriately[p1224].

Reprocess the token.

↪ **A start tag whose tag name is one of: "script", "template"**

↪ **An end tag whose tag name is "template"**

Process the token using the rules for[p1224] the "in head[p1266]" insertion mode[p1224].

↪ **An end-of-file token**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **Anything else**

Parse error[p1212]. Ignore the token.

13.2.6.4.17 The "in select in table" insertion mode §[p1290]

When the user agent is to apply the rules for the "in select in table[p1290]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A start tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"**

Parse error[p1212].

Pop elements from the stack of open elements[p1225] until a `select`[p559] element has been popped from the stack.

Reset the insertion mode appropriately[p1224].

Reprocess the token.

↪ **An end tag whose tag name is one of: "caption", "table", "tbody", "tfoot", "thead", "tr", "td", "th"**

Parse error[p1212].

If the stack of open elements[p1225] does not have an element in table scope[p1227] that is an HTML element[p45] with the same tag name as that of the token, then ignore the token.

Otherwise:

Pop elements from the stack of open elements[p1225] until a `select`[p559] element has been popped from the stack.

Reset the insertion mode appropriately[p1224].

Reprocess the token.

↪ **Anything else**

Process the token using the rules for[p1224] the "in select[p1288]" insertion mode[p1224].

13.2.6.4.18 The "in template" insertion mode §[p1290]

When the user agent is to apply the rules for the "in template[p1290]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token**

↪ **A comment token**

↪ **A DOCTYPE token**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **A start tag whose tag name is one of: "base", "basefont", "bgsound", "link", "meta", "noframes", "script", "style", "template", "title"**

↪ **An end tag whose tag name is "template"**

Process the token using the rules for[p1224] the "in head[p1266]" insertion mode[p1224].

↪ **A start tag whose tag name is one of: "caption", "colgroup", "tbody", "tfoot", "thead"**

Pop the current template insertion mode[p1224] off the stack of template insertion modes[p1224].

Push "in table[p1281]" onto the stack of template insertion modes[p1224] so that it is the new current template insertion mode[p1224].

Switch the insertion mode[p1224] to "in table[p1281]", and reprocess the token.

↪ **A start tag whose tag name is "col"**

Pop the current template insertion mode[p1224] off the stack of template insertion modes[p1224].

Push "in column group[p1284]" onto the stack of template insertion modes[p1224] so that it is the new current template insertion mode[p1224].

Switch the insertion mode[p1224] to "in column group[p1284]", and reprocess the token.

↪ **A start tag whose tag name is "tr"**

Pop the current template insertion mode[p1224] off the stack of template insertion modes[p1224].

Push "in table body[p1285]" onto the stack of template insertion modes[p1224] so that it is the new current template insertion mode[p1224].

Switch the insertion mode[p1224] to "in table body[p1285]", and reprocess the token.

↪ **A start tag whose tag name is one of: "td", "th"**

Pop the current template insertion mode[p1224] off the stack of template insertion modes[p1224].

Push "in row[p1286]" onto the stack of template insertion modes[p1224] so that it is the new current template insertion mode[p1224].

Switch the insertion mode[p1224] to "in row[p1286]", and reprocess the token.

↪ **Any other start tag**

Pop the current template insertion mode[p1224] off the stack of template insertion modes[p1224].

Push "in body[p1270]" onto the stack of template insertion modes[p1224] so that it is the new current template insertion mode[p1224].

Switch the insertion mode[p1224] to "in body[p1270]", and reprocess the token.

↪ **Any other end tag**

Parse error[p1212]. Ignore the token.

↪ **An end-of-file token**

If there is no `template`[p656] element on the stack of open elements[p1225], then stop parsing[p1296]. (fragment case[p1311])

Otherwise, this is a parse error[p1212].

Pop elements from the stack of open elements[p1225] until a `template`[p656] element has been popped from the stack.

Clear the list of active formatting elements up to the last marker[p1228].

Pop the current template insertion mode[p1224] off the stack of template insertion modes[p1224].

Reset the insertion mode appropriately[p1224].

Reprocess the token.

13.2.6.4.19 The "after body" insertion mode §[p1291]

When the user agent is to apply the rules for the "after body[p1291]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **A comment token**

Insert a comment[p1262] as the last child of the first element in the stack of open elements[p1225] (the `html`[p167] element).

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **An end tag whose tag name is "html"**

If the parser was created as part of the HTML fragment parsing algorithm[p1310], this is a parse error[p1212]; ignore the token. (fragment case[p1311])

Otherwise, switch the insertion mode[p1224] to "after after body[p1293]".

↪ **An end-of-file token**

Stop parsing[p1296].

↪ **Anything else**

Parse error[p1212]. Switch the insertion mode[p1224] to "in body[p1270]" and reprocess the token.

13.2.6.4.20 The "in frameset" insertion mode §[p1292]

When the user agent is to apply the rules for the "in frameset[p1292]" insertion mode[p1224], the user agent must handle the token as follows:

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Insert the character[p1262].

↪ **A comment token**

Insert a comment[p1262].

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is "html"**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **A start tag whose tag name is "frameset"**

Insert an HTML element[p1260] for the token.

↪ **An end tag whose tag name is "frameset"**

If the current node[p1225] is the root `html`[p167] element, then this is a parse error[p1212]; ignore the token. (fragment case[p1311])

Otherwise, pop the current node[p1225] from the stack of open elements[p1225].

If the parser was not created as part of the HTML fragment parsing algorithm[p1310] (fragment case[p1311]), and the current node[p1225] is no longer a `frameset`[p1369] element, then switch the insertion mode[p1224] to "after frameset[p1293]".

↪ **A start tag whose tag name is "frame"**

Insert an HTML element[p1260] for the token. Immediately pop the current node[p1225] off the stack of open elements[p1225].

Acknowledge the token's *self-closing flag*[p1229], if it is set.

↪ **A start tag whose tag name is "noframes"**

Process the token using the rules for[p1224] the "in head[p1266]" insertion mode[p1224].

↪ **An end-of-file token**

If the current node[p1225] is not the root `html`[p167] element, then this is a parse error[p1212].

> **Note**
>
> *The current node[p1225] can only be the root `html`[p167] element in the fragment case[p1311].*

Stop parsing[p1296].

↪ **Anything else**

Parse error[p1212]. Ignore the token.

13.2.6.4.21 The "after frameset" insertion mode §p1293

When the user agent is to apply the rules for the "after frameset p1293" insertion mode p1224, the user agent must handle the token as follows:

- **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

  Insert the character p1262.

- **A comment token**

  Insert a comment p1262.

- **A DOCTYPE token**

  Parse error p1212. Ignore the token.

- **A start tag whose tag name is "html"**

  Process the token using the rules for p1224 the "in body p1270" insertion mode p1224.

- **An end tag whose tag name is "html"**

  Switch the insertion mode p1224 to "after after frameset p1293".

- **A start tag whose tag name is "noframes"**

  Process the token using the rules for p1224 the "in head p1266" insertion mode p1224.

- **An end-of-file token**

  Stop parsing p1296.

- **Anything else**

  Parse error p1212. Ignore the token.

13.2.6.4.22 The "after after body" insertion mode §p1293

When the user agent is to apply the rules for the "after after body p1293" insertion mode p1224, the user agent must handle the token as follows:

- **A comment token**

  Insert a comment p1262 as the last child of the `Document` p127 object.

- **A DOCTYPE token**
- **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**
- **A start tag whose tag name is "html"**

  Process the token using the rules for p1224 the "in body p1270" insertion mode p1224.

- **An end-of-file token**

  Stop parsing p1296.

- **Anything else**

  Parse error p1212. Switch the insertion mode p1224 to "in body p1270" and reprocess the token.

13.2.6.4.23 The "after after frameset" insertion mode §p1293

When the user agent is to apply the rules for the "after after frameset p1293" insertion mode p1224, the user agent must handle the token as follows:

- **A comment token**

  Insert a comment p1262 as the last child of the `Document` p127 object.

↪ **A DOCTYPE token**

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

↪ **A start tag whose tag name is "html"**

Process the token using the rules for[p1224] the "in body[p1270]" insertion mode[p1224].

↪ **An end-of-file token**

Stop parsing[p1296].

↪ **A start tag whose tag name is "noframes"**

Process the token using the rules for[p1224] the "in head[p1266]" insertion mode[p1224].

↪ **Anything else**

Parse error[p1212]. Ignore the token.

13.2.6.5 The rules for parsing tokens in foreign content §[p1294]

When the user agent is to apply the rules for parsing tokens in foreign content, the user agent must handle the token as follows:

↪ **A character token that is U+0000 NULL**

Parse error[p1212]. Insert a U+FFFD REPLACEMENT CHARACTER character[p1262].

↪ **A character token that is one of U+0009 CHARACTER TABULATION, U+000A LINE FEED (LF), U+000C FORM FEED (FF), U+000D CARRIAGE RETURN (CR), or U+0020 SPACE**

Insert the token's character[p1262].

↪ **Any other character token**

Insert the token's character[p1262].

Set the frameset-ok flag[p1228] to "not ok".

↪ **A comment token**

Insert a comment[p1262].

↪ **A DOCTYPE token**

Parse error[p1212]. Ignore the token.

↪ **A start tag whose tag name is one of: "b", "big", "blockquote", "body", "br", "center", "code", "dd", "div", "dl", "dt", "em", "embed", "h1", "h2", "h3", "h4", "h5", "h6", "head", "hr", "i", "img", "li", "listing", "menu", "meta", "nobr", "ol", "p", "pre", "ruby", "s", "small", "span", "strong", "strike", "sub", "sup", "table", "tt", "u", "ul", "var"**

↪ **A start tag whose tag name is "font", if the token has any attributes named "color", "face", or "size"**

↪ **An end tag whose tag name is "br", "p"**

Parse error[p1212].

While the current node[p1225] is not a MathML text integration point[p1257], an HTML integration point[p1257], or an element in the HTML namespace, pop elements from the stack of open elements[p1225].

Reprocess the token according to the rules given in the section corresponding to the current insertion mode[p1224] in HTML content.

↪ **Any other start tag**

If the adjusted current node[p1226] is an element in the MathML namespace, adjust MathML attributes[p1260] for the token. (This fixes the case of MathML attributes that are not all lowercase.)

If the adjusted current node[p1226] is an element in the SVG namespace, and the token's tag name is one of the ones in the first column of the following table, change the tag name to the name given in the corresponding cell in the second column. (This fixes the case of SVG elements that are not all lowercase.)

Tag name	Element name
altglyph	altGlyph

Tag name	Element name
altglyphdef	altGlyphDef
altglyphitem	altGlyphItem
animatecolor	animateColor
animatemotion	animateMotion
animatetransform	animateTransform
clippath	clipPath
feblend	feBlend
fecolormatrix	feColorMatrix
fecomponenttransfer	feComponentTransfer
fecomposite	feComposite
feconvolvematrix	feConvolveMatrix
fediffuselighting	feDiffuseLighting
fedisplacementmap	feDisplacementMap
fedistantlight	feDistantLight
fedropshadow	feDropShadow
feflood	feFlood
fefunca	feFuncA
fefuncb	feFuncB
fefuncg	feFuncG
fefuncr	feFuncR
fegaussianblur	feGaussianBlur
feimage	feImage
femerge	feMerge
femergenode	feMergeNode
femorphology	feMorphology
feoffset	feOffset
fepointlight	fePointLight
fespecularlighting	feSpecularLighting
fespotlight	feSpotLight
fetile	feTile
feturbulence	feTurbulence
foreignobject	foreignObject
glyphref	glyphRef
lineargradient	linearGradient
radialgradient	radialGradient
textpath	textPath

If the adjusted current node[p1226] is an element in the SVG namespace, adjust SVG attributes[p1260] for the token. (This fixes the case of SVG attributes that are not all lowercase.)

Adjust foreign attributes[p1261] for the token. (This fixes the use of namespaced attributes, in particular XLink in SVG.)

Insert a foreign element[p1260] for the token, in the same namespace as the adjusted current node[p1226].

If the token has its *self-closing flag*[p1229] set, then run the appropriate steps from the following list:

↪ **If the token's tag name is "script", and the new current node[p1225] is in the SVG namespace**
Acknowledge the token's *self-closing flag*[p1229], and then act as described in the steps for a "script" end tag below.

↪ **Otherwise**
Pop the current node[p1225] off the stack of open elements[p1225] and acknowledge the token's *self-closing flag*[p1229].

↪ **An end tag whose tag name is "script", if the current node[p1225] is an SVG `script` element**
Pop the current node[p1225] off the stack of open elements[p1225].

Let the *old insertion point* have the same value as the current insertion point[p1224]. Let the insertion point[p1224] be just before the next input character[p1224].

Increment the parser's script nesting level[p1212] by one. Set the parser pause flag[p1212] to true.

If the active speculative HTML parser[p1298] is null and the user agent supports SVG, then Process the SVG `script` element according to the SVG rules. [SVG][p1417]

Note

Even if this causes new characters to be inserted into the tokenizer[p1099], the parser will not be executed reentrantly, since the parser pause flag[p1212] is true.

Decrement the parser's script nesting level[p1212] by one. If the parser's script nesting level[p1212] is zero, then set the parser pause flag[p1212] to false.

Let the insertion point[p1224] have the value of the *old insertion point*. (In other words, restore the insertion point[p1224] to its previous value. This value might be the "undefined" value.)

↪ **Any other end tag**

Run these steps:

1. Initialize *node* to be the current node[p1225] (the bottommost node of the stack).
2. If *node*'s tag name, converted to ASCII lowercase, is not the same as the tag name of the token, then this is a parse error[p1212].
3. *Loop*: If *node* is the topmost element in the stack of open elements[p1225], then return. (fragment case[p1311])
4. If *node*'s tag name, converted to ASCII lowercase, is the same as the tag name of the token, pop elements from the stack of open elements[p1225] until *node* has been popped from the stack, and then return.
5. Set *node* to the previous entry in the stack of open elements[p1225].
6. If *node* is not an element in the HTML namespace, return to the step labeled *loop*.
7. Otherwise, process the token according to the rules given in the section corresponding to the current insertion mode[p1224] in HTML content.

13.2.7 The end §[p1296]

Once the user agent **stops parsing** the document, the user agent must run the following steps:

1. If the active speculative HTML parser[p1298] is not null, then stop the speculative HTML parser[p1299] and return.
2. Set the insertion point[p1224] to undefined.
3. Update the current document readiness[p130] to "`interactive`".
4. Pop *all* the nodes off the stack of open elements[p1225].
5. While the list of scripts that will execute when the document has finished parsing[p650] is not empty:
    1. Spin the event loop[p1078] until the first `script`[p638] in the list of scripts that will execute when the document has finished parsing[p650] has its ready to be parser-executed[p645] set to true *and* the parser's `Document`[p127] has no style sheet that is blocking scripts[p199].
    2. Execute the script element[p650] given by the first `script`[p638] in the list of scripts that will execute when the document has finished parsing[p650].
    3. Remove the first `script`[p638] element from the list of scripts that will execute when the document has finished parsing[p650] (i.e. shift out the first entry in the list).
6. Queue a global task[p1073] on the DOM manipulation task source[p1080] given the `Document`[p127]'s relevant global object[p1039] to run the following substeps:
    1. Set the `Document`[p127]'s load timing info[p131]'s DOM content loaded event start time[p131] to the current high resolution

time given the Document[p127]'s relevant global object[p1039].

2. Fire an event named DOMContentLoaded[p1406] at the Document[p127] object, with its bubbles attribute initialized to true.

3. Set the Document[p127]'s load timing info[p131]'s DOM content loaded event end time[p131] to the current high resolution time given the Document[p127]'s relevant global object[p1039].

4. Enable the client message queue of the ServiceWorkerContainer object whose associated service worker client is the Document[p127] object's relevant settings object[p1039].

5. Invoke WebDriver BiDi DOM content loaded with the Document[p127]'s browsing context[p961], and a new WebDriver BiDi navigation status whose id is the Document[p127] object's navigation id[p128], status is "pending", and url is the Document[p127] object's URL.

7. Spin the event loop[p1078] until the set of scripts that will execute as soon as possible[p650] and the list of scripts that will execute in order as soon as possible[p650] are empty.

8. Spin the event loop[p1078] until there is nothing that **delays the load event** in the Document[p127].

9. Queue a global task[p1073] on the DOM manipulation task source[p1080] given the Document[p127]'s relevant global object[p1039] to run the following steps:

    1. Update the current document readiness[p130] to "complete".

    2. If the Document[p127] object's browsing context[p961] is null, then abort these steps.

    3. Let *window* be the Document[p127]'s relevant global object[p1039].

    4. Set the Document[p127]'s load timing info[p131]'s load event start time[p131] to the current high resolution time given *window*.

    5. Fire an event named load[p1407] at *window*, with *legacy target override flag* set.

    6. Invoke WebDriver BiDi load complete with the Document[p127]'s browsing context[p961], and a new WebDriver BiDi navigation status whose id is the Document[p127] object's navigation id[p128], status is "complete", and url is the Document[p127] object's URL.

    7. Set the Document[p127] object's navigation id[p128] to null.

    8. Set the Document[p127]'s load timing info[p131]'s load event end time[p131] to the current high resolution time given *window*.

    9. Assert: Document[p127]'s page showing[p1021] is false.

    10. Set the Document[p127]'s page showing[p1021] flag to true.

    11. Fire a page transition event[p951] named pageshow[p1407] at *window* with false.

    12. Completely finish loading[p1021] the Document[p127].

    13. Queue the navigation timing entry for the Document[p127].

10. If the Document[p127]'s print when loaded[p1108] flag is set, then run the printing steps[p1108].

11. The Document[p127] is now **ready for post-load tasks**.

When the user agent is to **abort a parser**, it must run the following steps:

1. Throw away any pending content in the input stream[p1223], and discard any future content that would have been added to it.

2. Stop the speculative HTML parser[p1299] for this HTML parser.

3. Update the current document readiness[p130] to "interactive".

4. Pop *all* the nodes off the stack of open elements[p1225].

5. Update the current document readiness[p130] to "complete".

13.2.8 Speculative HTML parsing §[p1298]

User agents may implement an optimization, as described in this section, to speculatively fetch resources that are declared in the HTML markup while the HTML parser is waiting for a pending parsing-blocking script[p650] to be fetched and executed, or during normal parsing, at the time an element is created for a token[p1258]. While this optimization is not defined in precise detail, there are some rules to consider for interoperability.

Each HTML parser[p1210] can have an **active speculative HTML parser**. It is initially null.

The **speculative HTML parser** must act like the normal HTML parser (e.g., the tree builder rules apply), with some exceptions:

- The state of the normal HTML parser and the document itself must not be affected.

  Example

  For example, the next input character[p1224] or the stack of open elements[p1225] for the normal HTML parser is not affected by the speculative HTML parser[p1298].

- Bytes pushed into the HTML parser's input byte stream[p1216] must also be pushed into the speculative HTML parser's input byte stream[p1216]. Bytes read from the streams must be independent.

- The result of the speculative parsing is primarily a series of speculative fetches[p1298]. Which kinds of resources to speculatively fetch is implementation-defined, but user agents must not speculatively fetch resources that would not be fetched with the normal HTML parser, under the assumption that the script that is blocking the HTML parser does nothing.

  Note

  It is possible that the same markup is seen multiple times from the speculative HTML parser[p1298] and then the normal HTML parser. It is expected that duplicated fetches will be prevented by caching rules, which are not yet fully specified.

A **speculative fetch** for a speculative mock element[p1299] *element* must follow these rules:

Should some of these things be applied to the document "for real", even though they are found speculatively?

- If the speculative HTML parser[p1298] encounters one of the following elements, then act as if that element is processed for the purpose of its effect of subsequent speculative fetches.
  - A `base`[p170] element.
  - A `meta`[p184] element whose `http-equiv`[p190] attribute is in the Content security policy[p193] state.
  - A `meta`[p184] element whose `name`[p185] attribute is an ASCII case-insensitive match for "`referrer`[p187]".
  - A `meta`[p184] element whose `name`[p185] attribute is an ASCII case-insensitive match for "`viewport`". (This can affect whether a media query list matches the environment[p93].) [CSSDEVICEADAPT][p1411]

- Let *url* be the URL that *element* would fetch if it was processed normally. If there is no such URL or if it is the empty string, then do nothing. Otherwise, if url is already in the list of speculative fetch URLs[p1298], then do nothing. Otherwise, fetch url as if the element was processed normally, and add *url* to the list of speculative fetch URLs[p1298].

Each `Document`[p127] has a **list of speculative fetch URLs**, which is a list of URLs, initially empty.

To **start the speculative HTML parser** for an instance of an HTML parser *parser*:

1. Optionally, return.

   Note

   This step allows user agents to opt out of speculative HTML parsing.

2. If *parser*'s active speculative HTML parser[p1298] is not null, then stop the speculative HTML parser[p1299] for *parser*.

   Note

   This can happen when `document.write()`[p1099] writes another parser-blocking script. For simplicity, this specification always restarts speculative parsing, but user agents can implement a more efficient strategy, so long as the end result is equivalent.

3. Let *speculativeParser* be a new speculative HTML parser[p1298], with the same state as *parser*.

4. Let *speculativeDoc* be a new isomorphic representation of *parser*'s `Document`[p127], where all elements are instead speculative

mock elements[p1299]. Let *speculativeParser* parse into *speculativeDoc*.

5. Set *parser*'s active speculative HTML parser[p1298] to *speculativeParser*.
6. In parallel[p43], run *speculativeParser* until it is stopped or until it reaches the end of its input stream[p1223].

To **stop the speculative HTML parser** for an instance of an HTML parser *parser*:

1. Let *speculativeParser* be *parser*'s active speculative HTML parser[p1298].
2. If *speculativeParser* is null, then return.
3. Throw away any pending content in *speculativeParser*'s input stream[p1223], and discard any future content that would have been added to it.
4. Set *parser*'s active speculative HTML parser[p1298] to null.

The speculative HTML parser[p1298] will create speculative mock elements[p1299] instead of normal elements. DOM operations that the tree builder normally does on elements are expected to work appropriately on speculative mock elements.

A **speculative mock element** is a struct with the following items:

- A string **namespace**, corresponding to an element's namespace.
- A string **local name**, corresponding to an element's local name.
- A list **attribute list**, corresponding to an element's attribute list.
- A list **children**, corresponding to an element's children.

To **create a speculative mock element** given a *namespace*, *tagName*, and *attributes*:

1. Let *element* be a new speculative mock element[p1299].
2. Set *element*'s namespace[p1299] to *namespace*.
3. Set *element*'s local name[p1299] to *tagName*.
4. Set *element*'s attribute list[p1299] to *attributes*.
5. Set *element*'s children[p1299] to a new empty list.
6. Optionally, perform a speculative fetch[p1298] for *element*.
7. Return *element*.

When the tree builder says to insert an element into a `template`[p656] element's template contents[p657], if that is a speculative mock element[p1299], instead do nothing. URLs found speculatively inside `template`[p656] elements might themselves be templates, and must not be speculatively fetched.

13.2.9 Coercing an HTML DOM into an infoset §[p1299]

When an application uses an HTML parser[p1210] in conjunction with an XML pipeline, it is possible that the constructed DOM is not compatible with the XML tool chain in certain subtle ways. For example, an XML toolchain might not be able to represent attributes with the name `xmlns`, since they conflict with the Namespaces in XML syntax. There is also some data that the HTML parser[p1210] generates that isn't included in the DOM itself. This section specifies some rules for handling these issues.

If the XML API being used doesn't support DOCTYPEs, the tool may drop DOCTYPEs altogether.

If the XML API doesn't support attributes in no namespace that are named "`xmlns`", attributes whose names start with "`xmlns:`", or attributes in the XMLNS namespace, then the tool may drop such attributes.

The tool may annotate the output with any namespace declarations required for proper operation.

If the XML API being used restricts the allowable characters in the local names of elements and attributes, then the tool may map all element and attribute local names that the API wouldn't support to a set of names that *are* allowed, by replacing any character that

isn't supported with the uppercase letter U and the six digits of the character's code point when expressed in hexadecimal, using digits 0-9 and capital letters A-F as the symbols, in increasing numeric order.

Example

For example, the element name `foo<bar`, which can be output by the HTML parser[p1210], though it is neither a legal HTML element name nor a well-formed XML element name, would be converted into `fooU00003Cbar`, which *is* a well-formed XML element name (though it's still not legal in HTML by any means).

Example

As another example, consider the attribute `xlink:href`. Used on a MathML element, it becomes, after being adjusted[p1261], an attribute with a prefix "`xlink`" and a local name "`href`". However, used on an HTML element, it becomes an attribute with no prefix and the local name "`xlink:href`", which is not a valid NCName, and thus might not be accepted by an XML API. It could thus get converted, becoming "`xlinkU00003Ahref`".

Note

The resulting names from this conversion conveniently can't clash with any attribute generated by the HTML parser[p1210], since those are all either lowercase or those listed in the adjust foreign attributes[p1261] algorithm's table.

If the XML API restricts comments from having two consecutive U+002D HYPHEN-MINUS characters (--), the tool may insert a single U+0020 SPACE character between any such offending characters.

If the XML API restricts comments from ending in a U+002D HYPHEN-MINUS character (-), the tool may insert a single U+0020 SPACE character at the end of such comments.

If the XML API restricts allowed characters in character data, attribute values, or comments, the tool may replace any U+000C FORM FEED (FF) character with a U+0020 SPACE character, and any other literal non-XML character with a U+FFFD REPLACEMENT CHARACTER.

If the tool has no way to convey out-of-band information, then the tool may drop the following information:

- Whether the document is set to *no-quirks mode*, *limited-quirks mode*, or *quirks mode*
- The association between form controls and forms that aren't their nearest `form`[p505] element ancestor (use of the `form` element pointer[p1228] in the parser)
- The template contents[p657] of any `template`[p656] elements.

Note

The mutations allowed by this section apply after *the HTML parser[p1210]'s rules have been applied. For example, a* `<a::>` *start tag will be closed by a* `</a::>` *end tag, and never by a* `</aU00003AU00003A>` *end tag, even if the user agent is using the rules above to then generate an actual element in the DOM with the name* `aU00003AU00003A` *for that start tag.*

13.2.10 An introduction to error handling and strange cases in the parser §[p1300]

This section is non-normative.

This section examines some erroneous markup and discusses how the HTML parser[p1210] handles these cases.

13.2.10.1 Misnested tags: §[p1300]

This section is non-normative.

The most-often discussed example of erroneous markup is as follows:

```
<p>1<b>2<i>3</b>4</i>5</p>
```

The parsing of this markup is straightforward up to the "3". At this point, the DOM looks like this:

```
└html p167
  ├head p168
  └body p199
    └p p223
      ├#text: 1
      └b p287
        ├#text: 2
        └i p286
          └#text: 3
```

Here, the stack of open elements p1225 has five elements on it: html p167, body p199, p p223, b p287, and i p286. The list of active formatting elements p1227 just has two: b p287 and i p286. The insertion mode p1224 is "in body p1270".

Upon receiving the end tag token with the tag name "b", the "adoption agency algorithm p1278" is invoked. This is a simple case, in that the *formatting element* is the b p287 element, and there is no *furthest block*. Thus, the stack of open elements p1225 ends up with just three elements: html p167, body p199, and p p223, while the list of active formatting elements p1227 has just one: i p286. The DOM tree is unmodified at this point.

The next token is a character ("4"), triggers the reconstruction of the active formatting elements p1227, in this case just the i p286 element. A new i p286 element is thus created for the "4" Text node. After the end tag token for the "i" is also received, and the "5" Text node is inserted, the DOM looks as follows:

```
└html p167
  ├head p168
  └body p199
    └p p223
      ├#text: 1
      ├b p287
      │ ├#text: 2
      │ └i p286
      │   └#text: 3
      ├i p286
      │ └#text: 4
      └#text: 5
```

13.2.10.2 Misnested tags: §p1301

This section is non-normative.

A case similar to the previous one is the following:

```
<b>1<p>2</b>3</p>
```

Up to the "2" the parsing here is straightforward:

```
└html p167
  ├head p168
  └body p199
    └b p287
      ├#text: 1
      └p p223
        └#text: 2
```

The interesting part is when the end tag token with the tag name "b" is parsed.

Before that token is seen, the stack of open elements p1225 has four elements on it: html p167, body p199, b p287, and p p223. The list of active formatting elements p1227 just has the one: b p287. The insertion mode p1224 is "in body p1270".

Upon receiving the end tag token with the tag name "b", the "adoption agency algorithm p1278" is invoked, as in the previous example. However, in this case, there *is* a *furthest block*, namely the p p223 element. Thus, this time the adoption agency algorithm isn't skipped over.

The *common ancestor* is the body[p199] element. A conceptual "bookmark" marks the position of the b[p287] in the list of active formatting elements[p1227], but since that list has only one element in it, the bookmark won't have much effect.

As the algorithm progresses, *node* ends up set to the formatting element (b[p287]), and *last node* ends up set to the *furthest block* (p[p223]).

The *last node* gets appended (moved) to the *common ancestor*, so that the DOM looks like:

```
└html[p167]
  ├head[p168]
  └body[p199]
    ├b[p287]
    │└#text: 1
    └p[p223]
      └#text: 2
```

A new b[p287] element is created, and the children of the p[p223] element are moved to it:

```
└html[p167]
  ├head[p168]
  └body[p199]
    ├b[p287]
    │└#text: 1
    └p[p223]
└b[p287]
  └#text: 2
```

Finally, the new b[p287] element is appended to the p[p223] element, so that the DOM looks like:

```
└html[p167]
  ├head[p168]
  └body[p199]
    ├b[p287]
    │└#text: 1
    └p[p223]
      └b[p287]
        └#text: 2
```

The b[p287] element is removed from the list of active formatting elements[p1227] and the stack of open elements[p1225], so that when the "3" is parsed, it is appended to the p[p223] element:

```
└html[p167]
  ├head[p168]
  └body[p199]
    ├b[p287]
    │└#text: 1
    └p[p223]
      ├b[p287]
      │└#text: 2
      └#text: 3
```

13.2.10.3 Unexpected markup in tables §[p1302]

This section is non-normative.

Error handling in tables is, for historical reasons, especially strange. For example, consider the following markup:

```
<table><b><tr><td>aaa</td></tr>bbb</table>ccc
```

The highlighted b[p287] element start tag is not allowed directly inside a table like that, and the parser handles this case by placing the element *before* the table. (This is called *foster parenting*[p1258].) This can be seen by examining the DOM tree as it stands just after the table[p469] element's start tag has been seen:

```
└html[p167]
  ├head[p168]
  └body[p199]
    └table[p469]
```

...and then immediately after the b[p287] element start tag has been seen:

```
└html[p167]
  ├head[p168]
  └body[p199]
    ├b[p287]
    └table[p469]
```

At this point, the stack of open elements[p1225] has on it the elements html[p167], body[p199], table[p469], and b[p287] (in that order, despite the resulting DOM tree); the list of active formatting elements[p1227] just has the b[p287] element in it; and the insertion mode[p1224] is "in table[p1281]".

The tr[p483] start tag causes the b[p287] element to be popped off the stack and a tbody[p480] start tag to be implied; the tbody[p480] and tr[p483] elements are then handled in a rather straight-forward manner, taking the parser through the "in table body[p1285]" and "in row[p1286]" insertion modes, after which the DOM looks as follows:

```
└html[p167]
  ├head[p168]
  └body[p199]
    ├b[p287]
    └table[p469]
      └tbody[p480]
        └tr[p483]
```

Here, the stack of open elements[p1225] has on it the elements html[p167], body[p199], table[p469], tbody[p480], and tr[p483]; the list of active formatting elements[p1227] still has the b[p287] element in it; and the insertion mode[p1224] is "in row[p1286]".

The td[p484] element start tag token, after putting a td[p484] element on the tree, puts a marker[p1227] on the list of active formatting elements[p1227] (it also switches to the "in cell[p1287]" insertion mode[p1224]).

```
└html[p167]
  ├head[p168]
  └body[p199]
    ├b[p287]
    └table[p469]
      └tbody[p480]
        └tr[p483]
          └td[p484]
```

The marker[p1227] means that when the "aaa" character tokens are seen, no b[p287] element is created to hold the resulting Text node:

```
└html[p167]
  ├head[p168]
  └body[p199]
    ├b[p287]
    └table[p469]
      └tbody[p480]
        └tr[p483]
          └td[p484]
            └#text: aaa
```

The end tags are handled in a straight-forward manner; after handling them, the stack of open elements[p1225] has on it the elements html[p167], body[p199], table[p469], and tbody[p480]; the list of active formatting elements[p1227] still has the b[p287] element in it (the marker[p1227] having been removed by the "td" end tag token); and the insertion mode[p1224] is "in table body[p1285]".

Thus it is that the "bbb" character tokens are found. These trigger the "in table text[p1283]" insertion mode to be used (with the original insertion mode[p1224] set to "in table body[p1285]"). The character tokens are collected, and when the next token (the table[p469] element end tag) is seen, they are processed as a group. Since they are not all spaces, they are handled as per the "anything else" rules in the "in

table[p1281]" insertion mode, which defer to the "in body[p1270]" insertion mode but with foster parenting[p1258].

When the active formatting elements are reconstructed[p1227], a b[p287] element is created and foster parented[p1258], and then the "bbb" Text node is appended to it:

```
└html[p167]
  ├head[p168]
  └body[p199]
    ├b[p287]
    ├b[p287]
    │└#text: bbb
    └table[p469]
      └tbody[p480]
        └tr[p483]
          └td[p484]
            └#text: aaa
```

The stack of open elements[p1225] has on it the elements html[p167], body[p199], table[p469], tbody[p480], and the new b[p287] (again, note that this doesn't match the resulting tree!); the list of active formatting elements[p1227] has the new b[p287] element in it; and the insertion mode[p1224] is still "in table body[p1285]".

Had the character tokens been only ASCII whitespace instead of "bbb", then that ASCII whitespace would just be appended to the tbody[p480] element.

Finally, the table[p469] is closed by a "table" end tag. This pops all the nodes from the stack of open elements[p1225] up to and including the table[p469] element, but it doesn't affect the list of active formatting elements[p1227], so the "ccc" character tokens after the table result in yet another b[p287] element being created, this time after the table:

```
└html[p167]
  ├head[p168]
  └body[p199]
    ├b[p287]
    ├b[p287]
    │└#text: bbb
    ├table[p469]
    │└tbody[p480]
    │  └tr[p483]
    │    └td[p484]
    │      └#text: aaa
    └b[p287]
      └#text: ccc
```

13.2.10.4 Scripts that modify the page as it is being parsed §[p1304]

This section is non-normative.

Consider the following markup, which for this example we will assume is the document with URL `https://example.com/inner`, being rendered as the content of an iframe[p383] in another document with the URL `https://example.com/outer`:

```
<div id=a>
 <script>
  var div = document.getElementById('a');
  parent.document.body.appendChild(div);
 </script>
 <script>
  alert(document.URL);
 </script>
</div>
<script>
 alert(document.URL);
</script>
```

Up to the first "script" end tag, before the script is parsed, the result is relatively straightforward:

```
└html[p167]
  ├head[p168]
  └body[p199]
    └div[p251] id[p151]="a"
      ├#text:
      └script[p638]
        └#text: var div = document.getElementById('a'); parent.document.body.appendChild(div);
```

After the script is parsed, though, the div[p251] element and its child script[p638] element are gone:

```
└html[p167]
  ├head[p168]
  └body[p199]
```

They are, at this point, in the Document[p127] of the aforementioned outer browsing context[p961]. However, the stack of open elements[p1225] *still contains the* div[p251] *element*.

Thus, when the second script[p638] element is parsed, it is inserted *into the outer* Document[p127] *object*.

Those parsed into different Document[p127]s than the one the parser was created for do not execute, so the first alert does not show.

Once the div[p251] element's end tag is parsed, the div[p251] element is popped off the stack, and so the next script[p638] element is in the inner Document[p127]:

```
└html[p167]
  ├head[p168]
  └body[p199]
    └script[p638]
      └#text: alert(document.URL);
```

This script does execute, resulting in an alert that says "https://example.com/inner".

13.2.10.5 The execution of scripts that are moving across multiple documents §[p1305]

This section is non-normative.

Elaborating on the example in the previous section, consider the case where the second script[p638] element is an external script (i.e. one with a src[p640] attribute). Since the element was not in the parser's Document[p127] when it was created, that external script is not even downloaded.

In a case where a script[p638] element with a src[p640] attribute is parsed normally into its parser's Document[p127], but while the external script is being downloaded, the element is moved to another document, the script continues to download, but does not execute.

Note

In general, moving script[p638] *elements between* Document[p127]*s is considered a bad practice.*

13.2.10.6 Unclosed formatting elements §[p1305]

This section is non-normative.

The following markup shows how nested formatting elements (such as b[p287]) get collected and continue to be applied even as the elements they are contained in are closed, but that excessive duplicates are thrown away.

```
<!DOCTYPE html>
<p><b class=x><b class=x><b><b class=x><b class=x><b>X
<p>X
<p><b><b class=x><b>X
```

```
<p></b></b></b></b></b></b>X
```

The resulting DOM tree is as follows:

```
├DOCTYPE: html
└html p167
  ├head p168
  └body p199
    ├p p223
    │└b p287 class p151="x"
    │ └b p287 class p151="x"
    │  └b p287
    │   └b p287 class p151="x"
    │    └b p287 class p151="x"
    │     └b p287
    │      └#text: X
    ├p p223
    │└b p287 class p151="x"
    │ └b p287
    │  └b p287 class p151="x"
    │   └b p287 class p151="x"
    │    └b p287
    │     └#text: X
    ├p p223
    │└b p287 class p151="x"
    │ └b p287
    │  └b p287 class p151="x"
    │   └b p287 class p151="x"
    │    └b p287
    │     └b p287
    │      └b p287 class p151="x"
    │       └b p287
    │        └#text: X
    └p p223
     └#text: X
```

Note how the second p p223 element in the markup has no explicit b p287 elements, but in the resulting DOM, up to three of each kind of formatting element (in this case three b p287 elements with the class attribute, and two unadorned b p287 elements) get reconstructed before the element's "X".

Also note how this means that in the final paragraph only six b p287 end tags are needed to completely clear the list of active formatting elements p1227, even though nine b p287 start tags have been seen up to this point.

13.3 Serializing HTML fragments §p1306

For the purposes of the following algorithm, an element **serializes as void** if its element type is one of the void elements p1199, or is basefont p1363, bgsound p1362, frame p1369, keygen p1362, or param p1362.

The following steps form the **HTML fragment serialization algorithm**. The algorithm takes as input a DOM Element, Document p127, or DocumentFragment referred to as *the node*, and returns a string.

Note

This algorithm serializes the children *of the node being serialized, not the node itself.*

1. If *the node* serializes as void p1306, then return the empty string.
2. Let *s* be a string, and initialize it to the empty string.
3. If *the node* is a template p656 element, then let *the node* instead be the template p656 element's template contents p657 (a

`DocumentFragment` node).

4. For each child node of *the node*, in tree order, run the following steps:

    1. Let *current node* be the child node being processed.

    2. Append the appropriate string from the following list to *s*:

    ↪ **If *current node* is an `Element`**

    If *current node* is an element in the HTML namespace, the MathML namespace, or the SVG namespace, then let *tagname* be *current node*'s local name. Otherwise, let *tagname* be *current node*'s qualified name.

    Append a U+003C LESS-THAN SIGN character (<), followed by *tagname*.

    Note

    For HTML elements[p45] created by the HTML parser[p1210] or `createElement()`, tagname *will be lowercase.*

    If *current node*'s `is` value is not null, and the element does not have an `is`[p742] attribute in its attribute list, then append the string " `is=""`", followed by *current node*'s `is` value escaped as described below[p1310] in *attribute mode*, followed by a U+0022 QUOTATION MARK character (").

    For each attribute that the element has, append a U+0020 SPACE character, the attribute's serialized name as described below[p1307], a U+003D EQUALS SIGN character (=), a U+0022 QUOTATION MARK character ("), the attribute's value, escaped as described below[p1310] in *attribute mode*, and a second U+0022 QUOTATION MARK character (").

    An **attribute's serialized name** for the purposes of the previous paragraph must be determined as follows:

    ↪ **If the attribute has no namespace**
    The attribute's serialized name is the attribute's local name.

    Note

    For attributes on HTML elements[p45] set by the HTML parser[p1210] or by `setAttribute()`, the local name will be lowercase.

    ↪ **If the attribute is in the XML namespace**
    The attribute's serialized name is the string "`xml:`" followed by the attribute's local name.

    ↪ **If the attribute is in the XMLNS namespace and the attribute's local name is `xmlns`**
    The attribute's serialized name is the string "`xmlns`".

    ↪ **If the attribute is in the XMLNS namespace and the attribute's local name is not `xmlns`**
    The attribute's serialized name is the string "`xmlns:`" followed by the attribute's local name.

    ↪ **If the attribute is in the XLink namespace**
    The attribute's serialized name is the string "`xlink:`" followed by the attribute's local name.

    ↪ **If the attribute is in some other namespace**
    The attribute's serialized name is the attribute's qualified name.

    While the exact order of attributes is implementation-defined, and may depend on factors such as the order that the attributes were given in the original markup, the sort order must be stable, such that consecutive invocations of this algorithm serialize an element's attributes in the same order.

    Append a U+003E GREATER-THAN SIGN character (>).

    If *current node* serializes as void[p1306], then continue on to the next child node at this point.

    Append the value of running the HTML fragment serialization algorithm[p1306] on the *current node* element (thus recursing into this algorithm for that element), followed by a U+003C LESS-THAN SIGN character (<), a U+002F SOLIDUS character (/), *tagname* again, and finally a U+003E GREATER-THAN SIGN character (>).

↪ **If *current node* is a Text node**

If the parent of *current node* is a style[p195], script[p638], xmp[p1363], iframe[p383], noembed[p1362], noframes[p1362], or plaintext[p1362] element, or if the parent of *current node* is a noscript[p654] element and scripting is enabled[p1039] for the node, then append the value of *current node*'s data literally.

Otherwise, append the value of *current node*'s data, escaped as described below[p1310].

↪ **If *current node* is a Comment**

Append the literal string "`<!--`" (U+003C LESS-THAN SIGN, U+0021 EXCLAMATION MARK, U+002D HYPHEN-MINUS, U+002D HYPHEN-MINUS), followed by the value of *current node*'s data, followed by the literal string "`-->`" (U+002D HYPHEN-MINUS, U+002D HYPHEN-MINUS, U+003E GREATER-THAN SIGN).

↪ **If *current node* is a ProcessingInstruction**

Append the literal string "`<?`" (U+003C LESS-THAN SIGN, U+003F QUESTION MARK), followed by the value of *current node*'s `target` IDL attribute, followed by a single U+0020 SPACE character, followed by the value of *current node*'s data, followed by a single U+003E GREATER-THAN SIGN character (>).

↪ **If *current node* is a DocumentType**

Append the literal string "`<!DOCTYPE`" (U+003C LESS-THAN SIGN, U+0021 EXCLAMATION MARK, U+0044 LATIN CAPITAL LETTER D, U+004F LATIN CAPITAL LETTER O, U+0043 LATIN CAPITAL LETTER C, U+0054 LATIN CAPITAL LETTER T, U+0059 LATIN CAPITAL LETTER Y, U+0050 LATIN CAPITAL LETTER P, U+0045 LATIN CAPITAL LETTER E), followed by a space (U+0020 SPACE), followed by the value of *current node*'s name, followed by the literal string ">" (U+003E GREATER-THAN SIGN).

5. Return *s*.

⚠Warning!

It is possible that the output of this algorithm, if parsed with an HTML parser[p1210], will not return the original tree structure. Tree structures that do not roundtrip a serialize and reparse step can also be produced by the HTML parser[p1210] itself, although such cases are typically non-conforming.

Example

For instance, if a textarea[p570] element to which a `Comment` node has been appended is serialized and the output is then reparsed, the comment will end up being displayed in the text control. Similarly, if, as a result of DOM manipulation, an element contains a comment that contains the literal string "`-->`", then when the result of serializing the element is parsed, the comment will be truncated at that point and the rest of the comment will be interpreted as markup. More examples would be making a script[p638] element contain a Text node with the text string "`</script>`", or having a p[p223] element that contains a ul[p234] element (as the ul[p234] element's start tag[p1200] would imply the end tag for the p[p223]).

This can enable cross-site scripting attacks. An example of this would be a page that lets the user enter some font family names that are then inserted into a CSS style[p195] block via the DOM and which then uses the innerHTML IDL attribute to get the HTML serialization of that style[p195] element: if the user enters "`</style><script>attack</script>`" as a font family name, innerHTML will return markup that, if parsed in a different context, would contain a script[p638] node, even though no script[p638] node existed in the original DOM.

Example

For example, consider the following markup:

```
<form id="outer"><div></form><form id="inner"><input>
```

This will be parsed into:

```
└html[p167]
  ├head[p168]
  └body[p199]
    └form[p505] id[p151]="outer"
      └div[p251]
        └form[p505] id[p151]="inner"
          └input[p512]
```

The input[p512] element will be associated with the inner form[p505] element. Now, if this tree structure is serialized and reparsed, the `<form id="inner">` start tag will be ignored, and so the input[p512] element will be associated with the outer form[p505] element instead.

```
<html><head></head><body><form id="outer"><div><form
id="inner"><input></form></div></form></body></html>
```

```
└html[p167]
  ├head[p168]
  └body[p199]
    └form[p505] id[p151]="outer"
      └div[p251]
        └input[p512]
```

Example

As another example, consider the following markup:

```
<a><table><a>
```

This will be parsed into:

```
└html[p167]
  ├head[p168]
  └body[p199]
    └a[p252]
      ├a[p252]
      └table[p469]
```

That is, the a[p252] elements are nested, because the second a[p252] element is foster parented[p1258]. After a serialize-reparse roundtrip, the a[p252] elements and the table[p469] element would all be siblings, because the second `<a>` start tag implicitly closes the first a[p252] element.

```
<html><head></head><body><a><a></a><table></table></a></body></html>
```

```
└html[p167]
  ├head[p168]
  └body[p199]
    ├a[p252]
    ├a[p252]
    └table[p469]
```

For historical reasons, this algorithm does not round-trip an initial U+000A LINE FEED (LF) character in pre[p228], textarea[p570], or listing[p1362] elements, even though (in the first two cases) the markup being round-tripped can be conforming. The HTML parser[p1210] will drop such a character during parsing, but this algorithm does *not* serialize an extra U+000A LINE FEED (LF) character.

Example

For example, consider the following markup:

```
<pre>

Hello.</pre>
```

When this document is first parsed, the pre[p228] element's child text content starts with a single newline character. After a serialize-reparse roundtrip, the pre[p228] element's child text content is simply "`Hello.`".

Because of the special role of the is[p742] attribute in signaling the creation of customized built-in elements[p742], in that it provides a mechanism for parsed HTML to set the element's is value, we special-case its handling during serialization. This ensures that an element's is value is preserved through serialize-parse roundtrips.

Example

When creating a customized built-in element[p742] via the parser, a developer uses the `is`[p742] attribute directly; in such cases serialize-parse roundtrips work fine.

```
<script>
window.SuperP = class extends HTMLParagraphElement {};
customElements.define("super-p", SuperP, { extends: "p" });
</script>

<div id="container"><p is="super-p">Superb!</p></div>

<script>
console.log(container.innerHTML); // <p is="super-p">
container.innerHTML = container.innerHTML;
console.log(container.innerHTML); // <p is="super-p">
console.assert(container.firstChild instanceof SuperP);
</script>
```

But when creating a customized built-in element via its constructor[p742] or via `createElement()`, the `is`[p742] attribute is not added. Instead, the `is` value (which is what the custom elements machinery uses) is set without intermediating through an attribute.

```
<script>
container.innerHTML = "";
const p = document.createElement("p", { is: "super-p" });
container.appendChild(p);

// The is attribute is not present in the DOM:
console.assert(!p.hasAttribute("is"));

// But the element is still a super-p:
console.assert(p instanceof SuperP);
</script>
```

To ensure that serialize-parse roundtrips still work, the serialization process explicitly writes out the element's `is` value as an `is`[p742] attribute:

```
<script>
console.log(container.innerHTML); // <p is="super-p">
container.innerHTML = container.innerHTML;
console.log(container.innerHTML); // <p is="super-p">
console.assert(container.firstChild instanceof SuperP);
</script>
```

Escaping a string (for the purposes of the algorithm above) consists of running the following steps:

1. Replace any occurrence of the "&" character by the string "&".
2. Replace any occurrences of the U+00A0 NO-BREAK SPACE character by the string " ".
3. If the algorithm was invoked in the *attribute mode*, replace any occurrences of the "" character by the string """.
4. If the algorithm was *not* invoked in the *attribute mode*, replace any occurrences of the "<" character by the string "<", and any occurrences of the ">" character by the string ">".

13.4 Parsing HTML fragments §[p1310]

The following steps form the **HTML fragment parsing algorithm**. The algorithm takes as input an `Element` node, referred to as the ***context*** element, which gives the context for the parser, as well as *input*, a string to parse, and returns a list of zero or more nodes.

Note

Parts marked **fragment case** *in algorithms in the parser section are parts that only occur if the parser was created for the purposes of this algorithm. The algorithms have been annotated with such markings for informational purposes only; such markings have no normative weight. If it is possible for a condition described as a fragment case[p1311] to occur even when the parser wasn't created for the purposes of handling this algorithm, then that is an error in the specification.*

1. Create a new `Document`[p127] node, and mark it as being an HTML document.

2. If the node document of the *context*[p1310] element is in quirks mode, then let the `Document`[p127] be in quirks mode. Otherwise, the node document of the *context*[p1310] element is in limited-quirks mode, then let the `Document`[p127] be in limited-quirks mode. Otherwise, leave the `Document`[p127] in no-quirks mode.

3. Create a new HTML parser[p1210], and associate it with the just created `Document`[p127] node.

4. Set the state of the HTML parser[p1210]'s tokenization[p1229] stage as follows, switching on the *context*[p1310] element:

   ↪ **`title`**[p169]
   ↪ **`textarea`**[p570]
   Switch the tokenizer to the RCDATA state[p1230].

   ↪ **`style`**[p195]
   ↪ **`xmp`**[p1363]
   ↪ **`iframe`**[p383]
   ↪ **`noembed`**[p1362]
   ↪ **`noframes`**[p1362]
   Switch the tokenizer to the RAWTEXT state[p1230].

   ↪ **`script`**[p638]
   Switch the tokenizer to the script data state[p1230].

   ↪ **`noscript`**[p654]
   If the scripting flag[p1228] is enabled, switch the tokenizer to the RAWTEXT state[p1230]. Otherwise, leave the tokenizer in the data state[p1229].

   ↪ **`plaintext`**[p1362]
   Switch the tokenizer to the PLAINTEXT state[p1231].

   ↪ **Any other element**
   Leave the tokenizer in the data state[p1229].

   Note

   For performance reasons, an implementation that does not report errors and that uses the actual state machine described in this specification directly could use the PLAINTEXT state instead of the RAWTEXT and script data states where those are mentioned in the list above. Except for rules regarding parse errors, they are equivalent, since there is no appropriate end tag token[p1229] in the fragment case, yet they involve far fewer state transitions.

5. Let *root* be a new `html`[p167] element with no attributes.

6. Append the element *root* to the `Document`[p127] node created above.

7. Set up the parser's stack of open elements[p1225] so that it contains just the single element *root*.

8. If the *context*[p1310] element is a `template`[p656] element, push "in template[p1290]" onto the stack of template insertion modes[p1224] so that it is the new current template insertion mode[p1224].

9. Create a start tag token whose name is the local name of *context*[p1310] and whose attributes are the attributes of *context*[p1310].

   Let this start tag token be the start tag token of the *context*[p1310] node, e.g. for the purposes of determining if it is an HTML integration point[p1257].

10. Reset the parser's insertion mode appropriately[p1224].

    Note

    The parser will reference the context[p1310] *element as part of that algorithm.*

11. Set the parser's form element pointer[p1228] to the nearest node to the *context*[p1310] element that is a form[p505] element (going straight up the ancestor chain, and including the element itself, if it is a form[p505] element), if any. (If there is no such form[p505] element, the form element pointer[p1228] keeps its initial value, null.)

12. Place the *input* into the input stream[p1223] for the HTML parser[p1210] just created. The encoding confidence[p1217] is *irrelevant*.

13. Start the parser and let it run until it has consumed all the characters just inserted into the input stream.

14. Return the child nodes of *root*, in tree order.

13.5 Named character references §[p1312]

This table lists the character reference names that are supported by HTML, and the code points to which they refer. It is referenced by the previous sections.

Note

It is intentional, for legacy compatibility, that many code points have multiple character reference names. For example, some appear both with and without the trailing semicolon, or with different capitalizations.

This data is also available as a JSON file.

The glyphs displayed above are non-normative. Refer to Unicode for formal definitions of the characters listed above.

Note

The character reference names originate from XML Entity Definitions for Characters, *though only the above is considered normative. [XMLENTITY]p1419*

Note

This list is static and will not be expanded or changed in the future.

14 The XML syntax §p1321

Note

This section only describes the rules for XML resources. Rules for `text/html`p1380 *resources are discussed in the section above entitled "The HTML syntax*p1198*".*

14.1 Writing documents in the XML syntax §p1321

Note

The XML syntax for HTML was formerly referred to as "XHTML", but this specification does not use that term (among other reasons, because no such term is used for the HTML syntaxes of MathML and SVG).

The syntax for XML is defined in *XML* and *Namespaces in XML*. [XML]p1419 [XMLNS]p1419

This specification does not define any syntax-level requirements beyond those defined for XML proper.

XML documents may contain a `DOCTYPE` if desired, but this is not required to conform to this specification. This specification does not define a public or system identifier, nor provide a formal DTD.

Note

According to XML*, XML processors are not guaranteed to process the external DTD subset referenced in the DOCTYPE. This means, for example, that using entity references for characters in XML documents is unsafe if they are defined in an external file (except for* `<`, `>`, `&`, `"`, *and* `'`*).*

14.2 Parsing XML documents §p1321

This section describes the relationship between XML and the DOM, with a particular emphasis on how this interacts with HTML.

An **XML parser**, for the purposes of this specification, is a construct that follows the rules given in *XML* to map a string of bytes or characters into a `Document`p127 object.

Note

At the time of writing, no such rules actually exist.

An XML parserp1321 is either associated with a `Document`p127 object when it is created, or creates one implicitly.

This `Document`p127 must then be populated with DOM nodes that represent the tree structure of the input passed to the parser, as defined by *XML*, *Namespaces in XML*, and *DOM*. When creating DOM nodes representing elements, the create an element for a tokenp1258 algorithm or some equivalent that operates on appropriate XML data structures must be used, to ensure the proper element interfaces are created and that custom elementsp742 are set up correctly.

DOM mutation events must not fire for the operations that the XML parserp1321 performs on the `Document`p127's tree, but the user agent must act as if elements and attributes were individually appended and set respectively so as to trigger rules in this specification regarding what happens when an element is inserted into a document or has its attributes set, and *DOM*'s requirements regarding mutation observers mean that mutation observers *are* fired (unlike mutation events). [XML]p1419 [XMLNS]p1419 [DOM]p1412 [UIEVENTS]p1417

Between the time an element's start tag is parsed and the time either the element's end tag is parsed or the parser detects a well-formedness error, the user agent must act as if the element was in a stack of open elementsp1225.

Note

This is used by various elements to only start certain processes once they are popped off of the stack of open elements[p1225].

This specification provides the following additional information that user agents should use when retrieving an external entity: the public identifiers given in the following list all correspond to the URL given by this link. (This URL is a DTD containing the entity declarations for the names listed in the named character references[p1312] section.) [XML][p1419]

- `-//W3C//DTD XHTML 1.0 Transitional//EN`
- `-//W3C//DTD XHTML 1.1//EN`
- `-//W3C//DTD XHTML 1.0 Strict//EN`
- `-//W3C//DTD XHTML 1.0 Frameset//EN`
- `-//W3C//DTD XHTML Basic 1.0//EN`
- `-//W3C//DTD XHTML 1.1 plus MathML 2.0//EN`
- `-//W3C//DTD XHTML 1.1 plus MathML 2.0 plus SVG 1.1//EN`
- `-//W3C//DTD MathML 2.0//EN`
- `-//WAPFORUM//DTD XHTML Mobile 1.0//EN`

Furthermore, user agents should attempt to retrieve the above external entity's content when one of the above public identifiers is used, and should not attempt to retrieve any other external entity's content.

Note

This is not strictly a violation[p28] of XML, but it does contradict the spirit of XML's requirements. This is motivated by a desire for user agents to all handle entities in an interoperable fashion without requiring any network access for handling external subsets. [XML][p1419]

XML parsers can be invoked with **XML scripting support enabled** or **XML scripting support disabled**. Except where otherwise specified, XML parsers are invoked with XML scripting support enabled[p1322].

When an XML parser[p1321] with XML scripting support enabled[p1322] creates a `script`[p638] element, it must have its parser document[p645] set and its force async[p645] set to false. If the parser was created as part of the XML fragment parsing algorithm[p1324], then the element's already started[p645] must be set to true. When the element's end tag is subsequently parsed, the user agent must perform a microtask checkpoint[p1077], and then prepare[p646] the `script`[p638] element. If this causes there to be a pending parsing-blocking script[p650], then the user agent must run the following steps:

1. Block this instance of the XML parser[p1321], such that the event loop[p1071] will not run tasks[p1071] that invoke it.
2. Spin the event loop[p1078] until the parser's `Document`[p127] has no style sheet that is blocking scripts[p199] and the pending parsing-blocking script[p650]'s ready to be parser-executed[p645] is true.
3. Unblock this instance of the XML parser[p1321], such that tasks[p1071] that invoke it can again be run.
4. Execute the script element[p650] given by the pending parsing-blocking script[p650].
5. Set the pending parsing-blocking script[p650] to null.

Note

Since the `document.write()`[p1099] API is not available for XML documents, much of the complexity in the HTML parser[p1210] is not needed in the XML parser[p1321].

Note

When the XML parser[p1321] has XML scripting support disabled[p1322], none of this happens.

When an XML parser[p1321] would append a node to a `template`[p656] element, it must instead append it to the `template`[p656] element's template contents[p657] (a `DocumentFragment` node).

Note

This is a willful violation[p28] of XML; unfortunately, XML is not formally extensible in the manner that is needed for `template`[p656] processing. [XML][p1419]

When an XML parser[p1321] creates a `Node` object, its node document must be set to the node document of the node into which the newly created node is to be inserted.

Certain algorithms in this specification **spoon-feed the parser** characters one string at a time. In such cases, the XML parser[p1321]

must act as it would have if faced with a single string consisting of the concatenation of all those characters.

When an XML parser[p1321] reaches the end of its input, it must stop parsing[p1296], following the same rules as the HTML parser[p1210]. An XML parser[p1321] can also be aborted[p1297], which must again be done in the same way as for an HTML parser[p1210].

For the purposes of conformance checkers, if a resource is determined to be in the XML syntax[p1321], then it is an XML document.

14.3 Serializing XML fragments §[p1323]

The **XML fragment serialization algorithm** for a `Document`[p127] or `Element` node either returns a fragment of XML that represents that node or throws an exception.

For `Document`[p127]s, the algorithm must return a string in the form of a document entity, if none of the error cases below apply.

For `Element`s, the algorithm must return a string in the form of an internal general parsed entity, if none of the error cases below apply.

In both cases, the string returned must be XML namespace-well-formed and must be an isomorphic serialization of all of that node's relevant child nodes[p1323], in tree order. User agents may adjust prefixes and namespace declarations in the serialization (and indeed might be forced to do so in some cases to obtain namespace-well-formed XML). User agents may use a combination of regular text and character references to represent `Text` nodes in the DOM.

A node's **relevant child nodes** are those that apply given the following rules:

For `template`[p656] elements

The relevant child nodes[p1323] are the child nodes of the `template`[p656] element's template contents[p657], if any.

For all other nodes

The relevant child nodes[p1323] are the child nodes of node itself, if any.

For `Element`s, if any of the elements in the serialization are in no namespace, the default namespace in scope for those elements must be explicitly declared as the empty string. (This doesn't apply in the `Document`[p127] case.) [XML][p1419] [XMLNS][p1419]

For the purposes of this section, an internal general parsed entity is considered XML namespace-well-formed if a document consisting of an element with no namespace declarations whose contents are the internal general parsed entity would itself be XML namespace-well-formed.

If any of the following error cases are found in the DOM subtree being serialized, then the algorithm must throw an `"InvalidStateError"` `DOMException` instead of returning a string:

- A `Document`[p127] node with no child element nodes.
- A `DocumentType` node that has an external subset public identifier that contains characters that are not matched by the XML `PubidChar` production. [XML][p1419]
- A `DocumentType` node that has an external subset system identifier that contains both a U+0022 QUOTATION MARK (") and a U+0027 APOSTROPHE (') or that contains characters that are not matched by the XML `Char` production. [XML][p1419]
- A node with a local name containing a U+003A COLON (:).
- A node with a local name that does not match the XML `Name` production. [XML][p1419]
- An `Attr` node with no namespace whose local name is the lowercase string "`xmlns`". [XMLNS][p1419]
- An `Element` node with two or more attributes with the same local name and namespace.
- An `Attr` node, `Text` node, `Comment` node, or `ProcessingInstruction` node whose data contains characters that are not matched by the XML `Char` production. [XML][p1419]
- A `Comment` node whose data contains two adjacent U+002D HYPHEN-MINUS characters (-) or ends with such a character.
- A `ProcessingInstruction` node whose target name is an ASCII case-insensitive match for the string "`xml`".
- A `ProcessingInstruction` node whose target name contains a U+003A COLON (:).
- A `ProcessingInstruction` node whose data contains the string "`?>`".

Note

These are the only ways to make a DOM unserialisable. The DOM enforces all the other XML constraints; for example, trying to append two elements to a `Document`[p127] *node will throw a* `"HierarchyRequestError"` `DOMException`.

14.4 Parsing XML fragments §[p1324]

The **XML fragment parsing algorithm** either returns a `Document`[p127] or throws a `"SyntaxError"` `DOMException`. Given a string *input* and a context element *context*[p1310], the algorithm is as follows:

1. Create a new XML parser[p1321].
2. Feed the parser[p1322] just created the string corresponding to the start tag of the *context*[p1310] element, declaring all the namespace prefixes that are in scope on that element in the DOM, as well as declaring the default namespace (if any) that is in scope on that element in the DOM.

   A namespace prefix is in scope if the DOM `lookupNamespaceURI()` method on the element would return a non-null value for that prefix.

   The default namespace is the namespace for which the DOM `isDefaultNamespace()` method on the element would return true.

   Note

   No `DOCTYPE` *is passed to the parser, and therefore no external subset is referenced, and therefore no entities will be recognized.*
3. Feed the parser[p1322] just created the string *input*.
4. Feed the parser[p1322] just created the string corresponding to the end tag of the *context*[p1310] element.
5. If there is an XML well-formedness or XML namespace well-formedness error, then throw a `"SyntaxError"` `DOMException`.
6. If the document element of the resulting `Document`[p127] has any sibling nodes, then throw a `"SyntaxError"` `DOMException`.
7. Return the child nodes of the document element of the resulting `Document`[p127], in tree order.

15 Rendering §[p1325]

User agents are not required to present HTML documents in any particular way. However, this section provides a set of suggestions for rendering HTML documents that, if followed, are likely to lead to a user experience that closely resembles the experience intended by the documents' authors. So as to avoid confusion regarding the normativity of this section, "must" has not been used. Instead, the term "expected" is used to indicate behavior that will lead to this experience. For the purposes of conformance for user agents designated as supporting the suggested default rendering[p48], the term "expected" in this section has the same conformance implications as "must".

15.1 Introduction §[p1325]

The suggestions in this section are generally expressed in CSS terms. User agents are expected to either support CSS, or translate from the CSS rules given in this section to approximations for other presentation mechanisms.

In the absence of style-layer rules to the contrary (e.g. author style sheets), user agents are expected to render an element so that it conveys to the user the meaning that the element represents[p138], as described by this specification.

The suggestions in this section generally assume a visual output medium with a resolution of 96dpi or greater, but HTML is intended to apply to multiple media (it is a *media-independent* language). User agent implementers are encouraged to adapt the suggestions in this section to their target media.

An element is **being rendered** if it has any associated CSS layout boxes, SVG layout boxes, or some equivalent in other styling languages.

Note

Just being off-screen does not mean the element is not being rendered[p1325]. The presence of the `hidden`[p805] attribute normally means the element is not being rendered[p1325], though this might be overridden by the style sheets.

Note

The fully active[p966] state does not affect whether an element is being rendered[p1325] or not. Even if a document is not fully active[p966] and not shown at all to the user, elements within it can still qualify as "being rendered".

An element is said to **intersect the viewport** when it is being rendered[p1325] and its associated CSS layout box intersects the viewport.

Note

Similar to the being rendered[p1325] state, elements in non-fully active[p966] documents can still intersect the viewport[p1325]. The viewport is not shared between documents and might not always be shown to the user, so an element in a non-fully active[p966] document can still intersect the viewport associated with its document.

Note

This specification does not define the precise timing for when the intersection is tested, but it is suggested that the timing match that of the Intersection Observer API. [INTERSECTIONOBSERVER][p1413]

User agents that do not honor author-level CSS style sheets are nonetheless expected to act as if they applied the CSS rules given in these sections in a manner consistent with this specification and the relevant CSS and Unicode specifications. [CSS][p1411] [UNICODE][p1417] [BIDI][p1410]

Note

This is especially important for issues relating to the 'display', 'unicode-bidi', and 'direction' properties.

15.2 The CSS user agent style sheet and presentational hints §p1326

The CSS rules given in these subsections are, except where otherwise specified, expected to be used as part of the user-agent level style sheet defaults for all documents that contain HTML elementsp45.

Some rules are intended for the author-level zero-specificity presentational hints part of the CSS cascade; these are explicitly called out as **presentational hints**.

When the text below says that an attribute *attribute* on an element *element* **maps to the pixel length property** (or properties) *properties*, it means that if *element* has an attribute *attribute* set, and parsing that attribute's value using the rules for parsing non-negative integersp74 doesn't generate an error, then the user agent is expected to use the parsed value as a pixel length for a presentational hintp1326 for *properties*.

When the text below says that an attribute *attribute* on an element *element* **maps to the dimension property** (or properties) *properties*, it means that if *element* has an attribute *attribute* set, and parsing that attribute's value using the rules for parsing dimension valuesp76 doesn't generate an error, then the user agent is expected to use the parsed dimension as the value for a presentational hintp1326 for *properties*, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension was a percentage.

When the text below says that an attribute *attribute* on an element *element* **maps to the dimension property (ignoring zero)** (or properties) *properties*, it means that if *element* has an attribute *attribute* set, and parsing that attribute's value using the rules for parsing nonzero dimension valuesp77 doesn't generate an error, then the user agent is expected to use the parsed dimension as the value for a presentational hintp1326 for *properties*, with the value given as a pixel length if the dimension was a length, and with the value given as a percentage if the dimension was a percentage.

When the text below says that a pair of attributes *w* and *h* on an element *element* **map to the aspect-ratio property**, it means that if *element* has both attributes *w* and *h*, and parsing those attributes' values using the rules for parsing non-negative integersp74 doesn't generate an error for either, then the user agent is expected to use the parsed integers as a presentational hintp1326 for the 'aspect-ratio' property of the form `auto w / h`.

When the text below says that a pair of attributes *w* and *h* on an element *element* **map to the aspect-ratio property (using dimension rules)**, it means that if *element* has both attributes *w* and *h*, and parsing those attributes' values using the rules for parsing dimension valuesp76 doesn't generate an error or return a percentage for either, then the user agent is expected to use the parsed dimensions as a presentational hintp1326 for the 'aspect-ratio' property of the form `auto w / h`.

When a user agent is to **align descendants** of a node, the user agent is expected to align only those descendants that have both their 'margin-inline-start' and 'margin-inline-end' properties computing to a value other than 'auto', that are over-constrained and that have one of those two margins with a used value forced to a greater value, and that do not themselves have an applicable `align` attribute. When multiple elements are to alignp1326 a particular descendant, the most deeply nested such element is expected to override the others. Aligned elements are expected to be aligned by having the used values of their margins on the line-left and line-right sides be set accordingly. [CSSLOGICAL]p1412 [CSSWM]p1412

15.3 Non-replaced elements §p1326

15.3.1 Hidden elements §p1326

```
CSS
@namespace "http://www.w3.org/1999/xhtml";

area, base, basefont, datalist, head, link, meta, noembed,
noframes, param, rp, script, style, template, title {
  display: none;
}

[hidden]:not([hidden=until-found i]) {
  display: none;
}

[hidden=until-found i]:not(embed) {
  content-visibility: hidden;
```

```
}

embed[hidden] { display: inline; height: 0; width: 0; }

input[type=hidden i] { display: none !important; }

@media (scripting) {
  noscript { display: none !important; }
}
```

15.3.2 The page §[p13 27]

```
CSS
@namespace "http://www.w3.org/1999/xhtml";

html, body { display: block; }
```

For each property in the table below, given a body[p199] element, the first attribute that exists maps to the pixel length property[p1326] on the body[p199] element. If none of the attributes for a property are found, or if the value of the attribute that was found cannot be parsed successfully, then a default value of 8px is expected to be used for that property instead.

Property	Source
'margin-top'	The body[p199] element's marginheight[p1366] attribute
	The body[p199] element's topmargin[p1366] attribute
	The body[p199] element's container frame element[p1327]'s marginheight[p1366] attribute
'margin-right'	The body[p199] element's marginwidth[p1366] attribute
	The body[p199] element's rightmargin[p1366] attribute
	The body[p199] element's container frame element[p1327]'s marginwidth[p1366] attribute
'margin-bottom'	The body[p199] element's marginheight[p1366] attribute
	The body[p199] element's bottommargin[p1366] attribute
	The body[p199] element's container frame element[p1327]'s marginheight[p1366] attribute
'margin-left'	The body[p199] element's marginwidth[p1366] attribute
	The body[p199] element's leftmargin[p1366] attribute
	The body[p199] element's container frame element[p1327]'s marginwidth[p1366] attribute

If the body[p199] element's node document's node navigable[p953] is a child navigable[p955], and the container[p955] of that navigable[p952] is a frame[p1369] or iframe[p383] element, then the **container frame element** of the body[p199] element is that frame[p1369] or iframe[p383] element. Otherwise, there is no container frame element[p1327].

⚠Warning!

The above requirements imply that a page can change the margins of another page (including one from another origin[p869]) using, for example, an iframe[p383]. This is potentially a security risk, as it might in some cases allow an attack to contrive a situation in which a page is rendered not as the author intended, possibly for the purposes of phishing or otherwise misleading the user.

If a Document[p127]'s node navigable[p953] is a child navigable[p955], then it is expected to be positioned and sized to fit inside the content box of the container[p955] of that navigable[p952]. If the container[p955] is not being rendered[p1325], the navigable[p952] is expected to have a viewport with zero width and zero height.

If a Document[p127]'s node navigable[p953] is a child navigable[p955], the container[p955] of that navigable[p952] is a frame[p1369] or iframe[p383] element, that element has a `scrolling` attribute, and that attribute's value is an ASCII case-insensitive match for the string "`off`", "`noscroll`", or "`no`", then the user agent is expected to prevent any scrollbars from being shown for the viewport of the Document[p127]'s node navigable[p953], regardless of the 'overflow' property that applies to that viewport.

When a body[p199] element has a background[p1367] attribute set to a non-empty value, the new value is expected to be parsed[p95] relative

to the element's node document, and if this is successful, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the element's 'background-image' property to the resulting URL string[p95].

When a body[p199] element has a bgcolor[p1366] attribute set, the new value is expected to be parsed using the rules for parsing a legacy color value[p91], and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the element's 'background-color' property to the resulting color.

When a body[p199] element has a text[p1366] attribute, its value is expected to be parsed using the rules for parsing a legacy color value[p91], and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the element's 'color' property to the resulting color.

When a body[p199] element has a link[p1366] attribute, its value is expected to be parsed using the rules for parsing a legacy color value[p91], and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the 'color' property of any element in the Document[p127] matching the :link[p765] pseudo-class to the resulting color.

When a body[p199] element has a vlink[p1366] attribute, its value is expected to be parsed using the rules for parsing a legacy color value[p91], and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the 'color' property of any element in the Document[p127] matching the :visited[p765] pseudo-class to the resulting color.

When a body[p199] element has an alink[p1366] attribute, its value is expected to be parsed using the rules for parsing a legacy color value[p91], and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the 'color' property of any element in the Document[p127] matching the :active[p765] pseudo-class and either the :link[p765] pseudo-class or the :visited[p765] pseudo-class to the resulting color.

15.3.3 Flow content §[p1328]

```css
@namespace "http://www.w3.org/1999/xhtml";

address, blockquote, center, dialog, div, figure, figcaption, footer, form,
header, hr, legend, listing, main, p, plaintext, pre, search, xmp {
  display: block;
}

blockquote, figure, listing, p, plaintext, pre, xmp {
  margin-block-start: 1em; margin-block-end: 1em;
}

blockquote, figure { margin-inline-start: 40px; margin-inline-end: 40px; }

address { font-style: italic; }
listing, plaintext, pre, xmp {
  font-family: monospace; white-space: pre;
}

dialog:not([open]) { display: none; }
dialog {
  position: absolute;
  inset-inline-start: 0; inset-inline-end: 0;
  width: fit-content;
  height: fit-content;
  margin: auto;
  border: solid;
  padding: 1em;
  background-color: Canvas;
  color: CanvasText;
}
dialog:modal {
  position: fixed;
  overflow: auto;
  inset-block: 0;
```

```
  max-width: calc(100% - 6px - 2em);
  max-height: calc(100% - 6px - 2em);
}
dialog::backdrop {
  background: rgba(0,0,0,0.1);
}

[popover]:not(:popover-open):not(dialog[open]) {
  display:none;
}

dialog:popover-open {
  display:block;
}

[popover] {
  position: fixed;
  inset: 0;
  width: fit-content;
  height: fit-content;
  margin: auto;
  border: solid;
  padding: 0.25em;
  overflow: auto;
  color: CanvasText;
  background-color: Canvas;
}

:popover-open::backdrop {
  position: fixed;
  inset: 0;
  pointer-events: none !important;
  background-color: transparent;
}

slot {
  display: contents;
}
```

The following rules are also expected to apply, as presentational hints[p1326]:

```
@namespace "http://www.w3.org/1999/xhtml";

pre[wrap] { white-space: pre-wrap; }
```

In quirks mode, the following rules are also expected to apply:

```
@namespace "http://www.w3.org/1999/xhtml";

form { margin-block-end: 1em; }
```

The center[p1363] element, and the div[p251] element when it has an align[p1366] attribute whose value is an ASCII case-insensitive match for either the string "center" or the string "middle", are expected to center text within themselves, as if they had their 'text-align' property set to 'center' in a presentational hint[p1326], and to align descendants[p1326] to the center.

The div[p251] element, when it has an align[p1366] attribute whose value is an ASCII case-insensitive match for the string "left", is expected to left-align text within itself, as if it had its 'text-align' property set to 'left' in a presentational hint[p1326], and to align descendants[p1326] to the left.

The div[p251] element, when it has an align[p1366] attribute whose value is an ASCII case-insensitive match for the string "right", is

expected to right-align text within itself, as if it had its 'text-align' property set to 'right' in a presentational hint[p1326], and to align descendants[p1326] to the right.

The div[p251] element, when it has an align[p1366] attribute whose value is an ASCII case-insensitive match for the string "justify", is expected to full-justify text within itself, as if it had its 'text-align' property set to 'justify' in a presentational hint[p1326], and to align descendants[p1326] to the left.

15.3.4 Phrasing content §[p1330]

```
@namespace "http://www.w3.org/1999/xhtml";

cite, dfn, em, i, var { font-style: italic; }
b, strong { font-weight: bolder; }
code, kbd, samp, tt { font-family: monospace; }
big { font-size: larger; }
small { font-size: smaller; }

sub { vertical-align: sub; }
sup { vertical-align: super; }
sub, sup { line-height: normal; font-size: smaller; }

ruby { display: ruby; }
rt { display: ruby-text; }

:link { color: #0000EE; }
:visited { color: #551A8B; }
:link:active, :visited:active { color: #FF0000; }
:link, :visited { text-decoration: underline; cursor: pointer; }

:focus-visible { outline: auto; }

mark { background: yellow; color: black; } /* this color is just a suggestion and can be changed based
on implementation feedback */

abbr[title], acronym[title] { text-decoration: dotted underline; }
ins, u { text-decoration: underline; }
del, s, strike { text-decoration: line-through; }

q::before { content: open-quote; }
q::after { content: close-quote; }

br { display-outside: newline; } /* this also has bidi implications */
nobr { white-space: nowrap; }
wbr { display-outside: break-opportunity; } /* this also has bidi implications */
nobr wbr { white-space: normal; }
```

The following rules are also expected to apply, as presentational hints[p1326]:

```
@namespace "http://www.w3.org/1999/xhtml";

br[clear=left i] { clear: left; }
br[clear=right i] { clear: right; }
br[clear=all i], br[clear=both i] { clear: both; }
```

For the purposes of the CSS ruby model, runs of children of ruby[p265] elements that are not rt[p271] or rp[p272] elements are expected to be wrapped in anonymous boxes whose 'display' property has the value 'ruby-base'. [CSSRUBY][p1412]

When a particular part of a ruby has more than one annotation, the annotations should be distributed on both sides of the base text so as to minimize the stacking of ruby annotations on one side.

Note

When it becomes possible to do so, the preceding requirement will be updated to be expressed in terms of CSS ruby. (Currently, CSS ruby does not handle nested `ruby`[p265] elements or multiple sequential `rt`[p271] elements, which is how this semantic is expressed.)

User agents that do not support correct ruby rendering are expected to render parentheses around the text of `rt`[p271] elements in the absence of `rp`[p272] elements.

User agents are expected to support the 'clear' property on inline elements (in order to render `br`[p294] elements with `clear`[p1366] attributes) in the manner described in the non-normative note to this effect in *CSS*.

The initial value for the 'color' property is expected to be black. The initial value for the 'background-color' property is expected to be 'transparent'. The canvas's background is expected to be white.

When a `font`[p1363] element has a `color` attribute, its value is expected to be parsed using the rules for parsing a legacy color value[p91], and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the element's 'color' property to the resulting color.

When a `font`[p1363] element has a `face` attribute, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the element's 'font-family' property to the attribute's value.

When a `font`[p1363] element has a `size` attribute, the user agent is expected to use the following steps, known as the **rules for parsing a legacy font size**, to treat the attribute as a presentational hint[p1326] setting the element's 'font-size' property:

1. Let *input* be the attribute's value.
2. Let *position* be a pointer into *input*, initially pointing at the start of the string.
3. Skip ASCII whitespace within *input* given *position*.
4. If *position* is past the end of *input*, there is no presentational hint[p1326]. Return.
5. If the character at *position* is a U+002B PLUS SIGN character (+), then let *mode* be *relative-plus*, and advance *position* to the next character. Otherwise, if the character at *position* is a U+002D HYPHEN-MINUS character (-), then let *mode* be *relative-minus*, and advance *position* to the next character. Otherwise, let *mode* be *absolute*.
6. Collect a sequence of code points that are ASCII digits from *input* given *position*, and let the resulting sequence be *digits*.
7. If *digits* is the empty string, there is no presentational hint[p1326]. Return.
8. Interpret *digits* as a base-ten integer. Let *value* be the resulting number.
9. If *mode* is *relative-plus*, then increment *value* by 3. If *mode* is *relative-minus*, then let *value* be the result of subtracting *value* from 3.
10. If *value* is greater than 7, let it be 7.
11. If *value* is less than 1, let it be 1.
12. Set 'font-size' to the keyword corresponding to the value of *value* according to the following table:

value	'font-size' keyword
1	'x-small'
2	'small'
3	'medium'
4	'large'
5	'x-large'
6	'xx-large'
7	'xxx-large'

15.3.5 Bidirectional text §[p1332]

```
@namespace "http://www.w3.org/1999/xhtml";

[dir]:dir(ltr), bdi:dir(ltr), input[type=tel i]:dir(ltr) { direction: ltr; }
[dir]:dir(rtl), bdi:dir(rtl) { direction: rtl; }

address, blockquote, center, div, figure, figcaption, footer, form, header, hr,
legend, listing, main, p, plaintext, pre, summary, xmp, article, aside, h1, h2,
h3, h4, h5, h6, hgroup, nav, section, search, table, caption, colgroup, col,
thead, tbody, tfoot, tr, td, th, dir, dd, dl, dt, menu, ol, ul, li, bdi, output,
[dir=ltr i], [dir=rtl i], [dir=auto i] {
  unicode-bidi: isolate;
}

bdo, bdo[dir] { unicode-bidi: isolate-override; }

input[dir=auto i]:is([type=search i], [type=tel i], [type=url i],
[type=email i]), textarea[dir=auto i], pre[dir=auto i] {
  unicode-bidi: plaintext;
}
/* see prose for input elements whose type attribute is in the Text state */

/* the rules setting the 'content' property on br and wbr elements also has bidi implications */
```

When an input[p512] element's dir[p156] attribute is in the auto[p157] state and its type[p514] attribute is in the Text[p519] state, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the 'unicode-bidi' property to 'plaintext'.

Input fields (i.e. textarea[p570] elements, and input[p512] elements when their type[p514] attribute is in the Text[p519], Search[p519], Telephone[p519], URL[p520], or Email[p521] state) are expected to present an editing user interface with a directionality that matches the element's 'direction' property.

When the document's character encoding is ISO-8859-8, the following rules are additionally expected to apply, following those above: [ENCODING][p1413]

```
@namespace "http://www.w3.org/1999/xhtml";

address, blockquote, center, div, figure, figcaption, footer, form, header, hr,
legend, listing, main, p, plaintext, pre, summary, xmp, article, aside, h1, h2,
h3, h4, h5, h6, hgroup, nav, section, search, table, caption, colgroup, col,
thead, tbody, tfoot, tr, td, th, dir, dd, dl, dt, menu, ol, ul, li, [dir=ltr i],
[dir=rtl i], [dir=auto i], *|* {
  unicode-bidi: bidi-override;
}
input:not([type=submit i]):not([type=reset i]):not([type=button i]),
textarea {
  unicode-bidi: normal;
}
```

15.3.6 Sections and headings §[p1332]

```
@namespace "http://www.w3.org/1999/xhtml";

article, aside, h1, h2, h3, h4, h5, h6, hgroup, nav, section {
  display: block;
}

h1 { margin-block-start: 0.67em; margin-block-end: 0.67em; font-size: 2.00em; font-weight: bold; }
h2 { margin-block-start: 0.83em; margin-block-end: 0.83em; font-size: 1.50em; font-weight: bold; }
```

```
h3 { margin-block-start: 1.00em; margin-block-end: 1.00em; font-size: 1.17em; font-weight: bold; }
h4 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; font-weight: bold; }
h5 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; font-weight: bold; }
h6 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; font-weight: bold; }
```

In the following CSS block, *x* is shorthand for the following selector: `:is(article, aside, nav, section)`

```
@namespace "http://www.w3.org/1999/xhtml";

x h1 { margin-block-start: 0.83em; margin-block-end: 0.83em; font-size: 1.50em; }
x x h1 { margin-block-start: 1.00em; margin-block-end: 1.00em; font-size: 1.17em; }
x x x h1 { margin-block-start: 1.33em; margin-block-end: 1.33em; font-size: 1.00em; }
x x x x h1 { margin-block-start: 1.67em; margin-block-end: 1.67em; font-size: 0.83em; }
x x x x x h1 { margin-block-start: 2.33em; margin-block-end: 2.33em; font-size: 0.67em; }
```

Note

The shorthand is used to keep this block at least mildly readable.

15.3.7 Lists §[p13 33]

```
@namespace "http://www.w3.org/1999/xhtml";

dir, dd, dl, dt, menu, ol, ul { display: block; }
li { display: list-item; text-align: match-parent; }

dir, dl, menu, ol, ul { margin-block-start: 1em; margin-block-end: 1em; }

:is(dir, dl, menu, ol, ul) :is(dir, dl, menu, ol, ul) {
  margin-block-start: 0; margin-block-end: 0;
}

dd { margin-inline-start: 40px; }
dir, menu, ol, ul { padding-inline-start: 40px; }

ol, ul, menu { counter-reset: list-item; }
ol { list-style-type: decimal; }

dir, menu, ul {
  list-style-type: disc;
}
:is(dir, menu, ol, ul) :is(dir, menu, ul) {
  list-style-type: circle;
}
:is(dir, menu, ol, ul) :is(dir, menu, ol, ul) :is(dir, menu, ul) {
  list-style-type: square;
}
```

The following rules are also expected to apply, as presentational hints[p1326]:

```
@namespace "http://www.w3.org/1999/xhtml";

ol[type="1"], li[type="1"] { list-style-type: decimal; }
ol[type=a s], li[type=a s] { list-style-type: lower-alpha; }
ol[type=A s], li[type=A s] { list-style-type: upper-alpha; }
ol[type=i s], li[type=i s] { list-style-type: lower-roman; }
ol[type=I s], li[type=I s] { list-style-type: upper-roman; }
ul[type=none i], li[type=none i] { list-style-type: none; }
```

```
ul[type=disc i], li[type=disc i] { list-style-type: disc; }
ul[type=circle i], li[type=circle i] { list-style-type: circle; }
ul[type=square i], li[type=square i] { list-style-type: square; }
```

When rendering li[p236] elements, non-CSS user agents are expected to use the ordinal value[p237] of the li[p236] element to render the counter in the list item marker.

For CSS user agents, some aspects of rendering list items are defined by the *CSS Lists* specification. Additionally, the following attribute mappings are expected to apply: [CSSLISTS][p1412]

When an li[p236] element has a value[p236] attribute, and parsing that attribute's value using the rules for parsing integers[p74] doesn't generate an error, the user agent is expected to use the parsed value *value* as a presentational hint[p1326] for the 'counter-set' property of the form `list-item` *`value`*.

When an ol[p232] element has a start[p233] attribute or a reversed[p233] attribute, or both, the user agent is expected to use the following steps to treat the attributes as a presentational hint[p1326] for the 'counter-reset' property:

1. Let *value* be null.
2. If the element has a start[p233] attribute, then set *value* to the result of parsing the attribute's value using the rules for parsing integers[p74].
3. If the element has a reversed[p233] attribute, then:
    1. If *value* is an integer, then increment *value* by 1 and return `reversed(list-item)` *`value`*.
    2. Otherwise, return `reversed(list-item)`.

    Note
    Either the start[p233] attribute was absent, or parsing its value resulted in an error.
4. Otherwise:
    1. If *value* is an integer, then decrement *value* by 1 and return `list-item` *`value`*.
    2. Otherwise, there is no presentational hint[p1326].

15.3.8 Tables §[p1334]

```
@namespace "http://www.w3.org/1999/xhtml";

table { display: table; }
caption { display: table-caption; }
colgroup, colgroup[hidden] { display: table-column-group; }
col, col[hidden] { display: table-column; }
thead, thead[hidden] { display: table-header-group; }
tbody, tbody[hidden] { display: table-row-group; }
tfoot, tfoot[hidden] { display: table-footer-group; }
tr, tr[hidden] { display: table-row; }
td, th { display: table-cell; }

colgroup[hidden], col[hidden], thead[hidden], tbody[hidden],
tfoot[hidden], tr[hidden] {
  visibility: collapse;
}

table {
  box-sizing: border-box;
  border-spacing: 2px;
  border-collapse: separate;
  text-indent: initial;
```

```
}
td, th { padding: 1px; }
th { font-weight: bold; }

caption { text-align: center; }
thead, tbody, tfoot, table > tr { vertical-align: middle; }
tr, td, th { vertical-align: inherit; }

thead, tbody, tfoot, tr { border-color: inherit; }
table[rules=none i], table[rules=groups i], table[rules=rows i],
table[rules=cols i], table[rules=all i], table[frame=void i],
table[frame=above i], table[frame=below i], table[frame=hsides i],
table[frame=lhs i], table[frame=rhs i], table[frame=vsides i],
table[frame=box i], table[frame=border i],
table[rules=none i] > tr > td, table[rules=none i] > tr > th,
table[rules=groups i] > tr > td, table[rules=groups i] > tr > th,
table[rules=rows i] > tr > td, table[rules=rows i] > tr > th,
table[rules=cols i] > tr > td, table[rules=cols i] > tr > th,
table[rules=all i] > tr > td, table[rules=all i] > tr > th,
table[rules=none i] > thead > tr > td, table[rules=none i] > thead > tr > th,
table[rules=groups i] > thead > tr > td, table[rules=groups i] > thead > tr > th,
table[rules=rows i] > thead > tr > td, table[rules=rows i] > thead > tr > th,
table[rules=cols i] > thead > tr > td, table[rules=cols i] > thead > tr > th,
table[rules=all i] > thead > tr > td, table[rules=all i] > thead > tr > th,
table[rules=none i] > tbody > tr > td, table[rules=none i] > tbody > tr > th,
table[rules=groups i] > tbody > tr > td, table[rules=groups i] > tbody > tr > th,
table[rules=rows i] > tbody > tr > td, table[rules=rows i] > tbody > tr > th,
table[rules=cols i] > tbody > tr > td, table[rules=cols i] > tbody > tr > th,
table[rules=all i] > tbody > tr > td, table[rules=all i] > tbody > tr > th,
table[rules=none i] > tfoot > tr > td, table[rules=none i] > tfoot > tr > th,
table[rules=groups i] > tfoot > tr > td, table[rules=groups i] > tfoot > tr > th,
table[rules=rows i] > tfoot > tr > td, table[rules=rows i] > tfoot > tr > th,
table[rules=cols i] > tfoot > tr > td, table[rules=cols i] > tfoot > tr > th,
table[rules=all i] > tfoot > tr > td, table[rules=all i] > tfoot > tr > th {
  border-color: black;
}
```

The following rules are also expected to apply, as presentational hints[p1326]:

```
@namespace "http://www.w3.org/1999/xhtml";

table[align=left i] { float: left; }
table[align=right i] { float: right; }
table[align=center i] { margin-inline-start: auto; margin-inline-end: auto; }
thead[align=absmiddle i], tbody[align=absmiddle i], tfoot[align=absmiddle i],
tr[align=absmiddle i], td[align=absmiddle i], th[align=absmiddle i] {
  text-align: center;
}

caption[align=bottom i] { caption-side: bottom; }

  border-block-start-style: solid;
  border-block-end-width: 1px;
  border-block-end-style: solid;
}
```

In quirks mode, the following rules are also expected to apply:

```
@namespace "http://www.w3.org/1999/xhtml";

table {
  font-weight: initial;
  font-style: initial;
  font-variant: initial;
  font-size: initial;
  line-height: initial;
  white-space: initial;
  text-align: initial;
}
```

For the purposes of the CSS table model, the col[p479] element is expected to be treated as if it was present as many times as its span[p479] attribute specifies[p74].

For the purposes of the CSS table model, the colgroup[p478] element, if it contains no col[p479] element, is expected to be treated as if it had as many such children as its span[p479] attribute specifies[p74].

For the purposes of the CSS table model, the colspan[p488] and rowspan[p488] attributes on td[p484] and th[p486] elements are expected to

provide[p74] the *special knowledge* regarding cells spanning rows and columns.

In HTML documents, the following rules are also expected to apply:

```
CSS
@namespace "http://www.w3.org/1999/xhtml";

:is(table, thead, tbody, tfoot, tr) > form { display: none !important; }
```

The table[p469] element's cellspacing[p1367] attribute maps to the pixel length property[p1326] 'border-spacing' on the element.

The table[p469] element's cellpadding[p1367] attribute maps to the pixel length properties[p1326] 'padding-top', 'padding-right', 'padding-bottom', and 'padding-left' of any td[p484] and th[p486] elements that have corresponding cells[p489] in the table[p489] corresponding to the table[p469] element.

The table[p469] element's height[p1367] attribute maps to the dimension property[p1326] 'height' on the table[p469] element.

The table[p469] element's width[p1367] attribute maps to the dimension property (ignoring zero)[p1326] 'width' on the table[p469] element.

The col[p479] element's width[p1366] attribute maps to the dimension property[p1326] 'width' on the col[p479] element.

The thead[p481], tbody[p480], and tfoot[p482] elements' height[p1367] attribute maps to the dimension property[p1326] 'height' on the element.

The tr[p483] element's height[p1367] attribute maps to the dimension property[p1326] 'height' on the tr[p483] element.

The td[p484] and th[p486] elements' height[p1367] attributes map to the dimension property (ignoring zero)[p1326] 'height' on the element.

The td[p484] and th[p486] elements' width[p1367] attributes map to the dimension property (ignoring zero)[p1326] 'width' on the element.

The thead[p481], tbody[p480], tfoot[p482], tr[p483], td[p484], and th[p486] elements, when they have an `align` attribute whose value is an ASCII case-insensitive match for either the string "`center`" or the string "`middle`", are expected to center text within themselves, as if they had their 'text-align' property set to 'center' in a presentational hint[p1326], and to align descendants[p1326] to the center.

The thead[p481], tbody[p480], tfoot[p482], tr[p483], td[p484], and th[p486] elements, when they have an `align` attribute whose value is an ASCII case-insensitive match for the string "`left`", are expected to left-align text within themselves, as if they had their 'text-align' property set to 'left' in a presentational hint[p1326], and to align descendants[p1326] to the left.

The thead[p481], tbody[p480], tfoot[p482], tr[p483], td[p484], and th[p486] elements, when they have an `align` attribute whose value is an ASCII case-insensitive match for the string "`right`", are expected to right-align text within themselves, as if they had their 'text-align' property set to 'right' in a presentational hint[p1326], and to align descendants[p1326] to the right.

The thead[p481], tbody[p480], tfoot[p482], tr[p483], td[p484], and th[p486] elements, when they have an `align` attribute whose value is an ASCII case-insensitive match for the string "`justify`", are expected to full-justify text within themselves, as if they had their 'text-align' property set to 'justify' in a presentational hint[p1326], and to align descendants[p1326] to the left.

User agents are expected to have a rule in their user agent style sheet that matches th[p486] elements that have a parent node whose computed value for the 'text-align' property is its initial value, whose declaration block consists of just a single declaration that sets the 'text-align' property to the value 'center'.

When a table[p469], thead[p481], tbody[p480], tfoot[p482], tr[p483], td[p484], or th[p486] element has a background[p1367] attribute set to a non-empty value, the new value is expected to be parsed[p95] relative to the element's node document, and if this is successful, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the element's 'background-image' property to the resulting URL string[p95].

When a table[p469], thead[p481], tbody[p480], tfoot[p482], tr[p483], td[p484], or th[p486] element has a `bgcolor` attribute set, the new value is expected to be parsed using the rules for parsing a legacy color value[p91], and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the element's 'background-color' property to the resulting color.

When a table[p469] element has a bordercolor[p1367] attribute, its value is expected to be parsed using the rules for parsing a legacy color value[p91], and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the element's 'border-top-color', 'border-right-color', 'border-bottom-color', and 'border-left-color' properties to the resulting color.

The table[p469] element's border[p1367] attribute maps to the pixel length properties[p1326] 'border-top-width', 'border-right-width', 'border-bottom-width', 'border-left-width' on the element. If the attribute is present but parsing the attribute's value using the rules for parsing non-negative integers[p74] generates an error, a default value of 1px is expected to be used for that property instead.

Rules marked "**only if border is not equivalent to zero**" in the CSS block above is expected to only be applied if the border[p1367] attribute mentioned in the selectors for the rule is not only present but, when parsed using the rules for parsing non-negative integers[p74], is also found to have a value other than zero or to generate an error.

In quirks mode, a td[p484] element or a th[p486] element that has a nowrap[p1367] attribute but also has a width[p1367] attribute whose value, when parsed using the rules for parsing nonzero dimension values[p77], is found to be a length (not an error or a number classified as a percentage), is expected to have a presentational hint[p1326] setting the element's 'white-space' property to 'normal', overriding the rule in the CSS block above that sets it to 'nowrap'.

15.3.9 Margin collapsing quirks §[p1339]

A node is **substantial** if it is a text node that is not inter-element whitespace[p144], or if it is an element node.

A node is **blank** if it is an element that contains no substantial[p1339] nodes.

The **elements with default margins** are the following elements: blockquote[p229], dir[p1362], dl[p238], h1[p211], h2[p211], h3[p211], h4[p211], h5[p211], h6[p211], listing[p1362], menu[p235], ol[p232], p[p223], plaintext[p1362], pre[p228], ul[p234], xmp[p1363]

In quirks mode, any element with default margins[p1339] that is the child of a body[p199], td[p484], or th[p486] element and has no substantial[p1339] previous siblings is expected to have a user-agent level style sheet rule that sets its 'margin-block-start' property to zero.

In quirks mode, any element with default margins[p1339] that is the child of a body[p199], td[p484], or th[p486] element, has no substantial[p1339] previous siblings, and is blank[p1339], is expected to have a user-agent level style sheet rule that sets its 'margin-block-end' property to zero also.

In quirks mode, any element with default margins[p1339] that is the child of a td[p484] or th[p486] element, has no substantial[p1339] following siblings, and is blank[p1339], is expected to have a user-agent level style sheet rule that sets its 'margin-block-start' property to zero.

In quirks mode, any p[p223] element that is the child of a td[p484] or th[p486] element and has no substantial[p1339] following siblings, is expected to have a user-agent level style sheet rule that sets its 'margin-block-end' property to zero.

15.3.10 Form controls §[p1339]

```
CSS
@namespace "http://www.w3.org/1999/xhtml";

input, select, button, textarea {
  letter-spacing: initial;
  word-spacing: initial;
  line-height: initial;
  text-transform: initial;
  text-indent: initial;
  text-shadow: initial;
  appearance: auto;
}

input, select, textarea {
  text-align: initial;
}

input:is([type=reset i], [type=button i], [type=submit i]), button {
  text-align: center;
}
```

```
input, button {
  display: inline-block;
}

input[type=hidden i], input[type=file i], input[type=image i] {
  appearance: none;
}

input:is([type=radio i], [type=checkbox i], [type=reset i], [type=button i],
[type=submit i], [type=color i], [type=search i]), select, button {
  box-sizing: border-box;
}

textarea { white-space: pre-wrap; }
```

In quirks mode, the following rules are also expected to apply:

```
@namespace "http://www.w3.org/1999/xhtml";

input:not([type=image i]), textarea { box-sizing: border-box; }
```

Each kind of form control is also described in the Widgets[p1347] section, which describes the look and feel of the control.

For input[p512] elements where the type[p514] attribute is not in the Hidden[p518] state or the Image Button[p538] state, and that are being rendered[p1325], are expected to act as follows:

- The inner display type is always 'flow-root'.
- The 'overflow' property is ignored, and always behaves as 'visible' for the purpose of interaction with other CSS features (in particular, the 'vertical-align' property), but still clips any overflow at the border edge, and no scrolling mechanism is displayed.

15.3.11 The hr[p226] element §[p1340]

```
@namespace "http://www.w3.org/1999/xhtml";

hr {
  color: gray;
  border-style: inset;
  border-width: 1px;
  margin-block-start: 0.5em;
  margin-inline-end: auto;
  margin-block-end: 0.5em;
  margin-inline-start: auto;
  overflow: hidden;
}
```

The following rules are also expected to apply, as presentational hints[p1326]:

```
@namespace "http://www.w3.org/1999/xhtml";

hr[align=left i] { margin-left: 0; margin-right: auto; }
hr[align=right i] { margin-left: auto; margin-right: 0; }
hr[align=center i] { margin-left: auto; margin-right: auto; }
hr[color], hr[noshade] { border-style: solid; }
```

If an hr[p226] element has either a color[p1366] attribute or a noshade[p1366] attribute, and furthermore also has a size[p1366] attribute, and parsing that attribute's value using the rules for parsing non-negative integers[p74] doesn't generate an error, then the user agent is

expected to use the parsed value divided by two as a pixel length for presentational hints[p1326] for the properties 'border-top-width', 'border-right-width', 'border-bottom-width', and 'border-left-width' on the element.

Otherwise, if an hr[p226] element has neither a color[p1366] attribute nor a noshade[p1366] attribute, but does have a size[p1366] attribute, and parsing that attribute's value using the rules for parsing non-negative integers[p74] doesn't generate an error, then: if the parsed value is one, then the user agent is expected to use the attribute as a presentational hint[p1326] setting the element's 'border-bottom-width' to 0; otherwise, if the parsed value is greater than one, then the user agent is expected to use the parsed value minus two as a pixel length for presentational hints[p1326] for the 'height' property on the element.

The width[p1366] attribute on an hr[p226] element maps to the dimension property[p1326] 'width' on the element.

When an hr[p226] element has a color[p1366] attribute, its value is expected to be parsed using the rules for parsing a legacy color value[p91], and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the element's 'color' property to the resulting color.

15.3.12 The fieldset[p584] and legend[p586] elements §[p1341]

CSS
```
@namespace "http://www.w3.org/1999/xhtml";

fieldset {
  display: block;
  margin-inline-start: 2px;
  margin-inline-end: 2px;
  border: groove 2px ThreeDFace;
  padding-block-start: 0.35em;
  padding-inline-end: 0.75em;
  padding-block-end: 0.625em;
  padding-inline-start: 0.75em;
  min-inline-size: min-content;
}

legend {
  padding-inline-start: 2px; padding-inline-end: 2px;
}

legend[align=left i] {
  justify-self: left;
}

legend[align=center i] {
  justify-self: center;
}

legend[align=right i] {
  justify-self: right;
}
```

The fieldset[p584] element, when it generates a CSS box, is expected to act as follows:

- The element is expected to establish a new block formatting context.
- The 'display' property is expected to act as follows:
  - If the computed value of 'display' is a value such that the outer display type is 'inline', then behave as 'inline-block'.
  - Otherwise, behave as 'flow-root'.

Note
This does not change the computed value.

- If the element's box has a child box that matches the conditions in the list below, then the first such child box is the 'fieldset' element's **rendered legend**:
    - The child is a legend[p586] element.
    - The child's used value of 'float' is 'none'.
    - The child's used value of 'position' is not 'absolute' or 'fixed'.
- If the element has a rendered legend[p1342], then the border is expected to not be painted behind the rectangle defined as follows, using the writing mode of the fieldset:
    1. The block-start edge of the rectangle is the smaller of the block-start edge of the rendered legend[p1342]'s margin rectangle at its static position (ignoring transforms), and the block-start outer edge of the fieldset[p584]'s border.
    2. The block-end edge of the rectangle is the larger of the block-end edge of the rendered legend[p1342]'s margin rectangle at its static position (ignoring transforms), and the block-end outer edge of the fieldset[p584]'s border.
    3. The inline-start edge of the rectangle is the smaller of the inline-start edge of the rendered legend[p1342]'s border rectangle at its static position (ignoring transforms), and the inline-start outer edge of the fieldset[p584]'s border.
    4. The inline-end edge of the rectangle is the larger of the inline-end edge of the rendered legend[p1342]'s border rectangle at its static position (ignoring transforms), and the inline-end outer edge of the fieldset[p584]'s border.
- The space allocated for the element's border on the block-start side is expected to be the element's 'border-block-start-width' or the rendered legend[p1342]'s margin box size in the fieldset[p584]'s block-flow direction, whichever is greater.
- For the purpose of calculating the used 'block-size', if the computed 'block-size' is not 'auto', the space allocated for the rendered legend[p1342]'s margin box that spills out past the border, if any, is expected to be subtracted from the 'block-size'. If the content box's block-size would be negative, then let the content box's block-size be zero instead.
- If the element has a rendered legend[p1342], then that element is expected to be the first child box.
- The anonymous fieldset content box[p1343] is expected to appear after the rendered legend[p1342] and is expected to contain the content (including the '::before' and '::after' pseudo-elements) of the fieldset[p584] element except for the rendered legend[p1342], if there is one.
- The used value of the 'padding-top', 'padding-right', 'padding-bottom', and 'padding-left' properties are expected to be zero.
- For the purpose of calculating the min-content inline size, use the greater of the min-content inline size of the rendered legend[p1342] and the min-content inline size of the anonymous fieldset content box[p1343].
- For the purpose of calculating the max-content inline size, use the greater of the max-content inline size of the rendered legend[p1342] and the max-content inline size of the anonymous fieldset content box[p1343].

A fieldset[p584] element's rendered legend[p1342], if any, is expected to act as follows:

- The element is expected to establish a new formatting context for its contents. The type of this formatting context is determined by its 'display' value, as usual.
- The 'display' property is expected to behave as if its computed value was blockified.

  Note

  This does not change the computed value.

- If the computed value of 'inline-size' is 'auto', then the used value is the fit-content inline size.
- The element is expected to be positioned in the inline direction as is normal for blocks (e.g., taking into account margins and the 'justify-self' property).
- The element's box is expected to be constrained in the inline direction by the inline content size of the fieldset[p584] as if it had used its computed inline padding.

  Example

  For example, if the fieldset[p584] has a specified padding of 50px, then the rendered legend[p1342] will be positioned 50px in from the fieldset[p584]'s border. The padding will further apply to the anonymous fieldset content box[p1343] instead of the fieldset[p584] element itself.

- The element is expected to be positioned in the block-flow direction such that its border box is centered over the border on the block-start side of the fieldset[p584] element.

A `fieldset`[p584] element's **anonymous fieldset content box** is expected to act as follows:

- The 'display' property is expected to act as follows:
  - If the computed value of 'display' on the `fieldset`[p584] element is 'grid' or 'inline-grid', then set the used value to 'grid'.
  - If the computed value of 'display' on the `fieldset`[p584] element is 'flex' or 'inline-flex', then set the used value to 'flex'.
  - Otherwise, set the used value to 'flow-root'.
- The following properties are expected to inherit from the `fieldset`[p584] element:
  - 'align-content'
  - 'align-items'
  - 'border-radius'
  - 'column-count'
  - 'column-fill'
  - 'column-gap'
  - 'column-rule'
  - 'column-width'
  - 'flex-direction'
  - 'flex-wrap'
  - 'grid-auto-columns'
  - 'grid-auto-flow'
  - 'grid-auto-rows'
  - 'grid-column-gap'
  - 'grid-row-gap'
  - 'grid-template-areas'
  - 'grid-template-columns'
  - 'grid-template-rows'
  - 'justify-content'
  - 'justify-items'
  - 'overflow'
  - 'padding-bottom'
  - 'padding-left'
  - 'padding-right'
  - 'padding-top'
  - 'text-overflow'
  - 'unicode-bidi'
- The 'block-size' property is expected to be set to '100%'.
- For the purpose of calculating percentage padding, act as if the padding was calculated for the `fieldset`[p584] element.

Note

The legend is rendered over the top border, and the top border area reserves vertical space for the legend. The fieldset's top margin starts at the top margin edge of the legend. The legend's horizontal margins, or the 'justify-self' property, gives its horizontal position. The anonymous fieldset content box[p1343] *appears below the legend.*

15.4 Replaced elements §[p1344]

Note

The following elements can be replaced elements: audio[p402], canvas[p661], embed[p391], iframe[p383], img[p338], input[p512], object[p394], and video[p398].

15.4.1 Embedded content §[p1344]

The embed[p391], iframe[p383], and video[p398] elements are expected to be treated as replaced elements.

A canvas[p661] element that represents[p138] embedded content[p147] is expected to be treated as a replaced element; the contents of such elements are the element's bitmap, if any, or else a transparent black bitmap with the same natural dimensions as the element. Other canvas[p661] elements are expected to be treated as ordinary elements in the rendering model.

An object[p394] element that represents[p138] an image, plugin, or its content navigable[p955] is expected to be treated as a replaced element. Other object[p394] elements are expected to be treated as ordinary elements in the rendering model.

The audio[p402] element, when it is exposing a user interface[p455], is expected to be treated as a replaced element about one line high, as wide as is necessary to expose the user agent's user interface features. When an audio[p402] element is not exposing a user interface[p455], the user agent is expected to force its 'display' property to compute to 'none', irrespective of CSS rules.

Whether a video[p398] element is exposing a user interface[p455] is not expected to affect the size of the rendering; controls are expected to be overlaid above the page content without causing any layout changes, and are expected to disappear when the user does not need them.

When a video[p398] element represents a poster frame or frame of video, the poster frame or frame of video is expected to be rendered at the largest size that maintains the aspect ratio of that poster frame or frame of video without being taller or wider than the video[p398] element itself, and is expected to be centered in the video[p398] element.

Any subtitles or captions are expected to be overlaid directly on top of their video[p398] element, as defined by the relevant rendering rules; for WebVTT, those are the rules for updating the display of WebVTT text tracks. [WEBVTT][p1418]

When the user agent starts exposing a user interface[p455] for a video[p398] element, the user agent should run the rules for updating the text track rendering[p442] of each of the text tracks[p441] in the video[p398] element's list of text tracks[p441] that are showing[p442] and whose text track kind[p441] is one of subtitles[p441] or captions[p441] (e.g., for text tracks[p441] based on WebVTT, the rules for updating the display of WebVTT text tracks). [WEBVTT][p1418]

Note

Resizing video[p398] and canvas[p661] elements does not interrupt video playback or clear the canvas.

The following CSS rules are expected to apply:

```
CSS
@namespace "http://www.w3.org/1999/xhtml";

iframe { border: 2px inset; }
video { object-fit: contain; }
```

15.4.2 Images §[p1344]

User agents are expected to render img[p338] elements and input[p512] elements whose type[p514] attributes are in the Image Button[p538] state, according to the first applicable rules from the following list:

↪ **If the element represents[p138] an image**

The user agent is expected to treat the element as a replaced element and render the image according to the rules for doing so defined in CSS.

↪ **If the element does not represent[p138] an image and either:**

- **the user agent has reason to believe that the image will become *available*[p356] and be rendered in due course, or**
- **the element has no `alt` attribute, or**
- **the `Document`[p127] is in quirks mode, and the element already has natural dimensions (e.g., from the dimension attributes[p468] or CSS rules)**

The user agent is expected to treat the element as a replaced element whose content is the text that the element represents, if any, optionally alongside an icon indicating that the image is being obtained (if applicable). For `input`[p512] elements, the element is expected to appear button-like to indicate that the element is a button[p505].

↪ **If the element is an `img`[p338] element that represents[p138] some text and the user agent does not expect this to change**

The user agent is expected to treat the element as a non-replaced phrasing element whose content is the text, optionally with an icon indicating that an image is missing, so that the user can request the image be displayed or investigate why it is not rendering. In non-graphical contexts, such an icon should be omitted.

↪ **If the element is an `img`[p338] element that represents[p138] nothing and the user agent does not expect this to change**

The user agent is expected to treat the element as a replaced element whose natural dimensions are 0. (In the absence of further styles, this will cause the element to essentially not be rendered.)

↪ **If the element is an `input`[p512] element that does not represent[p138] an image and the user agent does not expect this to change**

The user agent is expected to treat the element as a replaced element consisting of a button whose content is the element's alternative text. The natural dimensions of the button are expected to be about one line in height and whatever width is necessary to render the text on one line.

The icons mentioned above are expected to be relatively small so as not to disrupt most text but be easily clickable. In a visual environment, for instance, icons could be 16 pixels by 16 pixels square, or 1em by 1em if the images are scalable. In an audio environment, the icon could be a short bleep. The icons are intended to indicate to the user that they can be used to get to whatever options the UA provides for images, and, where appropriate, are expected to provide access to the context menu that would have come up if the user interacted with the actual image.

All animated images with the same absolute URL and the same image data are expected to be rendered synchronized to the same timeline as a group, with the timeline starting at the time of the least recent addition to the group.

Note

In other words, when a second image with the same absolute URL and animated image data is inserted into a document, it jumps to the point in the animation cycle that is currently being displayed by the first image.

When a user agent is to **restart the animation** for an `img`[p338] element showing an animated image, all animated images with the same absolute URL and the same image data in that `img`[p338] element's node document are expected to restart their animation from the beginning.

The following CSS rules are expected to apply when the `Document`[p127] is in quirks mode:

```
CSS
@namespace "http://www.w3.org/1999/xhtml";

img[align=left i] { margin-right: 3px; }
img[align=right i] { margin-left: 3px; }
```

15.4.3 Attributes for embedded content and images §[p1345]

The following CSS rules are expected to apply as presentational hints[p1326]:

```
CSS
@namespace "http://www.w3.org/1999/xhtml";

iframe[frameborder='0'], iframe[frameborder=no i] { border: none; }

embed[align=left i], iframe[align=left i], img[align=left i],
```

```
input[type=image i][align=left i], object[align=left i] {
  float: left;
}

embed[align=right i], iframe[align=right i], img[align=right i],
input[type=image i][align=right i], object[align=right i] {
  float: right;
}

embed[align=top i], iframe[align=top i], img[align=top i],
input[type=image i][align=top i], object[align=top i] {
  vertical-align: top;
}

embed[align=baseline i], iframe[align=baseline i], img[align=baseline i],
input[type=image i][align=baseline i], object[align=baseline i] {
  vertical-align: baseline;
}

embed[align=texttop i], iframe[align=texttop i], img[align=texttop i],
input[type=image i][align=texttop i], object[align=texttop i] {
  vertical-align: text-top;
}

embed[align=absmiddle i], iframe[align=absmiddle i], img[align=absmiddle i],
input[type=image i][align=absmiddle i], object[align=absmiddle i],
embed[align=abscenter i], iframe[align=abscenter i], img[align=abscenter i],
input[type=image i][align=abscenter i], object[align=abscenter i] {
  vertical-align: middle;
}

embed[align=bottom i], iframe[align=bottom i], img[align=bottom i],
input[type=image i][align=bottom i], object[align=bottom i] {
  vertical-align: bottom;
}
```

When an embed[p391], iframe[p383], img[p338], or object[p394] element, or an input[p512] element whose type[p514] attribute is in the Image Button[p538] state, has an `align` attribute whose value is an ASCII case-insensitive match for the string "`center`" or the string "`middle`", the user agent is expected to act as if the element's 'vertical-align' property was set to a value that aligns the vertical middle of the element with the parent element's baseline.

The `hspace` attribute of embed[p391], img[p338], or object[p394] elements, and input[p512] elements with a type[p514] attribute in the Image Button[p538] state, maps to the dimension properties[p1326] 'margin-left' and 'margin-right' on the element.

The `vspace` attribute of embed[p391], img[p338], or object[p394] elements, and input[p512] elements with a type[p514] attribute in the Image Button[p538] state, maps to the dimension properties[p1326] 'margin-top' and 'margin-bottom' on the element.

When an img[p338] element, object[p394] element, or input[p512] element with a type[p514] attribute in the Image Button[p538] state has a `border` attribute whose value, when parsed using the rules for parsing non-negative integers[p74], is found to be a number greater than zero, the user agent is expected to use the parsed value for eight presentational hints[p1326]: four setting the parsed value as a pixel length for the element's 'border-top-width', 'border-right-width', 'border-bottom-width', and 'border-left-width' properties, and four setting the element's 'border-top-style', 'border-right-style', 'border-bottom-style', and 'border-left-style' properties to the value 'solid'.

The width[p468] and height[p468] attributes on an img[p338] element's dimension attribute source[p339] map to the dimension properties[p1326] 'width' and 'height' on the img[p338] element respectively. They similarly map to the aspect-ratio property (using dimension rules)[p1326] of the img[p338] element.

The width[p468] and height[p468] attributes on embed[p391], iframe[p383], object[p394], and video[p398] elements, and input[p512] elements with a type[p514] attribute in the Image Button[p538] state and that either represents an image or that the user expects will eventually represent an image, map to the dimension properties[p1326] 'width' and 'height' on the element respectively.

The width[p468] and height[p468] attributes map to the aspect-ratio property (using dimension rules)[p1326] on img[p338] and video[p398] elements, and input[p512] elements with a type[p514] attribute in the Image Button[p538] state.

The width[p662] and height[p662] attributes map to the aspect-ratio property[p1326] on canvas[p661] elements.

15.4.4 Image maps §[p1347]

Shapes on an image map[p464] are expected to act, for the purpose of the CSS cascade, as elements independent of the original area[p463] element that happen to match the same style rules but inherit from the img[p338] or object[p394] element.

For the purposes of the rendering, only the 'cursor' property is expected to have any effect on the shape.

Example

Thus, for example, if an area[p463] element has a style[p159] attribute that sets the 'cursor' property to 'help', then when the user designates that shape, the cursor would change to a Help cursor.

Example

Similarly, if an area[p463] element had a CSS rule that set its 'cursor' property to 'inherit' (or if no rule setting the 'cursor' property matched the element at all), the shape's cursor would be inherited from the img[p338] or object[p394] element of the image map[p464], not from the parent of the area[p463] element.

15.5 Widgets §[p1347]

15.5.1 Native appearance §[p1347]

The *CSS Basic User Interface* specification calls elements that can have a native appearance widgets, and defines whether to use that native appearance depending on the 'appearance' property. That logic, in turn, depends on whether on whether each the element is classified as a devolvable widget or non-devolvable widget. This section defines which elements match these concepts for HTML, what their native appearance is, and any particularity of their devolved state or primitive appearance. [CSSUI][p1412]

The following elements can have a native appearance for the purpose of the CSS 'appearance' property.

- button[p556]
- input[p512]
- meter[p579]
- progress[p577]
- select[p559]
- textarea[p570]

15.5.2 Button layout §[p1347]

When an element uses button layout[p1347], it is a devolvable widget, and it's native appearance is that of a button.

Button layout is as follows:

- If the element is a button[p556] element, then the 'display' property is expected to act as follows:
  - If the computed value of 'display' is 'inline-grid', 'grid', 'inline-flex', or 'flex', then behave as the computed value.
  - Otherwise, if the computed value of 'display' is a value such that the outer display type is 'inline', then behave as 'inline-block'.
  - Otherwise, behave as 'flow-root'.
- The element is expected to establish a new formatting context for its contents. The type of this formatting context is determined by its 'display' value, as usual.
- If the element is absolutely-positioned, then for the purpose of the CSS visual formatting model, act as if the element is a replaced element. [CSS][p1411]
- If the computed value of 'inline-size' is 'auto', then the used value is the fit-content inline size.

- For the purpose of the 'normal' keyword of the 'align-self' property, act as if the element is a replaced element.
- If the element is an input[p512] element, or if it is a button[p556] element and its computed value for 'display' is not 'inline-grid', 'grid', 'inline-flex', or 'flex', then the element's box has a child **anonymous button content box** with the following behaviors:
  - The box is a block-level block container that establishes a new block formatting context (i.e., 'display' is 'flow-root').
  - If the box does not overflow in the horizontal axis, then it is centered horizontally.
  - If the box does not overflow in the vertical axis, then it is centered vertically.

  Otherwise, there is no anonymous button content box[p1348].

Need to define the expected primitive appearance.

15.5.3 The button[p556] element §[p13 48]

The button[p556] element, when it generates a CSS box, is expected to depict a button and to use button layout[p1347] whose anonymous button content box[p1348]'s contents (if there is an anonymous button content box[p1348]) are the child boxes the element's box would otherwise have.

15.5.4 The details[p627] and summary[p630] elements §[p13 48]

CSS
```
@namespace "http://www.w3.org/1999/xhtml";

details > summary:first-of-type {
  display: list-item;
  counter-increment: list-item 0;
  list-style: disclosure-closed inside;
}
details[open] > summary:first-of-type {
  list-style-type: disclosure-open;
}
```

The details[p627] element is expected to render as a block box. The element is also expected to have an internal shadow tree with two slots. The first slot is expected to take the details[p627] element's first summary[p630] element child, if any. The second slot is expected to take the details[p627] element's remaining descendants, if any.

The details[p627] element's first summary[p630] element child, if any, is expected to allow the user to request the details be shown or hidden.

The details[p627] element's second slot is expected to have its style[p159] attribute set to "`display: block; content-visibility: hidden;`" when the details[p627] element does not have an open[p627] attribute. When it does have the open[p627] attribute, the style[p159] attribute is expected to be removed from the second slot.

Note

Because the slots are hidden inside a shadow tree, this style[p159] *attribute is not directly visible to author code. Its impacts, however, are visible. Notably, the choice of* `content-visibility: hidden` *instead of, e.g.,* `display: none`*, impacts the results of various APIs that query layout information.*

15.5.5 The input[p512] element as a text entry widget §[p13 48]

An input[p512] element whose type[p514] attribute is in the Text[p519], Telephone[p519], URL[p520], or Email[p521] state, is a devolvable widget. Its expected native appearance is to render as an 'inline-block' box depicting a one-line text control.

An input[p512] element whose type[p514] attribute is in the Search[p519] state is a devolvable widget. Its expected native appearance is to render as an 'inline-block' box depicting a one-line text control. If the computed value of the element's 'appearance' property is not 'textfield', it may have a distinct style indicating that it is a search field.

An input[p512] element whose type[p514] attribute is in the Password[p523] state is a devolvable widget. Its expected native appearance is to render as an 'inline-block' box depicting a one-line text control that obscures data entry.

For input[p512] elements whose type[p514] attribute is in one of the above states, the used value of the 'line-height' property must be a length value that is no smaller than what the used value would be for 'line-height: normal'.

Note

The used value will not be the actual keyword 'normal'. Also, this rule does not affect the computed value.

If these text controls provide a text selection, then, when the user changes the current selection, the user agent is expected to queue an element task[p1073] on the user interaction task source[p1080] given the input[p512] element to fire an event named select[p1407] at the element, with the bubbles attribute initialized to true.

If an input[p512] element whose type[p514] attribute is in one of the above states has a size[p542] attribute, and parsing that attribute's value using the rules for parsing non-negative integers[p74] doesn't generate an error, then the user agent is expected to use the attribute as a presentational hint[p1326] for the 'width' property on the element, with the value obtained from applying the converting a character width to pixels[p1349] algorithm to the value of the attribute.

If an input[p512] element whose type[p514] attribute is in one of the above states does *not* have a size[p542] attribute, then the user agent is expected to act as if it had a user-agent-level style sheet rule setting the 'width' property on the element to the value obtained from applying the converting a character width to pixels[p1349] algorithm to the number 20.

The **converting a character width to pixels** algorithm returns (*size*-1)×*avg* + *max*, where *size* is the character width to convert, *avg* is the average character width of the primary font for the element for which the algorithm is being run, in pixels, and *max* is the maximum character width of that same font, also in pixels. (The element's 'letter-spacing' property does not affect the result.)

These text controls are expected to be scroll containers and support scrolling in the inline axis, but not the block axis.

Need to detail the expected native appearance and primitive appearance.

15.5.6 The input[p512] element as domain-specific widgets §[p1349]

An input[p512] element whose type[p514] attribute is in the Date[p523] state is a devolvable widget expected to render as an 'inline-block' box depicting a date control.

An input[p512] element whose type[p514] attribute is in the Month[p524] state is a devolvable widget expected to render as an 'inline-block' box depicting a month control.

An input[p512] element whose type[p514] attribute is in the Week[p525] state is a devolvable widget expected to render as an 'inline-block' box depicting a week control.

An input[p512] element whose type[p514] attribute is in the Time[p526] state is a devolvable widget expected to render as an 'inline-block' box depicting a time control.

An input[p512] element whose type[p514] attribute is in the Local Date and Time[p527] state is a devolvable widget expected to render as an 'inline-block' box depicting a local date and time control.

An input[p512] element whose type[p514] attribute is in the Number[p528] state is a devolvable widget expected to render as an 'inline-block' box depicting a number control.

These controls are all expected to be about one line high, and about as wide as necessary to show the widest possible value.

Need to detail the expected native appearance and primitive appearance.

15.5.7 The input[p512] element as a range control §[p1350]

An input[p512] element whose type[p514] attribute is in the Range[p530] state is a non-devolvable widget. Its expected native appearance is to render as an 'inline-block' box depicting a slider control.

When the control is wider than it is tall (or square), the control is expected to be a horizontal slider, with the lowest value on the right if the 'direction' property on this element has a computed value of 'rtl', and on the left otherwise. When the control is taller than it is wide, it is expected to be a vertical slider, with the lowest value on the bottom.

Predefined suggested values (provided by the list[p548] attribute) are expected to be shown as tick marks on the slider, which the slider can snap to.

User agents are expected to use the used value of the 'direction' property on the element to determine the direction in which the slider operates. Typically, a left-to-right ('ltr') horizontal control would have the lowest value on the left and the highest value on the right, and vice versa.

Need to detail the expected primitive appearance.

15.5.8 The input[p512] element as a color well §[p1350]

An input[p512] element whose type[p514] attribute is in the Color[p532] state is expected to depict a color well, which, when activated, provides the user with a color picker (e.g. a color wheel or color palette) from which the color can be changed. The element, when it generates a CSS box, is expected to use button layout[p1347], that has no child boxes of the anonymous button content box[p1348]. The anonymous button content box[p1348] is expected to have a presentational hint[p1326] setting the 'background-color' property to the element's value[p587].

Predefined suggested values (provided by the list[p548] attribute) are expected to be shown in the color picker interface, not on the color well itself.

Need to detail the expected native appearance and primitive appearance.

15.5.9 The input[p512] element as a checkbox and radio button widgets §[p1350]

An input[p512] element whose type[p514] attribute is in the Checkbox[p533] state is a non-devolvable widget expected to render as an 'inline-block' box containing a single checkbox control, with no label.

Need to detail the expected native appearance and primitive appearance.

An input[p512] element whose type[p514] attribute is in the Radio Button[p534] state is a non-devolvable widget expected to render as an 'inline-block' box containing a single radio button control, with no label.

Need to detail the expected native appearance and primitive appearance.

15.5.10 The input[p512] element as a file upload control §[p1350]

An input[p512] element whose type[p514] attribute is in the File Upload[p535] state, when it generates a CSS box, is expected to render as an 'inline-block' box containing a span of text giving the filename(s) of the selected files[p535], if any, followed by a button that, when activated, provides the user with a file picker from which the selection can be changed. The button is expected to use button layout[p1347] and match the '::file-selector-button' pseudo-element. The contents of its anonymous button content box[p1348] are expected to be implementation-defined (and possibly locale-specific) text, for example "Choose file".

15.5.11 The input[p512] element as a button §[p1351]

An input[p512] element whose type[p514] attribute is in the Submit Button[p537], Reset Button[p540], or Button[p540] state, when it generates a CSS box, is expected to depict a button and use button layout[p1347] and the contents of the anonymous button content box[p1348] are expected to be the text of the element's value[p516] attribute, if any, or text derived from the element's type[p514] attribute in an implementation-defined (and probably locale-specific) fashion, if not.

15.5.12 The marquee[p1367] element §[p1351]

```
CSS
@namespace "http://www.w3.org/1999/xhtml";

marquee {
  display: inline-block;
  text-align: initial;
}
```

The marquee[p1367] element, while turned on[p1368], is expected to render in an animated fashion according to its attributes as follows:

If the element's behavior[p1368] attribute is in the scroll[p1368] state

Slide the contents of the element in the direction described by the direction[p1368] attribute as defined below, such that it begins off the start side of the marquee[p1367], and ends flush with the inner end side.

Example

For example, if the direction[p1368] attribute is left[p1368] (the default), then the contents would start such that their left edge are off the side of the right edge of the marquee[p1367]'s content area, and the contents would then slide up to the point where the left edge of the contents are flush with the left inner edge of the marquee[p1367]'s content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index[p1369]. If the element is still turned on[p1368] after this, then the user agent is expected to restart the animation.

If the element's behavior[p1368] attribute is in the slide[p1368] state

Slide the contents of the element in the direction described by the direction[p1368] attribute as defined below, such that it begins off the start side of the marquee[p1367], and ends off the end side of the marquee[p1367].

Example

For example, if the direction[p1368] attribute is left[p1368] (the default), then the contents would start such that their left edge are off the side of the right edge of the marquee[p1367]'s content area, and the contents would then slide up to the point where the *right* edge of the contents are flush with the left inner edge of the marquee[p1367]'s content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index[p1369]. If the element is still turned on[p1368] after this, then the user agent is expected to restart the animation.

If the element's behavior[p1368] attribute is in the alternate[p1368] state

When the marquee current loop index[p1369] is even (or zero), slide the contents of the element in the direction described by the direction[p1368] attribute as defined below, such that it begins flush with the start side of the marquee[p1367], and ends flush with the end side of the marquee[p1367].

When the marquee current loop index[p1369] is odd, slide the contents of the element in the opposite direction than that described by the direction[p1368] attribute as defined below, such that it begins flush with the end side of the marquee[p1367], and ends flush with the start side of the marquee[p1367].

Example

For example, if the direction[p1368] attribute is left[p1368] (the default), then the contents would with their right edge flush with the right inner edge of the marquee[p1367]'s content area, and the contents would then slide up to the point where the *left* edge of the contents are flush with the left inner edge of the marquee[p1367]'s content area.

Once the animation has ended, the user agent is expected to increment the marquee current loop index[p1369]. If the element is still

turned on[p1368] after this, then the user agent is expected to continue the animation.

The direction[p1368] attribute has the meanings described in the following table:

direction[p1368] attribute state	Direction of animation	Start edge	End edge	Opposite direction
left[p1368]	← Right to left	Right	Left	→ Left to Right
right[p1368]	→ Left to Right	Left	Right	← Right to left
up[p1368]	↑ Up (Bottom to Top)	Bottom	Top	↓ Down (Top to Bottom)
down[p1368]	↓ Down (Top to Bottom)	Top	Bottom	↑ Up (Bottom to Top)

In any case, the animation should proceed such that there is a delay given by the marquee scroll interval[p1368] between each frame, and such that the content moves at most the distance given by the marquee scroll distance[p1368] with each frame.

When a marquee[p1367] element has a bgcolor attribute set, the value is expected to be parsed using the rules for parsing a legacy color value[p91], and if that does not return an error, the user agent is expected to treat the attribute as a presentational hint[p1326] setting the element's 'background-color' property to the resulting color.

The width and height attributes on a marquee[p1367] element map to the dimension properties[p1326] 'width' and 'height' on the element respectively.

The natural height of a marquee[p1367] element with its direction[p1368] attribute in the up[p1368] or down[p1368] states is 200 CSS pixels.

The vspace attribute of a marquee[p1367] element maps to the dimension properties[p1326] 'margin-top' and 'margin-bottom' on the element. The hspace attribute of a marquee[p1367] element maps to the dimension properties[p1326] 'margin-left' and 'margin-right' on the element.

The 'overflow' property on the marquee[p1367] element is expected to be ignored; overflow is expected to always be hidden.

15.5.13 The meter[p579] element §[p1352]

```
CSS
@namespace "http://www.w3.org/1999/xhtml";

meter { appearance: auto; }
```

The meter[p579] element is a devolvable widget. Its expected native appearance is to render as an 'inline-block' box with a 'block-size' of '1em' and a 'inline-size' of '5em', a 'vertical-align' of '-0.2em', and with its contents depicting a gauge.

When the element is wider than it is tall (or square), the depiction is expected to be of a horizontal gauge, with the minimum value on the right if the 'direction' property on this element has a computed value of 'rtl', and on the left otherwise. When the element is taller than it is wide, it is expected to depict a vertical gauge, with the minimum value on the bottom.

User agents are expected to use a presentation consistent with platform conventions for gauges, if any.

Note

Requirements for what must be depicted in the gauge are included in the definition of the meter[p579] element.

Need to detail the expected primitive appearance.

15.5.14 The progress[p577] element §[p1352]

```
CSS
@namespace "http://www.w3.org/1999/xhtml";

progress { appearance: auto; }
```

The progress[p577] element is a devolvable widget. Its expected native appearance is to render as an 'inline-block' box with a 'block-size' of '1em' and a 'inline-size' of '10em', and a 'vertical-align' of '-0.2em'.

When the element is wider than it is tall, the element is expected to be depicted as a horizontal progress bar, with the start on the right and the end on the left if the 'direction' property on this element has a computed value of 'rtl', and with the start on the left and the end on the right otherwise. When the element is taller than it is wide, it is expected to be depicted as a vertical progress bar, with the lowest value on the bottom. When the element is square, it is expected to be depicted as a direction-independent progress widget (e.g. a circular progress ring).

User agents are expected to use a presentation consistent with platform conventions for progress bars. In particular, user agents are expected to use different presentations for determinate and indeterminate progress bars. User agents are also expected to vary the presentation based on the dimensions of the element.

Example

For example, on some platforms for showing indeterminate progress there is a "spinner" progress indicator with square dimensions, which could be used when the element is square, and an indeterminate progress bar, which could be used when the element is wide.

Note

Requirements for how to determine if the progress bar is determinate or indeterminate, and what progress a determinate progress bar is to show, are included in the definition of the `progress`[p577] *element.*

Need to detail the expected primitive appearance.

15.5.15 The `select`[p559] element §[p1353]

A `select`[p559] element is either a **list box** or a **drop-down box**, depending on its attributes.

A `select`[p559] element whose `multiple`[p560] attribute is present is expected to render as a multi-select list box[p1353].

A `select`[p559] element whose `multiple`[p560] attribute is absent, and whose display size[p560] is greater than 1, is expected to render as a single-select list box[p1353].

When the element renders as a list box[p1353], it is a devolvable widget expected to render as an 'inline-block' box whose 'height' is the height necessary to contain as many rows for items as given by the element's display size[p560], or four rows if the attribute is absent, and whose 'width' is the width of the `select`'s labels[p1354] plus the width of a scrollbar.

A `select`[p559] element whose `multiple`[p560] attribute is absent, and whose display size[p560] is 1, is expected to render as an 'inline-block' one-line drop-down box[p1353] whose width is the width of the `select`'s labels[p1354].

When the element renders as a drop-down box[p1353], it is a devolvable widget. Its appearance in the devolved state, as well as its appearance when the computed value of the element's 'appearance' property is `'menulist-button'`, is that of a drop-down box, including a "drop-down button", but not necessarily rendered using a native control of the host operating system. In such a state, CSS properties such as 'color', 'background-color', and 'border' should not be disregarded (as is generally permissible when rendering an element according to its native appearance).

In either case (list box[p1353] or drop-down box[p1353]), the element's items are expected to be the element's list of options[p560], with the element's `optgroup`[p566] element children providing headers for groups of options where applicable.

An `optgroup`[p566] element is expected to be rendered by displaying the element's `label`[p566] attribute.

An `option`[p567] element is expected to be rendered by displaying the element's label[p568], indented under its `optgroup`[p566] element if it has one.

Each sequence of one or more child `hr`[p226] element siblings may be rendered as a single separator.

The **width of the select's labels** is the wider of the width necessary to render the widest optgroup[p566], and the width necessary to render the widest option[p567] element in the element's list of options[p560] (including its indent, if any).

If a select[p559] element contains a placeholder label option[p560], the user agent is expected to render that option[p567] in a manner that conveys that it is a label, rather than a valid option of the control. This can include preventing the placeholder label option[p560] from being explicitly selected by the user. When the placeholder label option[p560]'s selectedness[p568] is true, the control is expected to be displayed in a fashion that indicates that no valid option is currently selected.

User agents are expected to render the labels in a select[p559] in such a manner that any alignment remains consistent whether the label is being displayed as part of the page or in a menu control.

Need to detail the expected native appearance and primitive appearance.

15.5.16 The textarea[p570] element §[p1354]

The textarea[p570] element is a devolvable widget expected to render as an 'inline-block' box depicting a multiline text control. If this multiline text control provides a selection, then, when the user changes the current selection, the user agent is expected to queue an element task[p1073] on the user interaction task source[p1080] given the textarea[p570] element to fire an event named select[p1407] at the element, with the bubbles attribute initialized to true.

If the element has a cols[p572] attribute, and parsing that attribute's value using the rules for parsing non-negative integers[p74] doesn't generate an error, then the user agent is expected to use the attribute as a presentational hint[p1326] for the 'width' property on the element, with the value being the textarea effective width[p1354] (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the 'width' property on the element to the textarea effective width[p1354].

The **textarea effective width** of a textarea[p570] element is *size*×*avg* + *sbw*, where *size* is the element's character width[p572], *avg* is the average character width of the primary font of the element, in CSS pixels, and *sbw* is the width of a scrollbar, in CSS pixels. (The element's 'letter-spacing' property does not affect the result.)

If the element has a rows[p572] attribute, and parsing that attribute's value using the rules for parsing non-negative integers[p74] doesn't generate an error, then the user agent is expected to use the attribute as a presentational hint[p1326] for the 'height' property on the element, with the value being the textarea effective height[p1354] (as defined below). Otherwise, the user agent is expected to act as if it had a user-agent-level style sheet rule setting the 'height' property on the element to the textarea effective height[p1354].

The **textarea effective height** of a textarea[p570] element is the height in CSS pixels of the number of lines specified the element's character height[p572], plus the height of a scrollbar in CSS pixels.

User agents are expected to apply the 'white-space' CSS property to textarea[p570] elements. For historical reasons, if the element has a wrap[p572] attribute whose value is an ASCII case-insensitive match for the string "off", then the user agent is expected to treat the attribute as a presentational hint[p1326] setting the element's 'white-space' property to 'pre'.

Need to detail the expected native appearance and primitive appearance.

15.6 Frames and framesets §[p1354]

User agent are expected to render frameset[p1369] elements as a box with the height and width of the viewport, with a surface rendered according to the following layout algorithm:

1. The *cols* and *rows* variables are lists of zero or more pairs consisting of a number and a unit, the unit being one of *percentage*, *relative*, and *absolute*.

   Use the rules for parsing a list of dimensions[p78] to parse the value of the element's cols attribute, if there is one. Let *cols* be the result, or an empty list if there is no such attribute.

   Use the rules for parsing a list of dimensions[p78] to parse the value of the element's rows attribute, if there is one. Let *rows* be the result, or an empty list if there is no such attribute.

2. For any of the entries in *cols* or *rows* that have the number zero and the unit *relative*, change the entry's number to one.

3. If *cols* has no entries, then add a single entry consisting of the value 1 and the unit *relative* to *cols*.

   If *rows* has no entries, then add a single entry consisting of the value 1 and the unit *relative* to *rows*.

4. Invoke the algorithm defined below to convert a list of dimensions to a list of pixel values[p1356] using *cols* as the input list, and the width of the surface that the `frameset`[p1369] is being rendered into, in CSS pixels, as the input dimension. Let *sized cols* be the resulting list.

   Invoke the algorithm defined below to convert a list of dimensions to a list of pixel values[p1356] using *rows* as the input list, and the height of the surface that the `frameset`[p1369] is being rendered into, in CSS pixels, as the input dimension. Let *sized rows* be the resulting list.

5. Split the surface into a grid of *w*×*h* rectangles, where *w* is the number of entries in *sized cols* and *h* is the number of entries in *sized rows*.

   Size the columns so that each column in the grid is as many CSS pixels wide as the corresponding entry in the *sized cols* list.

   Size the rows so that each row in the grid is as many CSS pixels high as the corresponding entry in the *sized rows* list.

6. Let *children* be the list of `frame`[p1369] and `frameset`[p1369] elements that are children of the `frameset`[p1369] element for which the algorithm was invoked.

7. For each row of the grid of rectangles created in the previous step, from top to bottom, run these substeps:

   1. For each rectangle in the row, from left to right, run these substeps:

      1. If there are any elements left in *children*, take the first element in the list, and assign it to the rectangle.

         If this is a `frameset`[p1369] element, then recurse the entire `frameset`[p1369] layout algorithm for that `frameset`[p1369] element, with the rectangle as the surface.

         Otherwise, it is a `frame`[p1369] element; render its content navigable[p955], positioned and sized to fit the rectangle.

      2. If there are any elements left in *children*, remove the first element from *children*.

8. If the `frameset`[p1369] element has a border[p1355], draw an outer set of borders around the rectangles, using the element's frame border color[p1355].

   For each rectangle, if there is an element assigned to that rectangle, and that element has a border[p1355], draw an inner set of borders around that rectangle, using the element's frame border color[p1355].

   For each (visible) border that does not abut a rectangle that is assigned a `frame`[p1369] element with a `noresize` attribute (including rectangles in further nested `frameset`[p1369] elements), the user agent is expected to allow the user to move the border, resizing the rectangles within, keeping the proportions of any nested `frameset`[p1369] grids.

   A `frameset`[p1369] or `frame`[p1369] element **has a border** if the following algorithm returns true:

   1. If the element has a `frameborder` attribute whose value is not the empty string and whose first character is either a U+0031 DIGIT ONE (1) character, a U+0079 LATIN SMALL LETTER Y character (y), or a U+0059 LATIN CAPITAL LETTER Y character (Y), then return true.

   2. Otherwise, if the element has a `frameborder` attribute, return false.

   3. Otherwise, if the element has a parent element that is a `frameset`[p1369] element, then return true if *that* element has a border[p1355], and false if it does not.

   4. Otherwise, return true.

   The **frame border color** of a `frameset`[p1369] or `frame`[p1369] element is the color obtained from the following algorithm:

   1. If the element has a `bordercolor` attribute, and applying the rules for parsing a legacy color value[p91] to that attribute's value does not result in an error, then return the color so obtained.

   2. Otherwise, if the element has a parent element that is a `frameset`[p1369] element, then return the frame border color[p1355] of that element.

   3. Otherwise, return gray.

The algorithm to **convert a list of dimensions to a list of pixel values** consists of the following steps:

1. Let *input list* be the list of numbers and units passed to the algorithm.

   Let *output list* be a list of numbers the same length as *input list*, all zero.

   Entries in *output list* correspond to the entries in *input list* that have the same position.

2. Let *input dimension* be the size passed to the algorithm.

3. Let *count percentage* be the number of entries in *input list* whose unit is *percentage*.

   Let *total percentage* be the sum of all the numbers in *input list* whose unit is *percentage*.

   Let *count relative* be the number of entries in *input list* whose unit is *relative*.

   Let *total relative* be the sum of all the numbers in *input list* whose unit is *relative*.

   Let *count absolute* be the number of entries in *input list* whose unit is *absolute*.

   Let *total absolute* be the sum of all the numbers in *input list* whose unit is *absolute*.

   Let *remaining space* be the value of *input dimension*.

4. If *total absolute* is greater than *remaining space*, then for each entry in *input list* whose unit is *absolute*, set the corresponding value in *output list* to the number of the entry in *input list* multiplied by *remaining space* and divided by *total absolute*. Then, set *remaining space* to zero.

   Otherwise, for each entry in *input list* whose unit is *absolute*, set the corresponding value in *output list* to the number of the entry in *input list*. Then, decrement *remaining space* by *total absolute*.

5. If *total percentage* multiplied by the *input dimension* and divided by 100 is greater than *remaining space*, then for each entry in *input list* whose unit is *percentage*, set the corresponding value in *output list* to the number of the entry in *input list* multiplied by *remaining space* and divided by *total percentage*. Then, set *remaining space* to zero.

   Otherwise, for each entry in *input list* whose unit is *percentage*, set the corresponding value in *output list* to the number of the entry in *input list* multiplied by the *input dimension* and divided by 100. Then, decrement *remaining space* by *total percentage* multiplied by the *input dimension* and divided by 100.

6. For each entry in *input list* whose unit is *relative*, set the corresponding value in *output list* to the number of the entry in *input list* multiplied by *remaining space* and divided by *total relative*.

7. Return *output list*.

User agents working with integer values for frame widths (as opposed to user agents that can lay frames out with subpixel accuracy) are expected to distribute the remainder first to the last entry whose unit is *relative*, then equally (not proportionally) to each entry whose unit is *percentage*, then equally (not proportionally) to each entry whose unit is *absolute*, and finally, failing all else, to the last entry.

The contents of a `frame`[p1369] element that does not have a `frameset`[p1369] parent are expected to be rendered as transparent black; the user agent is expected to not render its content navigable[p955] in this case, and its content navigable[p955] is expected to have a viewport with zero width and zero height.

15.7 Interactive media §[p13 56]

15.7.1 Links, forms, and navigation §[p13 56]

User agents are expected to allow the user to control aspects of hyperlink[p297] activation and form submission[p617], such as which navigable[p952] is to be used for the subsequent navigation[p977].

User agents are expected to allow users to discover the destination of hyperlinks[p297] and of forms[p505] before triggering their navigation[p977].

User agents are expected to inform the user of whether a hyperlink[p297] includes hyperlink auditing[p307], and to let them know at a minimum which domains will be contacted as part of such auditing.

User agents may allow users to navigate[p977] navigables[p952] to the URLs indicated[p95] by the `cite` attributes on `q`[p261], `blockquote`[p229], `ins`[p329], and `del`[p331] elements.

User agents may surface hyperlinks[p297] created by `link`[p172] elements in their user interface, as discussed previously[p183].

15.7.2 The `title`[p154] attribute §[p1357]

User agents are expected to expose the advisory information[p154] of elements upon user request, and to make the user aware of the presence of such information.

On interactive graphical systems where the user can use a pointing device, this could take the form of a tooltip. When the user is unable to use a pointing device, then the user agent is expected to make the content available in some other fashion, e.g. by making the element a focusable area[p815] and always displaying the advisory information[p154] of the currently focused[p817] element, or by showing the advisory information[p154] of the elements under the user's finger on a touch device as the user pans around the screen.

U+000A LINE FEED (LF) characters are expected to cause line breaks in the tooltip; U+0009 CHARACTER TABULATION (tab) characters are expected to render as a nonzero horizontal shift that lines up the next glyph with the next tab stop, with tab stops occurring at points that are multiples of 8 times the width of a U+0020 SPACE character.

Example

For example, a visual user agent could make elements with a `title`[p154] attribute focusable[p817], and could make any focused[p817] element with a `title`[p154] attribute show its tooltip under the element while the element has focus. This would allow a user to tab around the document to find all the advisory text.

Example

As another example, a screen reader could provide an audio cue when reading an element with a tooltip, with an associated key to read the last tooltip for which a cue was played.

15.7.3 Editing hosts §[p1357]

The current text editing caret (i.e. the active range, if it is empty and in an editing host[p835]), if any, is expected to act like an inline replaced element with the vertical dimensions of the caret and with zero width for the purposes of the CSS rendering model.

Note

This means that even an empty block can have the caret inside it, and that when the caret is in such an element, it prevents margins from collapsing through the element.

15.7.4 Text rendered in native user interfaces §[p1357]

User agents are expected to honor the Unicode semantics of text that is exposed in user interfaces, for example supporting the bidirectional algorithm in text shown in dialogs, title bars, popup menus, and tooltips. Text from the contents of elements is expected to be rendered in a manner that honors the directionality[p157] of the element from which the text was obtained. Text from attributes is expected to be rendered in a manner that honours the directionality of the attribute[p158].

Example

Consider the following markup, which has Hebrew text asking for a programming language, the languages being text for which a left-to-right direction is important given the punctuation in some of their names:

```
<p dir="rtl" lang="he">
 <label>
  בחר שפת תכנות:
>  select>
   <option dir="ltr">C++</option>
```

```
    <option dir="ltr">C#</option>
    <option dir="ltr">FreePascal</option>
    <option dir="ltr">F#</option>
   </select>
  </label>
 </p>
```

If the select[p559] element was rendered as a drop down box, a correct rendering would ensure that the punctuation was the same both in the drop down, and in the box showing the current selection.

Example

The directionality of attributes depends on the attribute and on the element's dir[p156] attribute, as the following example demonstrates. Consider this markup:

```
<table>
 <tr>
  <th abbr="(א" dir=ltr>A
  <th abbr="(א" dir=rtl>A
  <th abbr="(א" dir=auto>A
</table>
```

If the abbr[p487] attributes are rendered, e.g. in a tooltip or other user interface, the first will have a left parenthesis (because the direction is 'ltr'), the second will have a right parenthesis (because the direction is 'rtl'), and the third will have a right parenthesis (because the direction is determined *from the attribute value* to be 'rtl').

However, if instead the attribute was not a directionality-capable attribute[p158], the results would be different:

```
<table>
 <tr>
  <th data-abbr="(א" dir=ltr>A
  <th data-abbr="(א" dir=rtl>A
  <th data-abbr="(א" dir=auto>A
</table>
```

In this case, if the user agent were to expose the `data-abbr` attribute in the user interface (e.g. in a debugging environment), the last case would be rendered with a *left* parenthesis, because the direction would be determined from the element's contents.

A string provided by a script (e.g. the argument to window.alert()[p1106]) is expected to be treated as an independent set of one or more bidirectional algorithm paragraphs when displayed, as defined by the bidirectional algorithm, including, for instance, supporting the paragraph-breaking behavior of U+000A LINE FEED (LF) characters. For the purposes of determining the paragraph level of such text in the bidirectional algorithm, this specification does *not* provide a higher-level override of rules P2 and P3. [BIDI][p1410]

When necessary, authors can enforce a particular direction for a given paragraph by starting it with the Unicode U+200E LEFT-TO-RIGHT MARK or U+200F RIGHT-TO-LEFT MARK characters.

Example

Thus, the following script:

```
alert('\u05DC\u05DE\u05D3 HTML \u05D4\u05D9\u05D5\u05DD!')
```

...would always result in a message reading "למד HTML היום!" (not "למד HTML היום!"), regardless of the language of the user agent interface or the direction of the page or any of its elements.

Example

For a more complex example, consider the following script:

```
/* Warning: this script does not handle right-to-left scripts correctly */
var s;
if (s = prompt('What is your name?')) {
  alert(s + '! Ok, Fred, ' + s + ', and Wilma will get the car.');
}
```

When the user enters "Kitty", the user agent would alert "Kitty! Ok, Fred, Kitty, and Wilma will get the car.". However, if the user enters "لا أفهم", then the bidirectional algorithm will determine that the direction of the paragraph is right-to-left, and so the output will be the following unintended mess: ".and Wilma will get the car ,لا أفهم ,Ok, Fred !لا أفهم"

To force an alert that starts with user-provided text (or other text of unknown directionality) to render left-to-right, the string can be prefixed with a U+200E LEFT-TO-RIGHT MARK character:

```
var s;
if (s = prompt('What is your name?')) {
  alert('\u200E' + s + '! Ok, Fred, ' + s + ', and Wilma will get the car.');
}
```

15.8 Print media §[p1359]

User agents are expected to allow the user to request the opportunity to **obtain a physical form** (or a representation of a physical form) of a Document[p127]. For example, selecting the option to print a page or convert it to PDF format. [PDF][p1415]

When the user actually obtains a physical form[p1359] (or a representation of a physical form) of a Document[p127], the user agent is expected to create a new rendering of the Document[p127] for the print media.

15.9 Unstyled XML documents §[p1359]

HTML user agents may, in certain circumstances, find themselves rendering non-HTML documents that use vocabularies for which they lack any built-in knowledge. This section provides for a way for user agents to handle such documents in a somewhat useful manner.

While a Document[p127] is an unstyled document[p1359], the user agent is expected to render an unstyled document view[p1360].

A Document[p127] is an **unstyled document** while it matches the following conditions:

- The Document[p127] has no author style sheets (whether referenced by HTTP headers, processing instructions, elements like link[p172], inline elements like style[p195], or any other mechanism).
- None of the elements in the Document[p127] have any presentational hints[p1326].
- None of the elements in the Document[p127] have any style attributes.
- None of the elements in the Document[p127] are in any of the following namespaces: HTML namespace, SVG namespace, MathML namespace
- The Document[p127] has no focusable area[p815] (e.g. from XLink) other than the viewport.
- The Document[p127] has no hyperlinks[p297] (e.g. from XLink).
- There exists no script[p1040] whose settings object[p1040]'s global object[p1033] is a Window[p892] object with this Document[p127] as its

associated Document[p894].

- None of the elements in the Document[p127] have any registered event listeners.

An unstyled document view is one where the DOM is not rendered according to CSS (which would, since there are no applicable styles in this context, just result in a wall of text), but is instead rendered in a manner that is useful for a developer. This could consist of just showing the Document[p127] object's source, maybe with syntax highlighting, or it could consist of displaying just the DOM tree, or simply a message saying that the page is not a styled document.

Note

If a Document[p127] stops being an unstyled document[p1359], then the conditions above stop applying, and thus a user agent following these requirements will switch to using the regular CSS rendering.

16 Obsolete features §p1361

16.1 Obsolete but conforming features §p1361

Features listed in this section will trigger warnings in conformance checkers.

Authors should not specify a border[p1366] attribute on an img[p338] element. If the attribute is present, its value must be the string "0". CSS should be used instead.

Authors should not specify a charset[p1363] attribute on a script[p638] element. If the attribute is present, its value must be an ASCII case-insensitive match for "utf-8". (This has no effect in a document that conforms to the requirements elsewhere in this standard of being encoded as UTF-8.)

Authors should not specify a language[p1365] attribute on a script[p638] element. If the attribute is present, its value must be an ASCII case-insensitive match for the string "JavaScript" and either the type[p639] attribute must be omitted or its value must be an ASCII case-insensitive match for the string "text/javascript". The attribute should be entirely omitted instead (with the value "JavaScript", it has no effect), or replaced with use of the type[p639] attribute.

Authors should not specify a value for the type[p639] attribute on script[p638] elements that is the empty string or a JavaScript MIME type essence match. Instead, they should omit the attribute, which has the same effect.

Authors should not specify a type[p1365] attribute on a style[p195] element. If the attribute is present, its value must be an ASCII case-insensitive match for "text/css[p1409]".

Authors should not specify the name[p1363] attribute on a[p252] elements. If the attribute is present, its value must not be the empty string and must neither be equal to the value of any of the IDs in the element's tree other than the element's own ID, if any, nor be equal to the value of any of the other name[p1363] attributes on a[p252] elements in the element's tree. If this attribute is present and the element has an ID, then the attribute's value must be equal to the element's ID. In earlier versions of the language, this attribute was intended as a way to specify possible targets for fragments in URLs. The id[p151] attribute should be used instead.

Authors should not, but may despite requirements to the contrary elsewhere in this specification, specify the maxlength[p541] and size[p542] attributes on input[p512] elements whose type[p514] attributes are in the Number[p528] state. One valid reason for using these attributes regardless is to help legacy user agents that do not support input[p512] elements with type="number" to still render the text control with a useful width.

16.1.1 Warnings for obsolete but conforming features §p1361

To ease the transition from HTML4 Transitional documents to the language defined in *this* specification, and to discourage certain features that are only allowed in very few circumstances, conformance checkers must warn the user when the following features are used in a document. These are generally old obsolete features that have no effect, and are allowed only to distinguish between likely mistakes (regular conformance errors) and mere vestigial markup or unusual and discouraged practices (these warnings).

The following features must be categorized as described above:

- The presence of a border[p1366] attribute on an img[p338] element if its value is the string "0".
- The presence of a charset[p1363] attribute on a script[p638] element if its value is an ASCII case-insensitive match for "utf-8".
- The presence of a language[p1365] attribute on a script[p638] element if its value is an ASCII case-insensitive match for the string "JavaScript" and if there is no type[p639] attribute or there is and its value is an ASCII case-insensitive match for the string "text/javascript".
- The presence of a type[p1365] attribute on a script[p638] element if its value is a JavaScript MIME type essence match.
- The presence of a type[p1365] attribute on a style[p195] element if its value is an ASCII case-insensitive match for "text/css[p1409]".
- The presence of a name[p1363] attribute on an a[p252] element, if its value is not the empty string.
- The presence of a maxlength[p541] attribute on an input[p512] element whose type[p514] attribute is in the Number[p528] state.

- The presence of a size[p542] attribute on an input[p512] element whose type[p514] attribute is in the Number[p528] state.

Conformance checkers must distinguish between pages that have no conformance errors and have none of these obsolete features, and pages that have no conformance errors but do have some of these obsolete features.

Example

For example, a validator could report some pages as "Valid HTML" and others as "Valid HTML with warnings".

16.2 Non-conforming features §[p1362]

Elements in the following list are entirely obsolete, and must not be used by authors:

applet

Use embed[p391] or object[p394] instead.

acronym

Use abbr[p263] instead.

bgsound

Use audio[p402] instead.

dir

Use ul[p234] instead.

frame[p1369]

frameset[p1369]

noframes

Either use iframe[p383] and CSS instead, or use server-side includes to generate complete pages with the various invariant parts merged in.

isindex

Use an explicit form[p505] and text control[p519] combination instead.

keygen

For enterprise device management use cases, use native on-device management capabilities.

For certificate enrollment use cases, use the Web Cryptography API to generate a keypair for the certificate, and then export the certificate and key to allow the user to install them manually. [WEBCRYPTO][p1418]

listing

Use pre[p228] and code[p281] instead.

menuitem

To implement a custom context menu, use script to handle the contextmenu event.

nextid

Use GUIDs instead.

noembed

Use object[p394] instead of embed[p391] when fallback is necessary.

param

Use the data[p395] attribute of the object[p394] element to set the URL of the external resource.

plaintext

Use the "text/plain" MIME type instead.

rb

rtc

Providing the ruby base directly inside the ruby[p265] element or using nested ruby[p265] elements is sufficient.

strike

Use del[p331] instead if the element is marking an edit, otherwise use s[p259] instead.

xmp

Use pre[p228] and code[p281] instead, and escape "<" and "&" characters as "<" and "&" respectively.

basefont

big

blink

center

font

marquee[p1367]

multicol

nobr

spacer

tt

Use appropriate elements or CSS instead.

Where the tt[p1363] element would have been used for marking up keyboard input, consider the kbd[p284] element; for variables, consider the var[p282] element; for computer code, consider the code[p281] element; and for computer output, consider the samp[p283] element.

Similarly, if the big[p1363] element is being used to denote a heading, consider using the h1[p211] element; if it is being used for marking up important passages, consider the strong[p256] element; and if it is being used for highlighting text for reference purposes, consider the mark[p289] element.

See also the text-level semantics usage summary[p296] for more suggestions with examples.

The following attributes are obsolete (though the elements are still part of the language), and must not be used by authors:

charset on a[p252] elements

charset on link[p172] elements

Use an HTTP `Content-Type[p96]` header on the linked resource instead.

charset on script[p638] elements (except as noted in the previous section)

Omit the attribute. Both documents and scripts are required to use UTF-8, so it is redundant to specify it on the script[p638] element since it inherits from the document.

coords on a[p252] elements

shape on a[p252] elements

Use area[p463] instead of a[p252] for image maps.

methods on a[p252] elements

methods on link[p172] elements

Use the HTTP OPTIONS feature instead.

name on a[p252] elements (except as noted in the previous section)

name on embed[p391] elements

name on img[p338] elements

name on option[p567] elements

Use the id[p151] attribute instead.

`rev` on `a`[p252] elements

`rev` on `link`[p172] elements

Use the `rel`[p297] attribute instead, with an opposite term. (For example, instead of `rev="made"`, use `rel="author"`.)

`urn` on `a`[p252] elements

`urn` on `link`[p172] elements

Specify the preferred persistent identifier using the `href`[p297] attribute instead.

`accept` on `form`[p505] elements

Use the `accept`[p535] attribute directly on the `input`[p512] elements instead.

`hreflang` on `area`[p463] elements

`type` on `area`[p463] elements

These attributes do not do anything useful, and for historical reasons there are no corresponding IDL attributes on `area`[p463] elements. Omit them altogether.

`nohref` on `area`[p463] elements

Omitting the `href`[p297] attribute is sufficient; the `nohref`[p1364] attribute is unnecessary. Omit it altogether.

`profile` on `head`[p168] elements

Unnecessary. Omit it altogether.

`manifest` on `html`[p167] elements

Use service workers instead. [SW][p1417]

`version` on `html`[p167] elements

Unnecessary. Omit it altogether.

`ismap` on `input`[p512] elements

Unnecessary. Omit it altogether. All `input`[p512] elements with a `type`[p514] attribute in the Image Button[p538] state are processed as server-side image maps.

`usemap` on `input`[p512] elements

`usemap` on `object`[p394] elements

Use the `img`[p338] element for image maps.

`longdesc` on `iframe`[p383] elements

`longdesc` on `img`[p338] elements

Use a regular `a`[p252] element to link to the description, or (in the case of images) use an image map[p464] to provide a link from the image to the image's description.

`lowsrc` on `img`[p338] elements

Use a progressive JPEG image (given in the `src`[p340] attribute), instead of using two separate images.

`target` on `link`[p172] elements

Unnecessary. Omit it altogether.

`type` on `menu`[p235] elements

To implement a custom context menu, use script to handle the `contextmenu` event. For toolbar menus, omit the attribute.

`label` on `menu`[p235] elements

`contextmenu` on all elements

`onshow` on all elements

To implement a custom context menu, use script to handle the `contextmenu` event.

`scheme` on `meta`[p184] elements

Use only one scheme per field, or make the scheme declaration part of the value.

archive on object[p394] elements

classid on object[p394] elements

code on object[p394] elements

codebase on object[p394] elements

codetype on object[p394] elements

Use the data[p395] and type[p395] attributes to invoke plugins[p46].

declare on object[p394] elements

Repeat the object[p394] element completely each time the resource is to be reused.

standby on object[p394] elements

Optimize the linked resource so that it loads quickly or, at least, incrementally.

typemustmatch on object[p394] elements

Avoid using object[p394] elements with untrusted resources.

language on script[p638] elements (except as noted in the previous section)

Omit the attribute for JavaScript; for data blocks[p640], use the type[p639] attribute instead.

event on script[p638] elements

for on script[p638] elements

Use DOM events mechanisms to register event listeners. [DOM][p1412]

type on style[p195] elements (except as noted in the previous section)

Omit the attribute for CSS; for data blocks[p640], use script[p638] as the container instead of style[p195].

datapagesize on table[p469] elements

Unnecessary. Omit it altogether.

summary on table[p469] elements

Use one of the techniques for describing tables[p474] given in the table[p469] section instead.

abbr on td[p484] elements

Use text that begins in an unambiguous and terse manner, and include any more elaborate text after that. The title[p154] attribute can also be useful in including more detailed text, so that the cell's contents can be made terse. If it's a heading, use th[p486] (which has an abbr[p487] attribute).

axis on td[p484] and th[p486] elements

Use the scope[p486] attribute on the relevant th[p486].

scope on td[p484] elements

Use th[p486] elements for heading cells.

datasrc on a[p252], button[p556], div[p251], frame[p1369], iframe[p383], img[p338], input[p512], label[p509], legend[p586], marquee[p1367], object[p394], option[p567], select[p559], span[p293], table[p469], and textarea[p570] elements

datafld on a[p252], button[p556], div[p251], fieldset[p584], frame[p1369], iframe[p383], img[p338], input[p512], label[p509], legend[p586], marquee[p1367], object[p394], select[p559], span[p293], and textarea[p570] elements

dataformatas on button[p556], div[p251], input[p512], label[p509], legend[p586], marquee[p1367], object[p394], option[p567], select[p559], span[p293], and table[p469] elements

Use script and a mechanism such as XMLHttpRequest to populate the page dynamically. [XHR][p1419]

dropzone on all elements

Use script to handle the dragenter[p856] and dragover[p856] events instead.

alink on body[p199] elements
bgcolor on body[p199] elements
bottommargin on body[p199] elements
leftmargin on body[p199] elements
link on body[p199] elements

type on **ul**[p234] elements
background on **body**[p199], **table**[p469], **thead**[p481], **tbody**[p480], **tfoot**[p482], **tr**[p483], **td**[p484], and **th**[p486] elements

Use CSS instead.

16.3 Requirements for implementations §[p13 67]

16.3.1 The marquee element §[p13 67]

The marquee[p1367] element is a presentational element that animates content. CSS transitions and animations are a more appropriate mechanism. [CSSANIMATIONS][p1411] [CSSTRANSITIONS][p1412]

The marquee[p1367] element must implement the HTMLMarqueeElement[p1367] interface.

IDL
```
[Exposed=Window]
interface HTMLMarqueeElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString behavior;
  [CEReactions] attribute DOMString bgColor;
  [CEReactions] attribute DOMString direction;
```

```
  [CEReactions] attribute DOMString height;
  [CEReactions] attribute unsigned long hspace;
  [CEReactions] attribute long loop;
  [CEReactions] attribute unsigned long scrollAmount;
  [CEReactions] attribute unsigned long scrollDelay;
  [CEReactions] attribute boolean trueSpeed;
  [CEReactions] attribute unsigned long vspace;
  [CEReactions] attribute DOMString width;

  undefined start();
  undefined stop();
};
```

A `marquee`[p1367] element can be **turned on** or **turned off**. When it is created, it is turned on[p1368].

When the **`start()`** method is called, the `marquee`[p1367] element must be turned on[p1368].

When the **`stop()`** method is called, the `marquee`[p1367] element must be turned off[p1368].

The **`behavior`** content attribute on `marquee`[p1367] elements is an enumerated attribute[p73] with the following keywords (all non-conforming):

Keyword	State
`scroll`	**scroll**
`slide`	**slide**
`alternate`	**alternate**

The *missing value default*[p73] and *invalid value default*[p73] are the scroll[p1368] state.

The **`direction`** content attribute on `marquee`[p1367] elements is an enumerated attribute[p73] with the following keywords (all non-conforming):

Keyword	State
`left`	**left**
`right`	**right**
`up`	**up**
`down`	**down**

The *missing value default*[p73] and *invalid value default*[p73] are the left[p1368] state.

The **`truespeed`** content attribute on `marquee`[p1367] elements is a boolean attribute[p72].

A `marquee`[p1367] element has a **marquee scroll interval**, which is obtained as follows:

1. If the element has a `scrolldelay` attribute, and parsing its value using the rules for parsing non-negative integers[p74] does not return an error, then let *delay* be the parsed value. Otherwise, let *delay* be 85.
2. If the element does not have a `truespeed`[p1368] attribute, and the *delay* value is less than 60, then let *delay* be 60 instead.
3. The marquee scroll interval[p1368] is *delay*, interpreted in milliseconds.

A `marquee`[p1367] element has a **marquee scroll distance**, which, if the element has a `scrollamount` attribute, and parsing its value using the rules for parsing non-negative integers[p74] does not return an error, is the parsed value interpreted in CSS pixels, and otherwise is 6 CSS pixels.

A marquee[p1367] element has a **marquee loop count**, which, if the element has a **loop** attribute, and parsing its value using the rules for parsing integers[p74] does not return an error or a number less than 1, is the parsed value, and otherwise is −1.

The **loop** IDL attribute, on getting, must return the element's marquee loop count[p1369]; and on setting, if the new value is different than the element's marquee loop count[p1369] and either greater than zero or equal to −1, must set the element's loop[p1369] content attribute (adding it if necessary) to the valid integer[p74] that represents the new value. (Other values are ignored.)

A marquee[p1367] element also has a **marquee current loop index**, which is zero when the element is created.

The rendering layer will occasionally **increment the marquee current loop index**, which must cause the following steps to be run:

1. If the marquee loop count[p1369] is −1, then return.
2. Increment the marquee current loop index[p1369] by one.
3. If the marquee current loop index[p1369] is now equal to or greater than the element's marquee loop count[p1369], turn off[p1368] the marquee[p1367] element.

The **behavior**, **direction**, **height**, **hspace**, **vspace**, and **width** IDL attributes must reflect[p101] the respective content attributes of the same name.

The **bgColor** IDL attribute must reflect[p101] the `bgcolor` content attribute.

The **scrollAmount** IDL attribute must reflect[p101] the `scrollamount` content attribute. The default value[p104] is 6.

The **scrollDelay** IDL attribute must reflect[p101] the `scrolldelay` content attribute. The default value[p104] is 85.

The **trueSpeed** IDL attribute must reflect[p101] the truespeed[p1368] content attribute.

16.3.2 Frames §[p1369]

The **frameset** element acts as the body element[p133] in documents that use frames.

The frameset[p1369] element must implement the HTMLFrameSetElement[p1369] interface.

IDL
```
[Exposed=Window]
interface HTMLFrameSetElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString cols;
  [CEReactions] attribute DOMString rows;
};
HTMLFrameSetElement includes WindowEventHandlers;
```

The **cols** and **rows** IDL attributes of the frameset[p1369] element must reflect[p101] the respective content attributes of the same name.

The frameset[p1369] element exposes as event handler content attributes[p1084] a number of the event handlers[p1083] of the Window[p892] object. It also mirrors their event handler IDL attributes[p1084].

The event handlers[p1083] of the Window[p892] object named by the Window-reflecting body element event handler set[p1091], exposed on the frameset[p1369] element, replace the generic event handlers[p1083] with the same names normally supported by HTML elements[p45].

The **frame** element has a content navigable[p955] similar to the iframe[p383] element, but rendered within a frameset[p1369] element.

A frame[p1369] element is said to be an **active frame element** when it is in a document tree and its node document's browsing context[p961] is non-null.

When a frame[p1369] element *element* is created as an active frame element[p1369], or becomes an active frame element[p1369] after not having been one, the user agent must run these steps:

1. Create a new child navigable[p955] for *element*.

2. Process the frame attributes[p1370] for *element*, with *initialInsertion*[p1370] set to true.

When a frame[p1369] element stops being an active frame element[p1369], the user agent must destroy a child navigable[p958] given the element.

Whenever a frame[p1369] element with a non-null content navigable[p955] has its `src` attribute set, changed, or removed, the user agent must process the frame attributes[p1370].

To **process the frame attributes** for an element *element*, with an optional boolean ***initialInsertion***:

1. Let *url* be the result of running the shared attribute processing steps for iframe and frame elements[p386] given *element* and *initialInsertion*.

2. If *url* is null, then return.

3. If *url* matches about:blank[p94] and *initialInsertion* is true, then:

    1. Fire an event named load[p1407] at *element*.

    2. Return.

4. Navigate an iframe or frame[p386] given *element*, *url*, and the empty string.

The frame[p1369] element potentially delays the load event[p387].

The frame[p1369] element must implement the HTMLFrameElement[p1370] interface.

IDL
```
[Exposed=Window]
interface HTMLFrameElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString scrolling;
  [CEReactions] attribute USVString src;
  [CEReactions] attribute DOMString frameBorder;
  [CEReactions] attribute USVString longDesc;
  [CEReactions] attribute boolean noResize;
  readonly attribute Document? contentDocument;
  readonly attribute WindowProxy? contentWindow;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginHeight;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginWidth;
};
```

The **name**, **scrolling**, and **src** IDL attributes of the frame[p1369] element must reflect[p101] the respective content attributes of the same name. For the purposes of reflection, the frame[p1369] element's `src` content attribute is defined as containing a URL.

The **frameBorder** IDL attribute of the frame[p1369] element must reflect[p101] the element's `frameborder` content attribute.

The **longDesc** IDL attribute of the frame[p1369] element must reflect[p101] the element's `longdesc` content attribute, which for the purposes of reflection is defined as containing a URL.

The **noResize** IDL attribute of the frame[p1369] element must reflect[p101] the element's `noresize` content attribute.

The **marginHeight** IDL attribute of the frame[p1369] element must reflect[p101] the element's `marginheight` content attribute.

The **marginWidth** IDL attribute of the frame[p1369] element must reflect[p101] the element's `marginwidth` content attribute.

The **contentDocument** getter steps are to return this's content document[p955].

The **contentWindow** getter steps are to return this's content window[p955].

16.3.3 Other elements, attributes and APIs §[p1371]

User agents must treat acronym[p1362] elements in a manner equivalent to abbr[p263] elements in terms of semantics and for purposes of rendering.

IDL
```
partial interface HTMLAnchorElement {
  [CEReactions] attribute DOMString coords;
  [CEReactions] attribute DOMString charset;
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString rev;
  [CEReactions] attribute DOMString shape;
};
```

The **coords**, **charset**, **name**, **rev**, and **shape** IDL attributes of the a[p252] element must reflect[p101] the respective content attributes of the same name.

IDL
```
partial interface HTMLAreaElement {
  [CEReactions] attribute boolean noHref;
};
```

The **noHref** IDL attribute of the area[p463] element must reflect[p101] the element's nohref[p1364] content attribute.

IDL
```
partial interface HTMLBodyElement {
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString text;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString link;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString vLink;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString aLink;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
  [CEReactions] attribute DOMString background;
};
```

The **text** IDL attribute of the body[p199] element must reflect[p101] the element's text[p1366] content attribute.

The **link** IDL attribute of the body[p199] element must reflect[p101] the element's link[p1366] content attribute.

The **aLink** IDL attribute of the body[p199] element must reflect[p101] the element's alink[p1366] content attribute.

The **vLink** IDL attribute of the body[p199] element must reflect[p101] the element's vlink[p1366] content attribute.

The **bgColor** IDL attribute of the body[p199] element must reflect[p101] the element's bgcolor[p1366] content attribute.

The **background** IDL attribute of the body[p199] element must reflect[p101] the element's background[p1367] content attribute. (The background[p1367] content is *not* defined to contain a URL, despite rules regarding its handling in the Rendering section above.)

IDL
```
partial interface HTMLBRElement {
  [CEReactions] attribute DOMString clear;
};
```

The **clear** IDL attribute of the br[p294] element must reflect[p101] the content attribute of the same name.

IDL
```
partial interface HTMLTableCaptionElement {
  [CEReactions] attribute DOMString align;
};
```

The **align** IDL attribute of the caption[p477] element must reflect[p101] the content attribute of the same name.

```
IDL
partial interface HTMLTableColElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString ch;
  [CEReactions] attribute DOMString chOff;
  [CEReactions] attribute DOMString vAlign;
  [CEReactions] attribute DOMString width;
};
```

The **align** and **width** IDL attributes of the col[p479] element must reflect[p101] the respective content attributes of the same name.

The **ch** IDL attribute of the col[p479] element must reflect[p101] the element's char[p1366] content attribute.

The **chOff** IDL attribute of the col[p479] element must reflect[p101] the element's charoff[p1366] content attribute.

The **vAlign** IDL attribute of the col[p479] element must reflect[p101] the element's valign[p1366] content attribute.

User agents must treat dir[p1362] elements in a manner equivalent to ul[p234] elements in terms of semantics and for purposes of rendering.

The dir[p1362] element must implement the HTMLDirectoryElement[p1372] interface.

```
IDL
[Exposed=Window]
interface HTMLDirectoryElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute boolean compact;
};
```

The **compact** IDL attribute of the dir[p1362] element must reflect[p101] the content attribute of the same name.

```
IDL
partial interface HTMLDivElement {
  [CEReactions] attribute DOMString align;
};
```

The **align** IDL attribute of the div[p251] element must reflect[p101] the content attribute of the same name.

```
IDL
partial interface HTMLDListElement {
  [CEReactions] attribute boolean compact;
};
```

The **compact** IDL attribute of the dl[p238] element must reflect[p101] the content attribute of the same name.

```
IDL
partial interface HTMLEmbedElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString name;
};
```

The **name** and **align** IDL attributes of the embed[p391] element must reflect[p101] the respective content attributes of the same name.

The font[p1363] element must implement the HTMLFontElement[p1372] interface.

```
IDL
[Exposed=Window]
interface HTMLFontElement : HTMLElement {
  [HTMLConstructor] constructor();
```

```
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString color;
  [CEReactions] attribute DOMString face;
  [CEReactions] attribute DOMString size;
};
```

The **color**, **face**, and **size** IDL attributes of the font[p1363] element must reflect[p101] the respective content attributes of the same name.

IDL
```
partial interface HTMLHeadingElement {
  [CEReactions] attribute DOMString align;
};
```

The **align** IDL attribute of the h1[p211]–h6[p211] elements must reflect[p101] the content attribute of the same name.

Note

*The **profile** IDL attribute on head[p168] elements (with the HTMLHeadElement[p168] interface) is intentionally omitted. Unless so required by another applicable specification[p70], implementations would therefore not support this attribute. (It is mentioned here as it was defined in a previous version of DOM.)*

IDL
```
partial interface HTMLHRElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString color;
  [CEReactions] attribute boolean noShade;
  [CEReactions] attribute DOMString size;
  [CEReactions] attribute DOMString width;
};
```

The **align**, **color**, **size**, and **width** IDL attributes of the hr[p226] element must reflect[p101] the respective content attributes of the same name.

The **noShade** IDL attribute of the hr[p226] element must reflect[p101] the element's noshade[p1366] content attribute.

IDL
```
partial interface HTMLHtmlElement {
  [CEReactions] attribute DOMString version;
};
```

The **version** IDL attribute of the html[p167] element must reflect[p101] the content attribute of the same name.

IDL
```
partial interface HTMLIFrameElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString scrolling;
  [CEReactions] attribute DOMString frameBorder;
  [CEReactions] attribute USVString longDesc;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginHeight;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString marginWidth;
};
```

The **align** and **scrolling** IDL attributes of the iframe[p383] element must reflect[p101] the respective content attributes of the same name.

The **frameBorder** IDL attribute of the iframe[p383] element must reflect[p101] the element's frameborder[p1366] content attribute.

The **longDesc** IDL attribute of the iframe[p383] element must reflect[p101] the element's longdesc[p1364] content attribute, which for the purposes of reflection is defined as containing a URL.

The **marginHeight** IDL attribute of the iframe[p383] element must reflect[p101] the element's marginheight[p1366] content attribute.

The **marginWidth** IDL attribute of the iframe[p383] element must reflect[p101] the element's marginwidth[p1366] content attribute.

IDL
```
partial interface HTMLImageElement {
  [CEReactions] attribute DOMString name;
  [CEReactions] attribute USVString lowsrc;
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute unsigned long hspace;
  [CEReactions] attribute unsigned long vspace;
  [CEReactions] attribute USVString longDesc;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString border;
};
```

The **name**, **align**, **border**, **hspace**, and **vspace** IDL attributes of the img[p338] element must reflect[p101] the respective content attributes of the same name.

The **longDesc** IDL attribute of the img[p338] element must reflect[p101] the element's longdesc[p1364] content attribute, which for the purposes of reflection is defined as containing a URL.

The **lowsrc** IDL attribute of the img[p338] element must reflect[p101] the element's lowsrc[p1364] content attribute, which for the purposes of reflection is defined as containing a URL.

IDL
```
partial interface HTMLInputElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString useMap;
};
```

The **align** IDL attribute of the input[p512] element must reflect[p101] the content attribute of the same name.

The **useMap** IDL attribute of the input[p512] element must reflect[p101] the element's usemap[p1364] content attribute.

IDL
```
partial interface HTMLLegendElement {
  [CEReactions] attribute DOMString align;
};
```

The **align** IDL attribute of the legend[p586] element must reflect[p101] the content attribute of the same name.

IDL
```
partial interface HTMLLIElement {
  [CEReactions] attribute DOMString type;
};
```

The **type** IDL attribute of the li[p236] element must reflect[p101] the content attribute of the same name.

IDL
```
partial interface HTMLLinkElement {
  [CEReactions] attribute DOMString charset;
  [CEReactions] attribute DOMString rev;
  [CEReactions] attribute DOMString target;
};
```

The **charset**, **rev**, and **target** IDL attributes of the link[p172] element must reflect[p101] the respective content attributes of the same name.

User agents must treat listing[p1362] elements in a manner equivalent to pre[p228] elements in terms of semantics and for purposes of rendering.

IDL
```
partial interface HTMLMenuElement {
  [CEReactions] attribute boolean compact;
};
```

The **compact** IDL attribute of the menu[p235] element must reflect[p101] the content attribute of the same name.

IDL
```
partial interface HTMLMetaElement {
  [CEReactions] attribute DOMString scheme;
};
```

User agents may treat the scheme[p1364] content attribute on the meta[p184] element as an extension of the element's name[p185] content attribute when processing a meta[p184] element with a name[p185] attribute whose value is one that the user agent recognizes as supporting the scheme[p1364] attribute.

User agents are encouraged to ignore the scheme[p1364] attribute and instead process the value given to the metadata name as if it had been specified for each expected value of the scheme[p1364] attribute.

Example

For example, if the user agent acts on meta[p184] elements with name[p185] attributes having the value "eGMS.subject.keyword", and knows that the scheme[p1364] attribute is used with this metadata name, then it could take the scheme[p1364] attribute into account, acting as if it was an extension of the name[p185] attribute. Thus the following two meta[p184] elements could be treated as two elements giving values for two different metadata names, one consisting of a combination of "eGMS.subject.keyword" and "LGCL", and the other consisting of a combination of "eGMS.subject.keyword" and "ORLY":

```
<!-- this markup is invalid -->
<meta name="eGMS.subject.keyword" scheme="LGCL" content="Abandoned vehicles">
<meta name="eGMS.subject.keyword" scheme="ORLY" content="Mah car: kthxbye">
```

The suggested processing of this markup, however, would be equivalent to the following:

```
<meta name="eGMS.subject.keyword" content="Abandoned vehicles">
<meta name="eGMS.subject.keyword" content="Mah car: kthxbye">
```

The **scheme** IDL attribute of the meta[p184] element must reflect[p101] the content attribute of the same name.

IDL
```
partial interface HTMLObjectElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString archive;
  [CEReactions] attribute DOMString code;
  [CEReactions] attribute boolean declare;
  [CEReactions] attribute unsigned long hspace;
  [CEReactions] attribute DOMString standby;
  [CEReactions] attribute unsigned long vspace;
  [CEReactions] attribute DOMString codeBase;
  [CEReactions] attribute DOMString codeType;
  [CEReactions] attribute DOMString useMap;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString border;
};
```

The **align**, **archive**, **border**, **code**, **declare**, **hspace**, **standby**, and **vspace** IDL attributes of the object[p394] element must reflect[p101] the respective content attributes of the same name.

The **codeBase** IDL attribute of the object[p394] element must reflect[p101] the element's codebase[p1365] content attribute, which for the purposes of reflection is defined as containing a URL.

The **codeType** IDL attribute of the object[p394] element must reflect[p101] the element's codetype[p1365] content attribute.

The **useMap** IDL attribute must reflect[p101] the usemap[p465] content attribute.

```
IDL
partial interface HTMLOListElement {
  [CEReactions] attribute boolean compact;
};
```

The **compact** IDL attribute of the ol[p232] element must reflect[p101] the content attribute of the same name.

```
IDL
partial interface HTMLParagraphElement {
  [CEReactions] attribute DOMString align;
};
```

The **align** IDL attribute of the p[p223] element must reflect[p101] the content attribute of the same name.

The param[p1362] element must implement the HTMLParamElement[p1376] interface.

```
IDL
[Exposed=Window]
interface HTMLParamElement : HTMLElement {
  [HTMLConstructor] constructor();

  [CEReactions] attribute DOMString name;
  [CEReactions] attribute DOMString value;
  [CEReactions] attribute DOMString type;
  [CEReactions] attribute DOMString valueType;
};
```

The **name**, **value**, and **type** IDL attributes of the param[p1362] element must reflect[p101] the respective content attributes of the same name.

The **valueType** IDL attribute of the param[p1362] element must reflect[p101] the element's `valuetype` content attribute.

User agents must treat plaintext[p1362] elements in a manner equivalent to pre[p228] elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element, though.)

```
IDL
partial interface HTMLPreElement {
  [CEReactions] attribute long width;
};
```

The **width** IDL attribute of the pre[p228] element must reflect[p101] the content attribute of the same name.

```
IDL
partial interface HTMLStyleElement {
  [CEReactions] attribute DOMString type;
};
```

The **type** IDL attribute of the style[p195] element must reflect[p101] the element's type[p1365] content attribute.

```
IDL
partial interface HTMLScriptElement {
  [CEReactions] attribute DOMString charset;
  [CEReactions] attribute DOMString event;
  [CEReactions] attribute DOMString htmlFor;
};
```

The **charset** and **event** IDL attributes of the script[p638] element must reflect[p101] the respective content attributes of the same name.

The **htmlFor** IDL attribute of the script[p638] element must reflect[p101] the element's for[p1365] content attribute.

```
IDL
partial interface HTMLTableElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString border;
  [CEReactions] attribute DOMString frame;
  [CEReactions] attribute DOMString rules;
  [CEReactions] attribute DOMString summary;
  [CEReactions] attribute DOMString width;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString cellPadding;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString cellSpacing;
};
```

The **align**, **border**, **frame**, **summary**, **rules**, and **width**, IDL attributes of the table[p469] element must reflect[p101] the respective content attributes of the same name.

The **bgColor** IDL attribute of the table[p469] element must reflect[p101] the element's bgcolor[p1367] content attribute.

The **cellPadding** IDL attribute of the table[p469] element must reflect[p101] the element's cellpadding[p1367] content attribute.

The **cellSpacing** IDL attribute of the table[p469] element must reflect[p101] the element's cellspacing[p1367] content attribute.

```
IDL
partial interface HTMLTableSectionElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString ch;
  [CEReactions] attribute DOMString chOff;
  [CEReactions] attribute DOMString vAlign;
};
```

The **align** IDL attribute of the tbody[p480], thead[p481], and tfoot[p482] elements must reflect[p101] the content attribute of the same name.

The **ch** IDL attribute of the tbody[p480], thead[p481], and tfoot[p482] elements must reflect[p101] the elements' char[p1367] content attributes.

The **chOff** IDL attribute of the tbody[p480], thead[p481], and tfoot[p482] elements must reflect[p101] the elements' charoff[p1367] content attributes.

The **vAlign** IDL attribute of the tbody[p480], thead[p481], and tfoot[p482] element must reflect[p101] the elements' valign[p1367] content attributes.

```
IDL
partial interface HTMLTableCellElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString axis;
  [CEReactions] attribute DOMString height;
  [CEReactions] attribute DOMString width;

  [CEReactions] attribute DOMString ch;
  [CEReactions] attribute DOMString chOff;
```

```
  [CEReactions] attribute boolean noWrap;
  [CEReactions] attribute DOMString vAlign;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
};
```

The **align**, **axis**, **height**, and **width** IDL attributes of the td[p484] and th[p486] elements must reflect[p101] the respective content attributes of the same name.

The **ch** IDL attribute of the td[p484] and th[p486] elements must reflect[p101] the elements' char[p1367] content attributes.

The **chOff** IDL attribute of the td[p484] and th[p486] elements must reflect[p101] the elements' charoff[p1367] content attributes.

The **noWrap** IDL attribute of the td[p484] and th[p486] elements must reflect[p101] the elements' nowrap[p1367] content attributes.

The **vAlign** IDL attribute of the td[p484] and th[p486] elements must reflect[p101] the elements' valign[p1367] content attributes.

The **bgColor** IDL attribute of the td[p484] and th[p486] elements must reflect[p101] the elements' bgcolor[p1367] content attributes.

IDL
```
partial interface HTMLTableRowElement {
  [CEReactions] attribute DOMString align;
  [CEReactions] attribute DOMString ch;
  [CEReactions] attribute DOMString chOff;
  [CEReactions] attribute DOMString vAlign;

  [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;
};
```

The **align** IDL attribute of the tr[p483] element must reflect[p101] the content attribute of the same name.

The **ch** IDL attribute of the tr[p483] element must reflect[p101] the element's char[p1367] content attribute.

The **chOff** IDL attribute of the tr[p483] element must reflect[p101] the element's charoff[p1367] content attribute.

The **vAlign** IDL attribute of the tr[p483] element must reflect[p101] the element's valign[p1367] content attribute.

The **bgColor** IDL attribute of the tr[p483] element must reflect[p101] the element's bgcolor[p1367] content attribute.

IDL
```
partial interface HTMLUListElement {
  [CEReactions] attribute boolean compact;
  [CEReactions] attribute DOMString type;
};
```

The **compact** and **type** IDL attributes of the ul[p234] element must reflect[p101] the respective content attributes of the same name.

User agents must treat xmp[p1363] elements in a manner equivalent to pre[p228] elements in terms of semantics and for purposes of rendering. (The parser has special behavior for this element though.)

IDL
```
partial interface Document {
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString fgColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString linkColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString vlinkColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString alinkColor;
  [CEReactions] attribute [LegacyNullToEmptyString] DOMString bgColor;

  [SameObject] readonly attribute HTMLCollection anchors;
```

```
  [SameObject] readonly attribute HTMLCollection applets;

  undefined clear();
  undefined captureEvents();
  undefined releaseEvents();

  [SameObject] readonly attribute HTMLAllCollection all;
};
```

The attributes of the Document[p127] object listed in the first column of the following table must reflect[p101] the content attribute on the body element[p133] with the name given in the corresponding cell in the second column on the same row, if the body element[p133] is a body[p199] element (as opposed to a frameset[p1369] element). When there is no body element[p133] or if it is a frameset[p1369] element, the attributes must instead return the empty string on getting and do nothing on setting.

IDL attribute	Content attribute
fgColor	text[p1366]
linkColor	link[p1366]
vlinkColor	vlink[p1366]
alinkColor	alink[p1366]
bgColor	bgcolor[p1366]

The **anchors** attribute must return an HTMLCollection rooted at the Document[p127] node, whose filter matches only a[p252] elements with name[p1363] attributes.

The **applets** attribute must return an HTMLCollection rooted at the Document[p127] node, whose filter matches nothing. (It exists for historical reasons.)

The **clear()**, **captureEvents()**, and **releaseEvents()** methods must do nothing.

The **all** attribute must return an HTMLAllCollection[p109] rooted at the Document[p127] node, whose filter matches all elements.

IDL
```
partial interface Window {
  undefined captureEvents();
  undefined releaseEvents();

  [Replaceable, SameObject] readonly attribute External external;
};
```

The **captureEvents()** and **releaseEvents()** methods must do nothing.

The **external** attribute of the Window[p892] interface must return an instance of the External[p1379] interface:

IDL
```
[Exposed=Window]
interface External {
  undefined AddSearchProvider();
  undefined IsSearchProviderInstalled();
};
```

The **AddSearchProvider()** and **IsSearchProviderInstalled()** methods must do nothing.

17 IANA considerations §[p1380]

17.1 text/html §[p1380]

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

text

Subtype name:

html

Required parameters:

No required parameters

Optional parameters:

charset

The `charset` parameter may be provided to specify the document's character encoding, overriding any character encoding declarations[p194] in the document other than a Byte Order Mark (BOM). The parameter's value must be an ASCII case-insensitive match for the string "`utf-8`". [ENCODING][p1413]

Encoding considerations:

8bit (see the section on character encoding declarations[p194])

Security considerations:

Entire novels have been written about the security considerations that apply to HTML documents. Many are listed in this document, to which the reader is referred for more details. Some general concerns bear mentioning here, however:

HTML is scripted language, and has a large number of APIs (some of which are described in this document). Script can expose the user to potential risks of information leakage, credential leakage, cross-site scripting attacks, cross-site request forgeries, and a host of other problems. While the designs in this specification are intended to be safe if implemented correctly, a full implementation is a massive undertaking and, as with any software, user agents are likely to have security bugs.

Even without scripting, there are specific features in HTML which, for historical reasons, are required for broad compatibility with legacy content but that expose the user to unfortunate security problems. In particular, the `img`[p338] element can be used in conjunction with some other features as a way to effect a port scan from the user's location on the Internet. This can expose local network topologies that the attacker would otherwise not be able to determine.

HTML relies on a compartmentalization scheme sometimes known as the *same-origin policy*. An origin[p869] in most cases consists of all the pages served from the same host, on the same port, using the same protocol.

It is critical, therefore, to ensure that any untrusted content that forms part of a site be hosted on a different origin[p869] than any sensitive content on that site. Untrusted content can easily spoof any other page on the same origin, read data from that origin, cause scripts in that origin to execute, submit forms to and from that origin even if they are protected from cross-site request forgery attacks by unique tokens, and make use of any third-party resources exposed to or rights granted to that origin.

Interoperability considerations:

Rules for processing both conforming and non-conforming content are defined in this specification.

Published specification:

This document is the relevant specification. Labeling a resource with the `text/html`[p1380] type asserts that the resource is an HTML document using the HTML syntax[p1198].

Applications that use this media type:

Web browsers, tools for processing web content, HTML authoring tools, search engines, validators.

Additional information:

Magic number(s):

No sequence of bytes can uniquely identify an HTML document. More information on detecting HTML documents is available in *MIME Sniffing*. [MIMESNIFF][p1414]

File extension(s):

"`html`" and "`htm`" are commonly, but certainly not exclusively, used as the extension for HTML documents.

Macintosh file type code(s):

TEXT

Person & email address to contact for further information:

Ian Hickson <ian@hixie.ch>

Intended usage:

Common

Restrictions on usage:

No restrictions apply.

Author:

Ian Hickson <ian@hixie.ch>

Change controller:

W3C

Fragments used with `text/html`[p1380] resources either refer to the indicated part[p1012] of the corresponding `Document`[p127], or provide state information for in-page scripts.

17.2 `multipart/x-mixed-replace` §[p1381]

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

multipart

Subtype name:

x-mixed-replace

Required parameters:

- `boundary` (defined in RFC2046) [RFC2046][p1416]

Optional parameters:

No optional parameters.

Encoding considerations:

binary

Security considerations:

Subresources of a `multipart/x-mixed-replace`[p1381] resource can be of any type, including types with non-trivial security implications such as `text/html`[p1380].

Interoperability considerations:

None.

Published specification:

This specification describes processing rules for web browsers. Conformance requirements for generating resources with this type are the same as for `multipart/mixed`[p1409]. [RFC2046][p1416]

Applications that use this media type:

This type is intended to be used in resources generated by web servers, for consumption by web browsers.

Additional information:

Magic number(s):

No sequence of bytes can uniquely identify a `multipart/x-mixed-replace`[p1381] resource.

File extension(s):

No specific file extensions are recommended for this type.

Macintosh file type code(s):

No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:

Ian Hickson <ian@hixie.ch>

Intended usage:

Common

Restrictions on usage:

No restrictions apply.

Author:

Ian Hickson <ian@hixie.ch>

Change controller:

W3C

Fragments used with `multipart/x-mixed-replace`[p1381] resources apply to each body part as defined by the type used by that body part.

17.3 `application/xhtml+xml` §[p1382]

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

application

Subtype name:

xhtml+xml

Required parameters:

Same as for `application/xml`[p1408] [RFC7303][p1416]

Optional parameters:

Same as for `application/xml`[p1408] [RFC7303][p1416]

Encoding considerations:

Same as for `application/xml`[p1408] [RFC7303][p1416]

Security considerations:

Same as for `application/xml`[p1408] [RFC7303][p1416]

Interoperability considerations:

Same as for `application/xml`[p1408] [RFC7303][p1416]

Published specification:

Labeling a resource with the `application/xhtml+xml`[p1382] type asserts that the resource is an XML document that likely has a document element from the HTML namespace. Thus, the relevant specifications are *XML*, *Namespaces in XML*, and this specification. [XML][p1419] [XMLNS][p1419]

Applications that use this media type:

Same as for `application/xml`[p1408] [RFC7303][p1416]

Additional information:

Magic number(s):

Same as for `application/xml`[p1408] [RFC7303][p1416]

File extension(s):

"`xhtml`" and "`xht`" are sometimes used as extensions for XML resources that have a document element from the HTML namespace.

Macintosh file type code(s):

TEXT

Person & email address to contact for further information:

Ian Hickson <ian@hixie.ch>

Intended usage:

Common

Restrictions on usage:

No restrictions apply.

Author:

Ian Hickson <ian@hixie.ch>

Change controller:

W3C

Fragments used with `application/xhtml+xml`[p1382] resources have the same semantics as with any XML MIME type. [RFC7303][p1416]

17.4 text/ping §[p1383]

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

text

Subtype name:

ping

Required parameters:

No parameters

Optional parameters:

`charset`

The `charset` parameter may be provided. The parameter's value must be "`utf-8`". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

Encoding considerations:

Not applicable.

Security considerations:

If used exclusively in the fashion described in the context of hyperlink auditing[p307], this type introduces no new security concerns.

Interoperability considerations:

Rules applicable to this type are defined in this specification.

Published specification:

This document is the relevant specification.

Applications that use this media type:

Web browsers.

Additional information:

Magic number(s):

`text/ping`[p1383] resources always consist of the four bytes 0x50 0x49 0x4E 0x47 (`PING`).

File extension(s):

No specific file extension is recommended for this type.

Macintosh file type code(s):

No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:

Ian Hickson <ian@hixie.ch>

Intended usage:

Common

Restrictions on usage:

Only intended for use with HTTP POST requests generated as part of a web browser's processing of the `ping`[p297] attribute.

Author:

Ian Hickson <ian@hixie.ch>

Change controller:

W3C

Fragments have no meaning with text/ping[p1383] resources.

17.5 application/microdata+json §[p1384]

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

application

Subtype name:

microdata+json

Required parameters:

Same as for application/json[p1408] [JSON][p1414]

Optional parameters:

Same as for application/json[p1408] [JSON][p1414]

Encoding considerations:

8bit (always UTF-8)

Security considerations:

Same as for application/json[p1408] [JSON][p1414]

Interoperability considerations:

Same as for application/json[p1408] [JSON][p1414]

Published specification:

Labeling a resource with the application/microdata+json[p1384] type asserts that the resource is a JSON text that consists of an object with a single entry called "items" consisting of an array of entries, each of which consists of an object with an entry called "id" whose value is a string, an entry called "type" whose value is another string, and an entry called "properties" whose value is an object whose entries each have a value consisting of an array of either objects or strings, the objects being of the same form as the objects in the aforementioned "items" entry. Thus, the relevant specifications are *JSON* and this specification. [JSON][p1414]

Applications that use this media type:

Applications that transfer data intended for use with HTML's microdata feature, especially in the context of drag-and-drop, are the primary application class for this type.

Additional information:

Magic number(s):

Same as for application/json[p1408] [JSON][p1414]

File extension(s):

Same as for application/json[p1408] [JSON][p1414]

Macintosh file type code(s):

Same as for application/json[p1408] [JSON][p1414]

Person & email address to contact for further information:

Ian Hickson <ian@hixie.ch>

Intended usage:

Common

Restrictions on usage:

No restrictions apply.

Author:

Ian Hickson <ian@hixie.ch>

Change controller:

W3C

Fragments used with application/microdata+json[p1384] resources have the same semantics as when used with application/json[p1408] (namely, at the time of writing, no semantics at all). [JSON][p1414]

17.6 text/event-stream §[p1385]

This registration is for community review and will be submitted to the IESG for review, approval, and registration with IANA.

Type name:

text

Subtype name:

event-stream

Required parameters:

No parameters

Optional parameters:

`charset`

The `charset` parameter may be provided. The parameter's value must be "`utf-8`". This parameter serves no purpose; it is only allowed for compatibility with legacy servers.

Encoding considerations:

8bit (always UTF-8)

Security considerations:

An event stream from an origin distinct from the origin of the content consuming the event stream can result in information leakage. To avoid this, user agents are required to apply CORS semantics. [FETCH][p1413]

Event streams can overwhelm a user agent; a user agent is expected to apply suitable restrictions to avoid depleting local resources because of an overabundance of information from an event stream.

Servers can be overwhelmed if a situation develops in which the server is causing clients to reconnect rapidly. Servers should use a 5xx status code to indicate capacity problems, as this will prevent conforming clients from reconnecting automatically.

Interoperability considerations:

Rules for processing both conforming and non-conforming content are defined in this specification.

Published specification:

This document is the relevant specification.

Applications that use this media type:

Web browsers and tools using web services.

Additional information:

Magic number(s):

No sequence of bytes can uniquely identify an event stream.

File extension(s):

No specific file extensions are recommended for this type.

Macintosh file type code(s):

No specific Macintosh file type codes are recommended for this type.

Person & email address to contact for further information:

Ian Hickson <ian@hixie.ch>

Intended usage:

Common

Restrictions on usage:

This format is only expected to be used by dynamic open-ended streams served using HTTP or a similar protocol. Finite resources are not expected to be labeled with this type.

Author:

Ian Hickson <ian@hixie.ch>

Change controller:

W3C

Fragments have no meaning with `text/event-stream`[p1385] resources.

17.7 web+ scheme prefix §[p1386]

This section describes a convention for use with the IANA URI scheme registry. It does not itself register a specific scheme. [RFC7595][p1416]

Scheme name:

Schemes starting with the four characters "`web+`" followed by one or more letters in the range `a-z`.

Status:

Permanent

Scheme syntax:

Scheme-specific.

Scheme semantics:

Scheme-specific.

Encoding considerations:

All "`web+`" schemes should use UTF-8 encodings where relevant.

Applications/protocols that use this scheme name:

Scheme-specific.

Interoperability considerations:

The scheme is expected to be used in the context of web applications.

Security considerations:

Any web page is able to register a handler for all "`web+`" schemes. As such, these schemes must not be used for features intended to be core platform features (e.g., HTTP). Similarly, such schemes must not store confidential information in their URLs, such as usernames, passwords, personal information, or confidential project names.

Contact:

Ian Hickson <ian@hixie.ch>

Change controller:

Ian Hickson <ian@hixie.ch>

autonomous custom elements[p742]	Author-defined elements	flow[p146]; phrasing[p146]; palpable[p147]	flow[p146]; phrasing[p146]	transparent[p148]	globals[p151]; any, as decided by the element's author	Supplied by the element's author (inherits from HTMLElement[p138])

An asterisk (*) in a cell indicates that the actual rules are more complicated than indicated in the table above.

† Categories in the "Parents" column refer to parents that list the given categories in their content model, not to elements that themselves are in those categories. For example, the a[p252] element's "Parents" column says "phrasing", so any element whose content model contains the "phrasing" category could be a parent of an a[p252] element. Since the "flow" category includes all the "phrasing" elements, that means the th[p486] element could be a parent to an a[p252] element.

Element content categories §[p1393]

This section is non-normative.

List of element content categories

Category	Elements	Elements with exceptions
Metadata content[p145]	base[p170]; link[p172]; meta[p184]; noscript[p654]; script[p638]; style[p195]; template[p656]; title[p169]	—

Script-supporting elements[p148]	script[p638]; template[p656]	—

Attributes §[p1394]

This section is non-normative.

List of attributes (excluding event handler content attributes)

Attribute	Element(s)	Description	Value
abbr	th[p487]	Alternative label to use for the header cell when referencing the cell in other contexts	Text[p143]*
accept	input[p535]	Hint for expected file type in file upload controls[p535]	Set of comma-separated tokens[p93]* consisting of valid MIME type strings with no parameters or audio/*, video/*, or image/*

Attribute	Element(s)	Description	Value
accept-charset	form[p506]	Character encodings to use for form submission[p617]	ASCII case-insensitive match for "UTF-8"
accesskey	HTML elements[p831]	Keyboard shortcut to activate or focus element	Ordered set of unique space-separated tokens[p93], none of which are identical to another, each consisting of one code point in length
action	form[p592]	URL to use for form submission[p617]	Valid non-empty URL potentially surrounded by spaces[p94]
allow	iframe[p389]	Permissions policy to be applied to the iframe[p383]'s contents	Serialized permissions policy
allowfullscreen	iframe[p390]	Whether to allow the iframe[p383]'s contents to use requestFullscreen()	Boolean attribute[p72]
alt	area[p463]; img[p340]; input[p538]	Replacement text for use when images are not available	Text[p143]*
as	link[p175]	Potential destination for a preload request (for rel[p173]="preload[p321]" and rel[p173]="modulepreload[p316]")	Potential destination, for rel[p173]="preload[p321]"; script-like destination, for rel[p173]="modulepreload[p316]"
async	script[p640]	Execute script when available, without blocking while fetching	Boolean attribute[p72]
autocapitalize	HTML elements[p838]	Recommended autocapitalization behavior (for supported input methods)	"on[p838]"; "off[p838]"; "none[p838]"; "sentences[p838]"; "words[p838]"; "characters[p838]"
autocomplete	form[p507]	Default setting for autofill feature for controls in the form	"on"; "off"
autocomplete	input[p594]; select[p594]; textarea[p594]	Hint for form autofill feature	Autofill field[p597] name and related tokens*
autofocus	HTML elements[p828]	Automatically focus the element when the page is loaded	Boolean attribute[p72]
autoplay	audio[p427]; video[p427]	Hint that the media resource[p407] can be started automatically when the page is loaded	Boolean attribute[p72]
blocking	link[p176]; script[p641]; style[p196]	Whether the element is potentially render-blocking[p101]	Unordered set of unique space-separated tokens[p93]*
charset	meta[p185]	Character encoding declaration[p194]	"utf-8"
checked	input[p516]	Whether the control is checked	Boolean attribute[p72]
cite	blockquote[p230]; del[p332]; ins[p332]; q[p261]	Link to the source of the quotation or more information about the edit	Valid URL potentially surrounded by spaces[p94]
class	HTML elements[p151]	Classes to which the element belongs	Set of space-separated tokens[p92]
color	link[p176]	Color to use when customizing a site's icon (for rel[p173]="mask-icon")	CSS <color>
cols	textarea[p572]	Maximum number of characters per line	Valid non-negative integer[p74] greater than zero
colspan	td[p488]; th[p488]	Number of columns that the cell is to span	Valid non-negative integer[p74] greater than zero
content	meta[p185]	Value of the element	Text[p143]*
contenteditable	HTML elements[p833]	Whether the element is editable	"true"; "plaintext-only"; "false"
controls	audio[p455]; video[p455]	Show user agent controls	Boolean attribute[p72]
coords	area[p464]	Coordinates for the shape to be created in an image map[p464]	Valid list of floating-point numbers[p77]*
crossorigin	audio[p408]; img[p340]; link[p174]; script[p641]; video[p408]	How the element handles crossorigin requests	"anonymous[p97]"; "use-credentials[p97]"
data	object[p395]	Address of the resource	Valid non-empty URL potentially surrounded by spaces[p94]
datetime	del[p332]; ins[p332]	Date and (optionally) time of the change	Valid date string with optional time[p90]
datetime	time[p274]	Machine-readable value	Valid month string[p79], valid date string[p80], valid yearless date string[p81], valid time string[p81], valid local date and time string[p83], valid time-zone offset string[p83], valid global date and time string[p85], valid week string[p86], valid non-negative integer[p74], or valid duration string[p87]
decoding	img[p340]	Decoding hint to use when processing this image for presentation	"sync[p359]"; "async[p359]"; "auto[p359]"
default	track[p405]	Enable the track if no other text track[p441] is more suitable	Boolean attribute[p72]
defer	script[p640]	Defer script execution	Boolean attribute[p72]

Attribute	Element(s)	Description	Value
dir	HTML elements[p156]	The text directionality[p157] of the element	"ltr[p156]"; "rtl[p156]"; "auto[p157]"
dir	bdo[p292]	The text directionality[p157] of the element	"ltr[p156]"; "rtl[p156]"
dirname	input[p590]; textarea[p590]	Name of form control to use for sending the element's directionality[p157] in form submission[p617]	Text[p143]*
disabled	button[p591]; input[p591]; optgroup[p566]; option[p568]; select[p591]; textarea[p591]; form-associated custom elements[p591]	Whether the form control is disabled	Boolean attribute[p72]
disabled	fieldset[p584]	Whether the descendant form controls, except any inside legend[p586], are disabled	Boolean attribute[p72]
disabled	link[p176]	Whether the link is disabled	Boolean attribute[p72]
download	a[p297]; area[p297]	Whether to download the resource instead of navigating to it, and its filename if so	Text
draggable	HTML elements[p856]	Whether the element is draggable	"true"; "false"
enctype	form[p593]	Entry list[p622] encoding type to use for form submission[p617]	"application/x-www-form-urlencoded[p593]"; "multipart/form-data[p593]"; "text/plain[p593]"
enterkeyhint	HTML elements[p840]	Hint for selecting an enter key action	"enter[p840]"; "done[p840]"; "go[p840]"; "next[p840]"; "previous[p840]"; "search[p840]"; "send[p840]"
fetchpriority	img[p340]; link[p176]; script[p641]	Sets the priority for fetches initiated by the element	"auto[p101]"; "high[p101]"; "low[p101]"
for	label[p510]	Associate the label with form control	ID*
for	output[p575]	Specifies controls from which the output was calculated	Unordered set of unique space-separated tokens[p93] consisting of IDs*
form	button[p588]; fieldset[p588]; input[p588]; object[p588]; output[p588]; select[p588]; textarea[p588]; form-associated custom elements[p588]	Associates the element with a form[p505] element	ID*
formaction	button[p592]; input[p592]	URL to use for form submission[p617]	Valid non-empty URL potentially surrounded by spaces[p94]
formenctype	button[p593]; input[p593]	Entry list[p622] encoding type to use for form submission[p617]	"application/x-www-form-urlencoded[p593]"; "multipart/form-data[p593]"; "text/plain[p593]"
formmethod	button[p592]; input[p592]	Variant to use for form submission[p617]	"GET"; "POST"; "dialog"
formnovalidate	button[p593]; input[p593]	Bypass form control validation for form submission[p617]	Boolean attribute[p72]
formtarget	button[p593]; input[p593]	Navigable[p952] for form submission[p617]	Valid navigable target name or keyword[p959]
headers	td[p488]; th[p488]	The header cells for this cell	Unordered set of unique space-separated tokens[p93] consisting of IDs*
height	canvas[p662]; embed[p468]; iframe[p468]; img[p468]; input[p468]; object[p468]; source[p468] (in picture[p334]); video[p468]	Vertical dimension	Valid non-negative integer[p74]
hidden	HTML elements[p805]	Whether the element is relevant	"until-found[p805]"; "hidden[p805]"; the empty string
high	meter[p580]	Low limit of high range	Valid floating-point number[p74]*
href	a[p297]; area[p297]	Address of the hyperlink[p297]	Valid URL potentially surrounded by spaces[p94]
href	link[p173]	Address of the hyperlink[p297]	Valid non-empty URL potentially surrounded by spaces[p94]
href	base[p171]	Document base URL[p94]	Valid URL potentially surrounded by spaces[p94]
hreflang	a[p298]; link[p174]	Language of the linked resource	Valid BCP 47 language tag
http-equiv	meta[p190]	Pragma directive	"content-type[p190]"; "default-style[p190]"; "refresh[p190]"; "x-ua-compatible[p190]"; "content-security-policy[p190]"
id	HTML elements[p151]	The element's ID	Text[p143]*
imagesizes	link[p175]	Image sizes for different page layouts (for rel[p173]="preload[p321]")	Valid source size list[p355]
imagesrcset	link[p174]	Images to use in different situations, e.g., high-resolution displays, small monitors, etc. (for	Comma-separated list of image candidate strings[p354]

Attribute	Element(s)	Description	Value
		rel[p173]="preload[p321]")	
inert	HTML elements[p809]	Whether the element is inert[p808].	Boolean attribute[p72]
inputmode	HTML elements[p839]	Hint for selecting an input modality	"none[p839]"; "text[p839]"; "tel[p839]"; "email[p839]"; "url[p839]"; "numeric[p839]"; "decimal[p839]"; "search[p839]"
integrity	link[p174]; script[p641]	Integrity metadata used in *Subresource Integrity* checks [SRI][p1417]	Text[p143]
is	HTML elements[p742]	Creates a customized built-in element[p742]	Valid custom element name[p743] of a defined customized built-in element[p742]
ismap	img[p342]	Whether the image is a server-side image map	Boolean attribute[p72]
itemid	HTML elements[p775]	Global identifier[p775] for a microdata item	Valid URL potentially surrounded by spaces[p94]
itemprop	HTML elements[p776]	Property names[p777] of a microdata item	Unordered set of unique space-separated tokens[p93] consisting of valid absolute URLs, defined property names[p777], or text*
itemref	HTML elements[p775]	Referenced[p138] elements	Unordered set of unique space-separated tokens[p93] consisting of IDs*
itemscope	HTML elements[p774]	Introduces a microdata item	Boolean attribute[p72]
itemtype	HTML elements[p774]	Item types[p774] of a microdata item	Unordered set of unique space-separated tokens[p93] consisting of valid absolute URLs*
kind	track[p404]	The type of text track	"subtitles[p404]"; "captions[p404]"; "descriptions[p404]"; "chapters[p404]"; "metadata[p404]"
label	optgroup[p566]; option[p568]; track[p405]	User-visible label	Text[p143]
lang	HTML elements[p154]	Language[p155] of the element	Valid BCP 47 language tag or the empty string
list	input[p548]	List of autocomplete options	ID*
loading	iframe[p390]; img[p340]	Used when determining loading deferral	"lazy[p99]"; "eager[p99]"
loop	audio[p424]; video[p424]	Whether to loop the media resource[p407]	Boolean attribute[p72]
low	meter[p580]	High limit of low range	Valid floating-point number[p74]*
max	input[p546]	Maximum value	Varies*
max	meter[p580]; progress[p577]	Upper bound of range	Valid floating-point number[p74]*
maxlength	input[p541]; textarea[p572]	Maximum length of value	Valid non-negative integer[p74]
media	link[p174]; meta[p185]; source[p336]; style[p196]	Applicable media	Valid media query list[p93]
method	form[p592]	Variant to use for form submission[p617]	"GET[p592]"; "POST[p592]"; "dialog[p592]"
min	input[p546]	Minimum value	Varies*
min	meter[p580]	Lower bound of range	Valid floating-point number[p74]*
minlength	input[p541]; textarea[p573]	Minimum length of value	Valid non-negative integer[p74]
multiple	input[p544]; select[p560]	Whether to allow multiple values	Boolean attribute[p72]
muted	audio[p457]; video[p457]	Whether to mute the media resource[p407] by default	Boolean attribute[p72]
name	button[p589]; fieldset[p589]; input[p589]; output[p589]; select[p589]; textarea[p589]; form-associated custom elements[p589]	Name of the element to use for form submission[p617] and in the form.elements[p507] API	Text[p143]*
name	form[p506]	Name of form to use in the document.forms[p134] API	Text[p143]*
name	iframe[p387]; object[p395]	Name of content navigable[p955]	Valid navigable target name or keyword[p959]
name	map[p462]	Name of image map[p464] to reference[p138] from the usemap[p465] attribute	Text[p143]*
name	meta[p185]	Metadata name	Text[p143]*
name	slot[p660]	Name of shadow tree slot	Text[p143]
nomodule	script[p640]	Prevents execution in user agents that support module scripts[p1040]	Boolean attribute[p72]
nonce	HTML elements[p98]	Cryptographic nonce used in *Content Security Policy* checks [CSP][p1411]	Text[p143]
novalidate	form[p593]	Bypass form control validation for	Boolean attribute[p72]

Attribute	Element(s)	Description	Value
		form submission[p617]	
open	details[p627]	Whether the details are visible	Boolean attribute[p72]
open	dialog[p635]	Whether the dialog box is showing	Boolean attribute[p72]
optimum	meter[p580]	Optimum value in gauge	Valid floating-point number[p74]*
pattern	input[p544]	Pattern to be matched by the form control's value	Regular expression matching the JavaScript *Pattern* production
ping	a[p297]; area[p297]	URLs to ping	Set of space-separated tokens[p92] consisting of valid non-empty URLs[p94]
placeholder	input[p550]; textarea[p573]	User-visible label to be placed within the form control	Text[p143]*
playsinline	video[p399]	Encourage the user agent to display video content within the element's playback area	Boolean attribute[p72]
popover	HTML elements[p857]	Makes the element a popover[p857] element	"auto[p859]"; "manual[p859]";
popovertarget	input[p865]; button[p865]	Targets a popover element to toggle, show, or hide	ID*
popovertargetaction	input[p865]; button[p865]	Indicates whether a targeted popover element is to be toggled, shown, or hidden	"toggle[p865]"; "show[p865]"; "hide[p865]"
poster	video[p399]	Poster frame to show prior to video playback	Valid non-empty URL potentially surrounded by spaces[p94]
preload	audio[p421]; video[p421]	Hints how much buffering the media resource[p407] will likely need	"none[p421]"; "metadata[p421]"; "auto[p421]"
readonly	input[p542]; textarea[p571]	Whether to allow the value to be edited by the user	Boolean attribute[p72]
readonly	form-associated custom elements[p743]	Affects willValidate[p615], plus any behavior added by the custom element author	Boolean attribute[p72]
referrerpolicy	a[p298]; area[p298]; iframe[p390]; img[p340]; link[p174]; script[p641]	Referrer policy for fetches initiated by the element	Referrer policy
rel	a[p297]; area[p297]	Relationship between the location in the document containing the hyperlink[p297] and the destination resource	Unordered set of unique space-separated tokens[p93]*
rel	link[p173]	Relationship between the document containing the hyperlink[p297] and the destination resource	Unordered set of unique space-separated tokens[p93]*
required	input[p543]; select[p560]; textarea[p573]	Whether the control is required for form submission[p617]	Boolean attribute[p72]
reversed	ol[p233]	Number the list backwards	Boolean attribute[p72]
rows	textarea[p572]	Number of lines to show	Valid non-negative integer[p74] greater than zero
rowspan	td[p488]; th[p488]	Number of rows that the cell is to span	Valid non-negative integer[p74]
sandbox	iframe[p388]	Security rules for nested content	Unordered set of unique space-separated tokens[p93], ASCII case-insensitive, consisting of • "allow-downloads[p887]" • "allow-forms[p886]" • "allow-modals[p887]" • "allow-orientation-lock[p887]" • "allow-pointer-lock[p886]" • "allow-popups[p886]" • "allow-popups-to-escape-sandbox[p887]" • "allow-presentation[p887]" • "allow-same-origin[p886]" • "allow-scripts[p886]" • "allow-top-navigation[p886]" • "allow-top-navigation-by-user-activation[p886]" • "allow-top-navigation-to-custom-protocols[p887]"
scope	th[p486]	Specifies which cells the header cell applies to	"row[p486]"; "col[p486]"; "rowgroup[p486]"; "colgroup[p487]"
selected	option[p568]	Whether the option is selected by default	Boolean attribute[p72]
shape	area[p464]	The kind of shape to be created in an image map[p464]	"circle[p464]"; "default[p464]"; "poly[p464]"; "rect[p464]"

Attribute	Element(s)	Description	Value
size	input[p542]; select[p560]	Size of the control	Valid non-negative integer[p74] greater than zero
sizes	link[p175]	Sizes of the icons (for rel[p173]="icon[p313]")	Unordered set of unique space-separated tokens[p93], ASCII case-insensitive, consisting of sizes*
sizes	img[p340]; source[p336]	Image sizes for different page layouts	Valid source size list[p355]
slot	HTML elements[p151]	The element's desired slot	Text[p143]
span	col[p479]; colgroup[p479]	Number of columns spanned by the element	Valid non-negative integer[p74] greater than zero
spellcheck	HTML elements[p836]	Whether the element is to have its spelling and grammar checked	"true"; "false"
src	audio[p408]; embed[p392]; iframe[p384]; img[p340]; input[p538]; script[p640]; source[p337] (in video[p398] or audio[p402]); track[p404]; video[p408]	Address of the resource	Valid non-empty URL potentially surrounded by spaces[p94]
srcdoc	iframe[p384]	A document to render in the iframe[p383]	The source of an iframe srcdoc document[p384]*
srclang	track[p404]	Language of the text track	Valid BCP 47 language tag
srcset	img[p340]; source[p336]	Images to use in different situations, e.g., high-resolution displays, small monitors, etc.	Comma-separated list of image candidate strings[p354]
start	ol[p233]	Starting value[p233] of the list	Valid integer[p74]
step	input[p547]	Granularity to be matched by the form control's value	Valid floating-point number[p74] greater than zero, or "any"
style	HTML elements[p159]	Presentational and formatting instructions	CSS declarations*
tabindex	HTML elements[p819]	Whether the element is focusable[p817] and sequentially focusable[p817], and the relative order of the element for the purposes of sequential focus navigation[p825]	Valid integer[p74]
target	a[p297]; area[p297]	Navigable[p952] for hyperlink[p297] navigation[p977]	Valid navigable target name or keyword[p959]
target	base[p171]	Default navigable[p952] for hyperlink[p297] navigation[p977] and form submission[p617]	Valid navigable target name or keyword[p959]
target	form[p593]	Navigable[p952] for form submission[p617]	Valid navigable target name or keyword[p959]
title	HTML elements[p154]	Advisory information for the element	Text[p143]
title	abbr[p264]; dfn[p263]	Full term or expansion of abbreviation	Text[p143]
title	input[p545]	Description of pattern (when used with pattern[p544] attribute)	Text[p143]
title	link[p174]	Title of the link	Text[p143]
title	link[p174]; style[p196]	CSS style sheet set name	Text[p143]
translate	HTML elements[p155]	Whether the element is to be translated when the page is localized	"yes"; "no"
type	a[p298]; link[p174]	Hint for the type of the referenced resource	Valid MIME type string
type	button[p557]	Type of button	"submit[p557]"; "reset[p557]"; "button[p557]"
type	embed[p392]; object[p395]; source[p336]	Type of embedded resource	Valid MIME type string
type	input[p514]	Type of form control	input type keyword[p514]
type	ol[p233]	Kind of list marker	"1[p233]"; "a[p233]"; "A[p233]"; "i[p233]"; "I[p233]"
type	script[p639]	Type of script	"module"; a valid MIME type string that is not a JavaScript MIME type essence match
usemap	img[p465]	Name of image map[p464] to use	Valid hash-name reference[p93]*
value	button[p558]; option[p568]	Value to be used for form submission[p617]	Text[p143]
value	data[p273]	Machine-readable value	Text[p143]*
value	input[p516]	Value of the form control	Varies*
value	li[p236]	Ordinal value[p237] of the list item	Valid integer[p74]
value	meter[p580]; progress[p577]	Current value of the element	Valid floating-point number[p74]
width	canvas[p662]; embed[p468];	Horizontal dimension	Valid non-negative integer[p74]

Attribute	Element(s)	Description	Value
	iframe[p468]; img[p468]; input[p468]; object[p468]; source[p468] (in picture[p334]); video[p468]		
wrap	textarea[p572]	How the value of the form control is to be wrapped for form submission[p617]	"soft[p572]"; "hard[p572]"

An asterisk (*) in a cell indicates that the actual rules are more complicated than indicated in the table above.

List of event handler content attributes

Attribute	Element(s)	Description	Value
onauxclick	HTML elements[p1090]	auxclick event handler	Event handler content attribute[p1084]
onafterprint	body[p1092]	afterprint[p1406] event handler for Window[p892] object	Event handler content attribute[p1084]
onbeforematch	HTML elements[p1090]	beforematch[p1406] event handler	Event handler content attribute[p1084]
onbeforeprint	body[p1092]	beforeprint[p1406] event handler for Window[p892] object	Event handler content attribute[p1084]
onbeforeunload	body[p1092]	beforeunload[p1406] event handler for Window[p892] object	Event handler content attribute[p1084]
onbeforetoggle	HTML elements[p1090]	beforetoggle[p1406] event handler	Event handler content attribute[p1084]
onblur	HTML elements[p1091]	blur[p1406] event handler	Event handler content attribute[p1084]
oncancel	HTML elements[p1090]	cancel[p1406] event handler	Event handler content attribute[p1084]
oncanplay	HTML elements[p1090]	canplay[p459] event handler	Event handler content attribute[p1084]
oncanplaythrough	HTML elements[p1090]	canplaythrough[p459] event handler	Event handler content attribute[p1084]
onchange	HTML elements[p1090]	change[p1406] event handler	Event handler content attribute[p1084]
onclick	HTML elements[p1090]	click event handler	Event handler content attribute[p1084]
onclose	HTML elements[p1090]	close[p1406] event handler	Event handler content attribute[p1084]
oncontextlost	HTML elements[p1090]	contextlost[p1406] event handler	Event handler content attribute[p1084]
oncontextmenu	HTML elements[p1090]	contextmenu event handler	Event handler content attribute[p1084]
oncontextrestored	HTML elements[p1090]	contextrestored[p1406] event handler	Event handler content attribute[p1084]
oncopy	HTML elements[p1090]	copy event handler	Event handler content attribute[p1084]
oncuechange	HTML elements[p1090]	cuechange[p460] event handler	Event handler content attribute[p1084]
oncut	HTML elements[p1090]	cut event handler	Event handler content attribute[p1084]
ondblclick	HTML elements[p1090]	dblclick event handler	Event handler content attribute[p1084]
ondrag	HTML elements[p1090]	drag[p856] event handler	Event handler content attribute[p1084]
ondragend	HTML elements[p1090]	dragend[p856] event handler	Event handler content attribute[p1084]
ondragenter	HTML elements[p1090]	dragenter[p856] event handler	Event handler content attribute[p1084]
ondragleave	HTML elements[p1090]	dragleave[p856] event handler	Event handler content attribute[p1084]
ondragover	HTML elements[p1090]	dragover[p856] event handler	Event handler content attribute[p1084]
ondragstart	HTML elements[p1090]	dragstart[p856] event handler	Event handler content attribute[p1084]
ondrop	HTML elements[p1090]	drop[p856] event handler	Event handler content attribute[p1084]
ondurationchange	HTML elements[p1090]	durationchange[p459] event handler	Event handler content attribute[p1084]
onemptied	HTML elements[p1090]	emptied[p458] event handler	Event handler content attribute[p1084]
onended	HTML elements[p1090]	ended[p459] event handler	Event handler content attribute[p1084]
onerror	HTML elements[p1091]	error[p1406] event handler	Event handler content attribute[p1084]
onfocus	HTML elements[p1091]	focus[p1406] event handler	Event handler content attribute[p1084]
onformdata	HTML elements[p1090]	formdata[p1406] event handler	Event handler content attribute[p1084]
onhashchange	body[p1092]	hashchange[p1406] event handler for Window[p892] object	Event handler content attribute[p1084]
oninput	HTML elements[p1090]	input event handler	Event handler content attribute[p1084]
oninvalid	HTML elements[p1090]	invalid[p1407] event handler	Event handler content attribute[p1084]
onkeydown	HTML elements[p1090]	keydown event handler	Event handler content attribute[p1084]
onkeypress	HTML elements[p1091]	keypress event handler	Event handler content attribute[p1084]
onkeyup	HTML elements[p1091]	keyup event handler	Event handler content attribute[p1084]
onlanguagechange	body[p1092]	languagechange[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]
onload	HTML elements[p1091]	load[p1407] event handler	Event handler content attribute[p1084]
onloadeddata	HTML elements[p1091]	loadeddata[p459] event handler	Event handler content attribute[p1084]
onloadedmetadata	HTML elements[p1091]	loadedmetadata[p459] event handler	Event handler content attribute[p1084]
onloadstart	HTML elements[p1091]	loadstart[p458] event handler	Event handler content attribute[p1084]
onmessage	body[p1092]	message[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]

Attribute	Element(s)	Description	Value
onmessageerror	body[p1092]	messageerror[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]
onmousedown	HTML elements[p1091]	mousedown event handler	Event handler content attribute[p1084]
onmouseenter	HTML elements[p1091]	mouseenter event handler	Event handler content attribute[p1084]
onmouseleave	HTML elements[p1091]	mouseleave event handler	Event handler content attribute[p1084]
onmousemove	HTML elements[p1091]	mousemove event handler	Event handler content attribute[p1084]
onmouseout	HTML elements[p1091]	mouseout event handler	Event handler content attribute[p1084]
onmouseover	HTML elements[p1091]	mouseover event handler	Event handler content attribute[p1084]
onmouseup	HTML elements[p1091]	mouseup event handler	Event handler content attribute[p1084]
onoffline	body[p1092]	offline[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]
ononline	body[p1092]	online[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]
onpagehide	body[p1092]	pagehide[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]
onpageshow	body[p1092]	pageshow[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]
onpaste	HTML elements[p1091]	paste event handler	Event handler content attribute[p1084]
onpause	HTML elements[p1091]	pause[p459] event handler	Event handler content attribute[p1084]
onplay	HTML elements[p1091]	play[p459] event handler	Event handler content attribute[p1084]
onplaying	HTML elements[p1091]	playing[p459] event handler	Event handler content attribute[p1084]
onpopstate	body[p1092]	popstate[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]
onprogress	HTML elements[p1091]	progress[p458] event handler	Event handler content attribute[p1084]
onratechange	HTML elements[p1091]	ratechange[p459] event handler	Event handler content attribute[p1084]
onreset	HTML elements[p1091]	reset[p1407] event handler	Event handler content attribute[p1084]
onresize	HTML elements[p1091]	resize event handler	Event handler content attribute[p1084]
onrejectionhandled	body[p1092]	rejectionhandled[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]
onscroll	HTML elements[p1091]	scroll event handler	Event handler content attribute[p1084]
onscrollend	HTML elements[p1091]	scrollend event handler	Event handler content attribute[p1084]
onsecuritypolicyviolation	HTML elements[p1091]	securitypolicyviolation event handler	Event handler content attribute[p1084]
onseeked	HTML elements[p1091]	seeked[p459] event handler	Event handler content attribute[p1084]
onseeking	HTML elements[p1091]	seeking[p459] event handler	Event handler content attribute[p1084]
onselect	HTML elements[p1091]	select[p1407] event handler	Event handler content attribute[p1084]
onslotchange	HTML elements[p1091]	slotchange event handler	Event handler content attribute[p1084]
onstalled	HTML elements[p1091]	stalled[p459] event handler	Event handler content attribute[p1084]
onstorage	body[p1092]	storage[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]
onsubmit	HTML elements[p1091]	submit[p1407] event handler	Event handler content attribute[p1084]
onsuspend	HTML elements[p1091]	suspend[p458] event handler	Event handler content attribute[p1084]
ontimeupdate	HTML elements[p1091]	timeupdate[p459] event handler	Event handler content attribute[p1084]
ontoggle	HTML elements[p1091]	toggle[p1407] event handler	Event handler content attribute[p1084]
onunhandledrejection	body[p1092]	unhandledrejection[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]
onunload	body[p1092]	unload[p1407] event handler for Window[p892] object	Event handler content attribute[p1084]
onvolumechange	HTML elements[p1091]	volumechange[p459] event handler	Event handler content attribute[p1084]
onwaiting	HTML elements[p1091]	waiting[p459] event handler	Event handler content attribute[p1084]
onwheel	HTML elements[p1091]	wheel event handler	Event handler content attribute[p1084]

Element interfaces §[p1401]

This section is non-normative.

List of interfaces for elements

Element(s)	Interface(s)
a[p252]	HTMLAnchorElement[p253] : HTMLElement[p138]
abbr[p263]	HTMLElement[p138]
address[p217]	HTMLElement[p138]
area[p463]	HTMLAreaElement[p463] : HTMLElement[p138]
article[p201]	HTMLElement[p138]
aside[p209]	HTMLElement[p138]

Element(s)	Interface(s)
audio[p402]	HTMLAudioElement[p403] : HTMLMediaElement[p406] : HTMLElement[p138]
b[p287]	HTMLElement[p138]
base[p170]	HTMLBaseElement[p170] : HTMLElement[p138]
bdi[p291]	HTMLElement[p138]
bdo[p292]	HTMLElement[p138]
blockquote[p229]	HTMLQuoteElement[p230] : HTMLElement[p138]
body[p199]	HTMLBodyElement[p200] : HTMLElement[p138]
br[p294]	HTMLBRElement[p294] : HTMLElement[p138]
button[p556]	HTMLButtonElement[p557] : HTMLElement[p138]
canvas[p661]	HTMLCanvasElement[p661] : HTMLElement[p138]
caption[p477]	HTMLTableCaptionElement[p477] : HTMLElement[p138]
cite[p259]	HTMLElement[p138]
code[p281]	HTMLElement[p138]
col[p479]	HTMLTableColElement[p479] : HTMLElement[p138]
colgroup[p478]	HTMLTableColElement[p479] : HTMLElement[p138]
data[p273]	HTMLDataElement[p273] : HTMLElement[p138]
datalist[p564]	HTMLDataListElement[p565] : HTMLElement[p138]
dd[p243]	HTMLElement[p138]
del[p331]	HTMLModElement[p332] : HTMLElement[p138]
details[p627]	HTMLDetailsElement[p627] : HTMLElement[p138]
dfn[p262]	HTMLElement[p138]
dialog[p633]	HTMLDialogElement[p634] : HTMLElement[p138]
div[p251]	HTMLDivElement[p251] : HTMLElement[p138]
dl[p238]	HTMLDListElement[p239] : HTMLElement[p138]
dt[p242]	HTMLElement[p138]
em[p255]	HTMLElement[p138]
embed[p391]	HTMLEmbedElement[p392] : HTMLElement[p138]
fieldset[p584]	HTMLFieldSetElement[p584] : HTMLElement[p138]
figcaption[p247]	HTMLElement[p138]
figure[p244]	HTMLElement[p138]
footer[p214]	HTMLElement[p138]
form[p505]	HTMLFormElement[p506] : HTMLElement[p138]
h1[p211]	HTMLHeadingElement[p211] : HTMLElement[p138]
h2[p211]	HTMLHeadingElement[p211] : HTMLElement[p138]
h3[p211]	HTMLHeadingElement[p211] : HTMLElement[p138]
h4[p211]	HTMLHeadingElement[p211] : HTMLElement[p138]
h5[p211]	HTMLHeadingElement[p211] : HTMLElement[p138]
h6[p211]	HTMLHeadingElement[p211] : HTMLElement[p138]
head[p168]	HTMLHeadElement[p168] : HTMLElement[p138]
header[p213]	HTMLElement[p138]
hgroup[p212]	HTMLElement[p138]
hr[p226]	HTMLHRElement[p226] : HTMLElement[p138]
html[p167]	HTMLHtmlElement[p167] : HTMLElement[p138]
i[p286]	HTMLElement[p138]
iframe[p383]	HTMLIFrameElement[p383] : HTMLElement[p138]
img[p338]	HTMLImageElement[p339] : HTMLElement[p138]
input[p512]	HTMLInputElement[p513] : HTMLElement[p138]
ins[p329]	HTMLModElement[p332] : HTMLElement[p138]
kbd[p284]	HTMLElement[p138]
label[p509]	HTMLLabelElement[p510] : HTMLElement[p138]
legend[p586]	HTMLLegendElement[p587] : HTMLElement[p138]
li[p236]	HTMLLIElement[p236] : HTMLElement[p138]
link[p172]	HTMLLinkElement[p173] : HTMLElement[p138]
main[p247]	HTMLElement[p138]

Element(s)	Interface(s)
map[p461]	HTMLMapElement[p462] : HTMLElement[p138]
mark[p289]	HTMLElement[p138]
menu[p235]	HTMLMenuElement[p235] : HTMLElement[p138]
meta[p184]	HTMLMetaElement[p184] : HTMLElement[p138]
meter[p579]	HTMLMeterElement[p579] : HTMLElement[p138]
nav[p206]	HTMLElement[p138]
noscript[p654]	HTMLElement[p138]
object[p394]	HTMLObjectElement[p394] : HTMLElement[p138]
ol[p232]	HTMLOListElement[p233] : HTMLElement[p138]
optgroup[p566]	HTMLOptGroupElement[p566] : HTMLElement[p138]
option[p567]	HTMLOptionElement[p567] : HTMLElement[p138]
output[p575]	HTMLOutputElement[p575] : HTMLElement[p138]
p[p223]	HTMLParagraphElement[p224] : HTMLElement[p138]
picture[p334]	HTMLPictureElement[p335] : HTMLElement[p138]
pre[p228]	HTMLPreElement[p228] : HTMLElement[p138]
progress[p577]	HTMLProgressElement[p577] : HTMLElement[p138]
q[p261]	HTMLQuoteElement[p230] : HTMLElement[p138]
rp[p272]	HTMLElement[p138]
rt[p271]	HTMLElement[p138]
ruby[p265]	HTMLElement[p138]
s[p259]	HTMLElement[p138]
samp[p283]	HTMLElement[p138]
search[p249]	HTMLElement[p138]
script[p638]	HTMLScriptElement[p639] : HTMLElement[p138]
section[p203]	HTMLElement[p138]
select[p559]	HTMLSelectElement[p559] : HTMLElement[p138]
slot[p659]	HTMLSlotElement[p660] : HTMLElement[p138]
small[p257]	HTMLElement[p138]
source[p335]	HTMLSourceElement[p336] : HTMLElement[p138]
span[p293]	HTMLSpanElement[p293] : HTMLElement[p138]
strong[p256]	HTMLElement[p138]
style[p195]	HTMLStyleElement[p195] : HTMLElement[p138]
sub[p285]	HTMLElement[p138]
summary[p630]	HTMLElement[p138]
sup[p285]	HTMLElement[p138]
table[p469]	HTMLTableElement[p469] : HTMLElement[p138]
tbody[p480]	HTMLTableSectionElement[p480] : HTMLElement[p138]
td[p484]	HTMLTableCellElement[p485] : HTMLElement[p138]
template[p656]	HTMLTemplateElement[p657] : HTMLElement[p138]
textarea[p570]	HTMLTextAreaElement[p570] : HTMLElement[p138]
tfoot[p482]	HTMLTableSectionElement[p480] : HTMLElement[p138]
th[p486]	HTMLTableCellElement[p485] : HTMLElement[p138]
thead[p481]	HTMLTableSectionElement[p480] : HTMLElement[p138]
time[p274]	HTMLTimeElement[p274] : HTMLElement[p138]
title[p169]	HTMLTitleElement[p169] : HTMLElement[p138]
tr[p483]	HTMLTableRowElement[p483] : HTMLElement[p138]
track[p403]	HTMLTrackElement[p404] : HTMLElement[p138]
u[p288]	HTMLElement[p138]
ul[p234]	HTMLUListElement[p234] : HTMLElement[p138]
var[p282]	HTMLElement[p138]
video[p398]	HTMLVideoElement[p399] : HTMLMediaElement[p406] : HTMLElement[p138]
wbr[p295]	HTMLElement[p138]
custom elements[p742]	supplied by the element's author (inherits from HTMLElement[p138])

Events §[p1406]

This section is non-normative.

The following table lists events fired by this document, excluding those already defined in media element events[p458] and drag-and-drop events[p856].

List of events

Event	Interface	Interesting targets	Description
DOMContentLoaded	Event	Document[p127]	Fired at the Document[p127] once the parser has finished
afterprint	Event	Window[p892]	Fired at the Window[p892] after printing
beforeprint	Event	Window[p892]	Fired at the Window[p892] before printing
beforematch	Event	Elements	Fired on elements with the hidden=until-found[p805] attribute before they are revealed.
beforetoggle	ToggleEvent[p868]	Elements	Fired on elements with the popover[p857] attribute when they are transitioning between showing and hidden
beforeunload	BeforeUnloadEvent[p951]	Window[p892]	Fired at the Window[p892] when the page is about to be unloaded, in case the page would like to show a warning prompt
blur	Event	Window[p892], elements	Fired at nodes when they stop being focused[p817]
cancel	Event	dialog[p633] elements, input[p512] elements	Fired at dialog[p633] elements when they are canceled by the user (e.g., by pressing the Escape key), or at input[p512] elements in the File[p535] state when the user does not change their selection
change	Event	Form controls	Fired at controls when the user commits a value change (see also the input event)
click	PointerEvent	Elements	Normally a mouse event; also synthetically fired at an element before its activation behavior is run, when an element is activated from a non-pointer input device (e.g. a keyboard)
close	Event	dialog[p633] elements	Fired at dialog[p633] elements when they are closed
connect	MessageEvent[p1128]	SharedWorkerGlobalScope[p1168]	Fired at a shared worker's global scope when a new client connects
contextlost	Event	canvas[p661] elements, OffscreenCanvas[p725] objects	Fired when the corresponding CanvasRenderingContext2D[p666] or OffscreenCanvasRenderingContext2D[p729] is lost
contextrestored	Event	canvas[p661] elements, OffscreenCanvas[p725] objects	Fired when the corresponding CanvasRenderingContext2D[p666] or OffscreenCanvasRenderingContext2D[p729] is restored after being lost
currententrychange	NavigationCurrentEntryChangeEvent[p949]	Navigation[p922]	Fired when navigation.currentEntry[p928] changes
dispose	Event	NavigationHistoryEntry[p926]	Fired when the session history entry[p968] corresponding to the NavigationHistoryEntry[p926] has been permanently evicted from session history and can no longer be traversed to
error	Event or ErrorEvent[p1054]	Global scope objects, Worker[p1174] objects, elements, networking-related objects	Fired when unexpected errors occur (e.g. networking errors, script errors, decoding errors)
focus	Event	Window[p892], elements	Fired at nodes gaining focus[p817]
formdata	FormDataEvent[p626]	form[p505] elements	Fired at a form[p505] element when it is constructing the entry list[p622]
hashchange	HashChangeEvent[p950]	Window[p892]	Fired at the Window[p892] when the fragment part of the document's URL changes
input	Event	Elements	Fired when the user changes the contenteditable[p833] element's content, or the form control's value. See also the change[p1406] event for form controls.

Event	Interface	Interesting targets	Description
invalid	Event	Form controls	Fired at controls during form validation if they do not satisfy their constraints
languagechange	Event	Global scope objects	Fired at the global scope object when the user's preferred languages change
load	Event	Window[p892], elements	Fired at the Window[p892] when the document has finished loading; fired at an element containing a resource (e.g. img[p338], embed[p391]) when its resource has finished loading
message	MessageEvent[p1128]	Window[p892], EventSource[p1130], MessagePort[p1144], BroadcastChannel[p1147], DedicatedWorkerGlobalScope[p1168], Worker[p1174], ServiceWorkerContainer	Fired at an object when it receives a message
messageerror	MessageEvent[p1128]	Window[p892], MessagePort[p1144], BroadcastChannel[p1147], DedicatedWorkerGlobalScope[p1168], Worker[p1174], ServiceWorkerContainer	Fired at an object when it receives a message that cannot be deserialized
navigate	NavigateEvent[p939]	Navigation[p922]	Fired before the navigable[p952] navigates[p977], reloads[p990], traverses[p990], or otherwise[p917] changes its URL
navigateerror	ErrorEvent[p1054]	Navigation[p922]	Fired when a navigation does not complete successfully
navigatesuccess	Event	Navigation[p922]	Fired when a navigation completes successfully
offline	Event	Global scope objects	Fired at the global scope object when the network connections fails
online	Event	Global scope objects	Fired at the global scope object when the network connections returns
open	Event	EventSource[p1130]	Fired at EventSource[p1130] objects when a connection is established
pagehide	PageTransitionEvent[p950]	Window[p892]	Fired at the Window[p892] when the page's session history entry[p968] stops being the active entry[p952]
pageshow	PageTransitionEvent[p950]	Window[p892]	Fired at the Window[p892] when the page's session history entry[p968] becomes the active entry[p952]
pointercancel	PointerEvent	Elements and Text nodes	Fired at the source node[p851] when the user attempts to initiate a drag-and-drop operation
popstate	PopStateEvent[p949]	Window[p892]	Fired at the Window[p892] when in some cases of session history traversal[p990]
readystatechange	Event	Document[p127]	Fired at the Document[p127] when it finishes parsing and again when all its subresources have finished loading
rejectionhandled	PromiseRejectionEvent[p1055]	Global scope objects	Fired at global scope objects when a previously-unhandled promise rejection becomes handled
reset	Event	form[p505] elements	Fired at a form[p505] element when it is reset[p626]
select	Event	Form controls	Fired at form controls when their text selection is adjusted (whether by an API or by the user)
storage	StorageEvent[p1194]	Window[p892]	Fired at Window[p892] event when the corresponding localStorage[p1194] or sessionStorage[p1193] storage areas change
submit	SubmitEvent[p625]	form[p505] elements	Fired at a form[p505] element when it is submitted[p619]
toggle	Event or ToggleEvent[p868]	details[p627] and popover[p857] elements	Fired at details[p627] elements when they open or close; fired on elements with the popover[p857] attribute when they are transitioning between showing and hidden
unhandledrejection	PromiseRejectionEvent[p1055]	Global scope objects	Fired at global scope objects when a promise rejection goes unhandled
unload	Event	Window[p892]	Fired at the Window[p892] object when the page is going away
visibilitychange	Event	Document[p127]	Fired at the Document[p127] object when the page becomes visible or hidden to the user

HTTP headers §[p1408]

This section is non-normative.

The following HTTP request headers are defined by this specification:

- `Last-Event-ID[p1133]`
- `Ping-From[p308]`
- `Ping-To[p308]`

The following HTTP response headers are defined by this specification:

- `Cross-Origin-Embedder-Policy[p883]`
- `Cross-Origin-Embedder-Policy-Report-Only[p883]`
- `Cross-Origin-Opener-Policy[p875]`
- `Cross-Origin-Opener-Policy-Report-Only[p875]`
- `Origin-Agent-Cluster[p873]`
- `Refresh[p1025]`
- `X-Frame-Options[p1024]`

MIME types §[p1408]

This section is non-normative.

The following MIME types are mentioned in this specification:

application/atom+xml
Atom [ATOM][p1410]

application/json
JSON [JSON][p1414]

application/octet-stream
Generic binary data [RFC2046][p1416]

application/microdata+json[p1384]
Microdata as JSON

application/rss+xml
RSS

application/x-www-form-urlencoded
Form submission

application/xhtml+xml[p1382]
HTML

application/xml
XML [XML][p1419] [RFC7303][p1416]

image/gif
GIF images [GIF][p1413]

image/jpeg
JPEG images [JPEG][p1414]

image/png
PNG images [PNG][p1415]

image/svg+xml

SVG images [SVG][p1417]

multipart/form-data

Form submission [RFC7578][p1416]

multipart/mixed

Generic mixed content [RFC2046][p1416]

multipart/x-mixed-replace[p1381]

Streaming server push

text/css

CSS [CSS][p1411]

text/event-stream[p1385]

Server-sent event streams

text/javascript

JavaScript [JAVASCRIPT][p1414] [RFC9239][p1416]

text/json

JSON (legacy type)

text/plain

Generic plain text [RFC2046][p1416] [RFC3676][p1416]

text/html[p1380]

HTML

text/ping[p1383]

Hyperlink auditing

text/uri-list

List of URLs [RFC2483][p1416]

text/vcard

vCard [RFC6350][p1416]

text/vtt

WebVTT [WEBVTT][p1418]

text/xml

XML [XML][p1419] [RFC7303][p1416]

video/mp4

MPEG-4 video [RFC4337][p1416]

video/mpeg

MPEG video [RFC2046][p1416]

References §[p14] [10]

All references are normative unless marked "Non-normative".

[ABNF]

Augmented BNF for Syntax Specifications: ABNF, D. Crocker, P. Overell. IETF.

[ABOUT]

The 'about' URI scheme, S. Moonesamy. IETF.

[APNG]

(Non-normative) *APNG Specification*. S. Parmenter, V. Vukicevic, A. Smith. Mozilla.

[ARIA]

Accessible Rich Internet Applications (WAI-ARIA), J. Diggs, J. Nurthen, M. Cooper. W3C.

[ARIAHTML]

ARIA in HTML, S. Faulkner, S. O'Hara. W3C.

[ATAG]

(Non-normative) *Authoring Tool Accessibility Guidelines (ATAG) 2.0*, J. Richards, J. Spellman, J. Treviranus. W3C.

[ATOM]

(Non-normative) *The Atom Syndication Format*, M. Nottingham, R. Sayre. IETF.

[BATTERY]

(Non-normative) *Battery Status API*, A. Kostiainen, M. Lamouri. W3C.

[BCP47]

Tags for Identifying Languages; Matching of Language Tags, A. Phillips, M. Davis. IETF.

[BEZIER]

Courbes à poles, P. de Casteljau. INPI, 1959.

[BIDI]

UAX #9: Unicode Bidirectional Algorithm, M. Davis. Unicode Consortium.

[BOCU1]

(Non-normative) *UTN #6: BOCU-1: MIME-Compatible Unicode Compression*, M. Scherer, M. Davis. Unicode Consortium.

[CESU8]

(Non-normative) *UTR #26: Compatibility Encoding Scheme For UTF-16: 8-BIT (CESU-8)*, T. Phipps. Unicode Consortium.

[CHARMOD]

(Non-normative) *Character Model for the World Wide Web 1.0: Fundamentals*, M. Dürst, F. Yergeau, R. Ishida, M. Wolf, T. Texin. W3C.

[CHARMODNORM]

(Non-normative) *Character Model for the World Wide Web: String Matching*, A. Phillips. W3C.

[CLIPBOARD-APIS]

Clipboard API and events, G. Kacmarcik, A. Snigdha. W3C.

[COMPOSITE]

Compositing and Blending, R. Cabanier, N. Andronikos. W3C.

[COMPUTABLE]

(Non-normative) *On computable numbers, with an application to the Entscheidungsproblem*, A. Turing. In *Proceedings of the London Mathematical Society*, series 2, volume 42, pages 230-265. London Mathematical Society, 1937.

[COMPUTEPRESSURE]

(Non-normative) *Compute Pressure*, K. Christiansen, A. Mandy. W3C.

[CONSOLE]

Console, T. Stock, R. Kowalski, D. Farolino. WHATWG.

[COOKIES]

HTTP State Management Mechanism, A. Barth. IETF.

[CREDMAN]

Credential Management, N. Satragno, J. Hodges, M. West. W3C.

[CSP]

Content Security Policy, M. West, D. Veditz. W3C.

[CSS]

Cascading Style Sheets Level 2 Revision 2, B. Bos, T. Çelik, I. Hickson, H. Lie. W3C.

[CSSALIGN]

CSS Box Alignment, E. Etemad, T. Atkins. W3C.

[CSSANIMATIONS]

CSS Animations, D. Jackson, D. Hyatt, C. Marrin, S. Galineau, L. Baron. W3C.

[CSSATTR]

CSS Style Attributes, T. Çelik, E. Etemad. W3C.

[CSSBG]

CSS Backgrounds and Borders, B. Bos, E. Etemad, B. Kemper. W3C.

[CSSBOX]

CSS Box Model, E. Etemad. W3C.

[CSSCASCADE]

CSS Cascading and Inheritance, E. Etemad, T. Atkins. W3C.

[CSSCONTAIN]

CSS Containment, T. Atkins, F. Rivoal, V. Levin. W3C.

[CSSCOLOR]

CSS Color Module, T. Çelik, C. Lilley, L. Baron. W3C.

[CSSCOLORADJUST]

CSS Color Adjustment Module, E. Etemad, R. Atanassov, R. Lillesveen, T. Atkins. W3C.

[CSSDEVICEADAPT]

CSS Device Adaption, F. Rivoal, M. Rakow. W3C.

[CSSDISPLAY]

CSS Display, T. Atkins, E. Etemad. W3C.

[CSSFONTLOAD]

CSS Font Loading, T. Atkins, J. Daggett. W3C.

[CSSFONTS]

CSS Fonts, J. Daggett. W3C.

[CSSFLEXBOX]

CSS Flexible Box Layout, T. Atkins, E. Etemad, R. Atanassov. W3C.

[CSSGC]

CSS Generated Content, H. Lie, E. Etemad, I. Hickson. W3C.

[CSSGRID]

CSS Grid Layout, T. Atkins, E. Etemad, R. Atanassov. W3C.

[CSSIMAGES]

CSS Images Module, E. Etemad, T. Atkins, L. Verou. W3C.

[CSSIMAGES4]

CSS Images Module Level 4, E. Etemad, T. Atkins, L. Verou. W3C.

[CSSINLINE]

CSS Inline Layout, D. Cramer, E. Etemad. W3C.

[CSSLISTS]

CSS Lists and Counters, T. Atkins. W3C.

[CSSLOGICAL]

CSS Logical Properties, R. Atanassov, E. Etemad. W3C.

[CSSMULTICOL]

CSS Multi-column Layout, H. Lie, F. Rivoal, R. Andrew. W3C.

[CSSOM]

Cascading Style Sheets Object Model (CSSOM), S. Pieters, G. Adams. W3C.

[CSSOMVIEW]

CSSOM View Module, S. Pieters, G. Adams. W3C.

[CSSOVERFLOW]

CSS Overflow Module, L. Baron, F. Rivoal. W3C.

[CSSPAINT]

(Non-normative) *CSS Painting API*, I. Kilpatrick, D. Jackson. W3C.

[CSSPOSITION]

CSS Positioned Layout, R. Atanassov, A. Eicholz. W3C.

[CSSPSEUDO]

CSS Pseudo-Elements, D. Glazman, E. Etemad, A. Stearns. W3C.

[CSSRUBY]

CSS3 Ruby Module, R. Ishida. W3C.

[CSSSCOPING]

CSS Scoping Module, T. Atkins. W3C.

[CSSSIZING]

CSS Box Sizing Module, T. Atkins, E. Etemad. W3C.

[CSSSCROLLANCHORING]

(Non-normative) *CSS Scroll Anchoring*, T. Atkins-Bittner. W3C.

[CSSSYNTAX]

CSS Syntax, T. Atkins, S. Sapin. W3C.

[CSSTRANSITIONS]

(Non-normative) *CSS Transitions*, L. Baron, D. Jackson, B. Birtles. W3C.

[CSSTABLE]

CSS Table, F. Remy, G. Whitworth. W3C.

[CSSTEXT]

CSS Text, E. Etemad, K. Ishii. W3C.

[CSSVALUES]

CSS3 Values and Units, H. Lie, T. Atkins, E. Etemad. W3C.

[CSSUI]

CSS3 Basic User Interface Module, F. Rivoal. W3C.

[CSSWM]

CSS Writing Modes, E. Etemad, K. Ishii. W3C.

[DASH]

Dynamic adaptive streaming over HTTP (DASH). ISO.

[DEVICEPOSTURE]

(Non-normative) *Device Posture API*, D. Gonzalez-Zuniga, K. Christiansen. W3C.

[DOM]

DOM, A. van Kesteren, A. Gregor, Ms2ger. WHATWG.

[DOMPARSING]

DOM Parsing and Serialization, T. Leithead. W3C.

[DOT]

(Non-normative) *The DOT Language*. Graphviz.

[E163]

Recommendation E.163 — Numbering Plan for The International Telephone Service, CCITT Blue Book, Fascicle II.2, pp. 128-134, November 1988.

[ENCODING]

Encoding, A. van Kesteren, J. Bell. WHATWG.

[EXECCOMMAND]

execCommand, J. Wilm, A. Gregor. W3C Editing APIs CG.

[EXIF]

(Non-normative) *Exchangeable image file format*. JEITA.

[FETCH]

Fetch, A. van Kesteren. WHATWG.

[FILEAPI]

File API, A. Ranganathan. W3C.

[FILTERS]

Filter Effects, D. Schulze, D. Jackson, C. Harrelson. W3C.

[FULLSCREEN]

Fullscreen, A. van Kesteren, T. Çelik. WHATWG.

[GEOMETRY]

Geometry Interfaces. S. Pieters, D. Schulze, R. Cabanier. W3C.

[GIF]

(Non-normative) *Graphics Interchange Format*. CompuServe.

[GRAPHICS]

(Non-normative) *Computer Graphics: Principles and Practice in C*, Second Edition, J. Foley, A. van Dam, S. Feiner, J. Hughes. Addison-Wesley. ISBN 0-201-84840-6.

[GREGORIAN]

(Non-normative) *Inter Gravissimas*, A. Lilius, C. Clavius. Gregory XIII Papal Bull, February 1582.

[HRT]

High Resolution Time, I. Grigorik, J. Simonsen, J. Mann. W3C.

[HTMLAAM]

HTML Accessibility API Mappings 1.0, S. Faulkner, A. Surkov, S. O'Hara. W3C.

[HTTP]

Hypertext Transfer Protocol (HTTP/1.1): Message Syntax and Routing, R. Fielding, J. Reschke. IETF.
Hypertext Transfer Protocol (HTTP/1.1): Semantics and Content, R. Fielding, J. Reschke. IETF.
Hypertext Transfer Protocol (HTTP/1.1): Conditional Requests, R. Fielding, J. Reschke. IETF.
Hypertext Transfer Protocol (HTTP/1.1): Range Requests, R. Fielding, Y. Lafon, J. Reschke. IETF.
Hypertext Transfer Protocol (HTTP/1.1): Caching, R. Fielding, M. Nottingham, J. Reschke. IETF.
Hypertext Transfer Protocol (HTTP/1.1): Authentication, R. Fielding, J. Reschke. IETF.

[INDEXEDDB]

Indexed Database API, A. Alabbas, J. Bell. W3C.

[INBAND]

Sourcing In-band Media Resource Tracks from Media Containers into HTML, S. Pfeiffer, B. Lund. W3C.

[INFRA]

Infra, A. van Kesteren, D. Denicola. WHATWG.

[INTERSECTIONOBSERVER]

Intersection Observer, S. Zager. W3C.

[RESIZEOBSERVER]

Resize Observer, O. Brufau, E. Álvarez. W3C.

[ISO3166]

ISO 3166: Codes for the representation of names of countries and their subdivisions. ISO.

[ISO4217]

ISO 4217: Codes for the representation of currencies and funds. ISO.

[ISO8601]

(Non-normative) *ISO8601: Data elements and interchange formats — Information interchange — Representation of dates and times*. ISO.

[JAVASCRIPT]

ECMAScript Language Specification. Ecma International.

[JLREQ]

Requirements for Japanese Text Layout. W3C.

[JPEG]

JPEG File Interchange Format, E. Hamilton.

[JSERRORSTACKS]

(Non-normative) *Error Stacks*. Ecma International.

[JSIMPORTATTRIBUTES]

Import attributes. Ecma International.

[JSJSONMODULES]

JSON Modules. Ecma International.

[JSRESIZABLEBUFFERS]

Resizable ArrayBuffer and growable SharedArrayBuffer. Ecma International.

[JSINTL]

ECMAScript Internationalization API Specification. Ecma International.

[JSON]

The JavaScript Object Notation (JSON) Data Interchange Format, T. Bray. IETF.

[LONGTASKS]

Long Tasks, D. Denicola, I. Grigorik, S. Panicker. W3C.

[MAILTO]

(Non-normative) *The 'mailto' URI scheme*, M. Duerst, L. Masinter, J. Zawinski. IETF.

[MANIFEST]

Web App Manifest, M. Caceres, K. Rohde Christiansen, M. Lamouri, A. Kostiainen, M. Giuca, A. Gustafson. W3C.

[MATHML]

Mathematical Markup Language (MathML), D. Carlisle, P. Ion, R. Miner. W3C.

[MEDIAFRAG]

Media Fragments URI, R. Troncy, E. Mannens, S. Pfeiffer, D. Van Deursen. W3C.

[MEDIASOURCE]

Media Source Extensions, A. Colwell, A. Bateman, M. Watson. W3C.

[MEDIASTREAM]

Media Capture and Streams, D. Burnett, A. Bergkvist, C. Jennings, A. Narayanan. W3C.

[REPORTING]

Reporting, D. Creager, I. Clelland, M. West. W3C.

[MFREL]

Microformats Wiki: existing rel values. Microformats.

[MIMESNIFF]

MIME Sniffing, G. Hemsley. WHATWG.

[MIX]

Mixed Content, M. West. W3C.

[MNG]

MNG (Multiple-image Network Graphics) Format. G. Randers-Pehrson.

[MPEG2]

ISO/IEC 13818-1: Information technology — Generic coding of moving pictures and associated audio information: Systems. ISO/IEC.

[MPEG4]

ISO/IEC 14496-12: ISO base media file format. ISO/IEC.

[MQ]

Media Queries, H. Lie, T. Çelik, D. Glazman, A. van Kesteren. W3C.

[MULTIPLEBUFFERING]

(Non-normative) *Multiple buffering*. Wikipedia.

[NAVIGATIONTIMING]

Navigation Timing, Y. Weiss. W3C.

[NPAPI]

(Non-normative) *Gecko Plugin API Reference*. Mozilla.

[OGGSKELETONHEADERS]

SkeletonHeaders. Xiph.Org.

[OPENSEARCH]

Autodiscovery in HTML/XHTML. In *OpenSearch 1.1 Draft 6*. GitHub.

[ORIGIN]

(Non-normative) *The Web Origin Concept*, A. Barth. IETF.

[PAINTTIMING]

Paint Timing, S. Panicker. W3C.

[PAYMENTREQUEST]

Payment Request API, M. Cáceres, D. Wang, R. Solomakhin, I. Jacobs. W3C.

[PDF]

(Non-normative) *Document management — Portable document format — Part 1: PDF*. ISO.

[PERFORMANCETIMELINE]

Performance Timeline, N. Peña Moreno, W3C.

[PERMISSIONSPOLICY]

Permissions Policy, I. Clelland, W3C.

[PICTUREINPICTURE]

(Non-normative) *Picture-in-Picture*, F. Beaufort, M. Lamouri, W3C

[PINGBACK]

Pingback 1.0, S. Langridge, I. Hickson.

[PNG]

Portable Network Graphics (PNG) Specification, D. Duce. W3C.

[POINTEREVENTS]

Pointer Events, J. Rossi, M. Brubeck, R. Byers, P. H. Lauke. W3C.

[POINTERLOCK]

Pointer Lock, V. Scheib. W3C.

[PPUTF8]

(Non-normative) *The Properties and Promises of UTF-8*, M. Dürst. University of Zürich. In *Proceedings of the 11th International Unicode Conference*.

[PRESENTATION]

Presentation API, M. Foltz, D. Röttsches. W3C.

[REFERRERPOLICY]

Referrer Policy, J. Eisinger, E. Stark. W3C.

[REQUESTIDLECALLBACK]

Cooperative Scheduling of Background Tasks, R. McIlroy, I. Grigorik. W3C.

[RESOURCETIMING]

Resource Timing, Yoav Weiss; Noam Rosenthal. W3C.

[RFC1034]

Domain Names - Concepts and Facilities, P. Mockapetris. IETF, November 1987.

[RFC1123]

Requirements for Internet Hosts -- Application and Support, R. Braden. IETF, October 1989.

[RFC2046]

Multipurpose Internet Mail Extensions (MIME) Part Two: Media Types, N. Freed, N. Borenstein. IETF.

[RFC2397]

The "data" URL scheme, L. Masinter. IETF.

[RFC5545]

Internet Calendaring and Scheduling Core Object Specification (iCalendar), B. Desruisseaux. IETF.

[RFC2483]

URI Resolution Services Necessary for URN Resolution, M. Mealling, R. Daniel. IETF.

[RFC3676]

The Text/Plain Format and DelSp Parameters, R. Gellens. IETF.

[RFC9239]

Updates to ECMAScript Media Types, M. Miller, M. Borins, M. Bynens, B. Farias. IETF.

[RFC4337]

(Non-normative) *MIME Type Registration for MPEG-4*, Y. Lim, D. Singer. IETF.

[RFC7595]

Guidelines and Registration Procedures for URI Schemes, D. Thaler, T. Hansen, T. Hardie. IETF.

[RFC5322]

Internet Message Format, P. Resnick. IETF.

[RFC6381]

The 'Codecs' and 'Profiles' Parameters for "Bucket" Media Types, R. Gellens, D. Singer, P. Frojdh. IETF.

[RFC6266]

Use of the Content-Disposition Header Field in the Hypertext Transfer Protocol (HTTP), J. Reschke. IETF.

[RFC6350]

vCard Format Specification, S. Perreault. IETF.

[RFC6596]

The Canonical Link Relation, M. Ohye, J. Kupke. IETF.

[RFC7034]

(Non-normative) *HTTP Header Field X-Frame-Options*, D. Ross, T. Gondrom. IETF.

[RFC7303]

XML Media Types, H. Thompson, C. Lilley. IETF.

[RFC7578]

Returning Values from Forms: multipart/form-data, L. Masinter. IETF.

[RFC8297]

An HTTP Status Code for Indicating Hints, K. Oku. IETF.

[SCREENORIENTATION]

Screen Orientation, M. Cáceres. W3C.

[SCSU]

(Non-normative) *UTR #6: A Standard Compression Scheme For Unicode*, M. Wolf, K. Whistler, C. Wicksteed, M. Davis, A. Freytag, M. Scherer. Unicode Consortium.

[SECURE-CONTEXTS]

Secure Contexts, M. West. W3C.

[SELECTION]

Selection API, R. Niwa. W3C.

[SELECTORS]

Selectors, E. Etemad, T. Çelik, D. Glazman, I. Hickson, P. Linss, J. Williams. W3C.

[SMS]

(Non-normative) *URI Scheme for Global System for Mobile Communications (GSM) Short Message Service (SMS)*, E. Wilde, A. Vaha-Sipila. IETF.

[STRUCTURED-FIELDS]

Structured Field Values for HTTP, M. Nottingham, P-H. Kamp. IETF.

[SRI]

Subresource Integrity, D. Akhawe, F. Braun, F. Marier, J. Weinberger. W3C.

[STORAGE]

Storage, A. van Kesteren. WHATWG.

[SVG]

Scalable Vector Graphics (SVG) 2, N Andronikos, R. Atanassov, T. Bah, B. Birtles, B. Brinza, C. Concolato, E. Dahlström, C. Lilley, C. McCormack, D. Schepers, R. Schwerdtfeger, D. Storey, S. Takagi, J. Watt. W3C.

[SW]

Service Workers, A. Russell, J. Song, J. Archibald. W3C.

[TOR]

(Non-normative) *Tor*.

[TOUCH]

Touch Events, D. Schepers, S. Moon, M. Brubeck, A. Barstow, R. Byers. W3C.

[TZDATABASE]

(Non-normative) *Time Zone Database*. IANA.

[UAAG]

(Non-normative) *User Agent Accessibility Guidelines (UAAG) 2.0*, J. Allan, K. Ford, J. Richards, J. Spellman. W3C.

[UIEVENTS]

UI Events Specification, G. Kacmarcik, T. Leithead. W3C.

[UNICODE]

The Unicode Standard. Unicode Consortium.

[UNIVCHARDET]

(Non-normative) *A composite approach to language/encoding detection*, S. Li, K. Momoi. Netscape. In *Proceedings of the 19th International Unicode Conference*.

[URL]

URL, A. van Kesteren. WHATWG.

[URN]

URN Syntax, R. Moats. IETF.

[UTF7]

(Non-normative) *UTF-7: A Mail-Safe Transformation Format of Unicode*, D. Goldsmith, M. Davis. IETF.

[UTF8DET]

(Non-normative) *Multilingual form encoding*, M. Dürst. W3C.

[UTR36]

(Non-normative) *UTR #36: Unicode Security Considerations*, M. Davis, M. Suignard. Unicode Consortium.

[WASMJS]

(Non-normative) *WebAssembly JavaScript Interface*, D. Ehrenberg. W3C.

[WCAG]

(Non-normative) *Web Content Accessibility Guidelines (WCAG)*, A. Kirkpatrick, J. O Connor, A. Campbell, M. Cooper. W3C.

[WEBANIMATIONS]

Web Animations, B. Birtles, S. Stephens, D. Stockwell. W3C.

[WEBAUDIO]

(Non-normative) *Web Audio API*, P. Adenot, H. Choi. W3C.

[WEBAUTHN]

Web Authentication: An API for accessing Public Key Credentials, M. Jones, A. Kumar, E. Lundberg, D. Balfanz, V. Bharadwaj, A. Birgisson, A. Czeskis, J. Hodges, J.C. Jones, H. Le Van Gong, A. Liao, R. Lindemann, J. Bradley, C. Brand, T. Cappalli, A. Langley, G. Mandyam, M. Miller, N. Satragno, N. Steele, J. Tan, S. Weeden, M. West, J. Yasskin. W3C.

[WEBCODECS]

WebCodecs API, C. Cunningham, P. Adenot, B. Aboba. W3C.

[WEBCRYPTO]

Web Cryptography API, D. Huigens. W3C.

[WEBDRIVER]

WebDriver, S. Stewart, D. Burns. W3C.

[WEBDRIVERBIDI]

WebDriver BiDi. W3C

[WEBGL]

WebGL Specifications, D. Jackson, J. Gilbert. Khronos Group.

[WEBGPU]

WebGPU, D. Malyshau, K. Ninomiya. W3C.

[WEBIDL]

Web IDL, E. Chen, T. Gu. WHATWG.

[WEBLINK]

Web Linking, M. Nottingham. IETF.

[WEBLOCKS]

(Non-normative) *Web Locks API*, J. Bell, K. Rosylight. W3C.

[WEBMCG]

WebM Container Guidelines. The WebM Project.

[WEBNFC]

(Non-normative) *Web NFC*, F. Beaufort, K. Christiansen, Z. Kis. W3C.

[WEBRTC]

(Non-normative) *Web RTC*, C. Jennings, F. Castelli, H. Boström, J. Bruaroey. W3C.

[WEBSOCKETS]

WebSockets, A. Rice. WHATWG.

[WEBTRANSPORT]

WebTransport, B. Aboba, N. Jaju, V. Vasiliev. W3C.

[WEBVTT]

WebVTT, S. Pieters. W3C.

[WHATWGWIKI]

The WHATWG Wiki. WHATWG.

[X121]

Recommendation X.121 — International Numbering Plan for Public Data Networks, CCITT Blue Book, Fascicle VIII.3, pp. 317-332.

[XFN]

XFN 1.1 profile, T. Çelik, M. Mullenweg, E. Meyer. GMPG.

[XHR]

`XMLHttpRequest`, A. van Kesteren. WHATWG.

[XKCD1288]

(Non-normative) *Substitutions*, Randall Munroe. xkcd.

[XML]

Extensible Markup Language, T. Bray, J. Paoli, C. Sperberg-McQueen, E. Maler, F. Yergeau. W3C.

[XMLENTITY]

(Non-normative) *XML Entity Definitions for Characters*, D. Carlisle, P. Ion. W3C.

[XMLNS]

Namespaces in XML, T. Bray, D. Hollander, A. Layman, R. Tobin. W3C.

[XMLSSPI]

Associating Style Sheets with XML documents, J. Clark, S. Pieters, H. Thompson. W3C.

[XPATH10]

XML Path Language (XPath) Version 1.0, J. Clark, S. DeRose. W3C.

[XSLT10]

(Non-normative) *XSL Transformations (XSLT) Version 1.0*, J. Clark. W3C.

[XSLTP]

(Non-normative) *DOM XSLTProcessor*, WHATWG Wiki. WHATWG.

Acknowledgments §[p14 20]

Thanks to Tim Berners-Lee for inventing HTML, without which none of this would exist.

Andersen, for their useful comments, both large and small, that have led to changes to this specification over the years.

Thanks also to everyone who has ever posted about HTML to their blogs, public mailing lists, or forums, including all the contributors to the various W3C HTML WG lists and the various WHATWG lists.

Special thanks to Richard Williamson for creating the first implementation of `canvas`[p661] in Safari, from which the canvas feature was designed.

Special thanks also to the Microsoft employees who first implemented the event-based drag-and-drop mechanism, `contenteditable`[p833], and other features first widely deployed by the Windows Internet Explorer browser.

Special thanks and $10,000 to David Hyatt who came up with a broken implementation of the adoption agency algorithm[p1278] that the editor had to reverse engineer and fix before using it in the parsing section.

Thanks to the participants of the microdata usability study for allowing us to use their mistakes as a guide for designing the microdata feature.

Thanks to the many sources that provided inspiration for the examples used in the specification.

Thanks also to the Microsoft blogging community for some ideas, to the attendees of the W3C Workshop on Web Applications and Compound Documents for inspiration, to the #mrt crew, the #mrt.no crew, and the #whatwg crew, and to Pillar and Hedral for their ideas and support.

Thanks to Igor Zhbanov for generating PDF versions of the specification.

Special thanks to the RICG for developing the `picture`[p334] element and related features; in particular thanks to Adrian Bateman, Bruce Lawson, David Newton, Ilya Grigorik, John Schoenick, Leon de Rijke, Mat Marquis, Marcos Cáceres, Tab Atkins, Theresa O'Connor, and Yoav Weiss for their contributions.

Special thanks to the WPWG for incubating the custom elements[p734] feature. In particular, thanks to David Hyatt and Ian Hickson for their influence through the XBL specifications, Dimitri Glazkov for the first draft of the custom elements specification, and to Alex Komoroske, Alex Russell, Andres Rios, Boris Zbarsky, Brian Kardell, Daniel Buchner, Dominic Cooney, Erik Arvidsson, Elliott Sprehn, Hajime Morrita, Hayato Ito, Jan Miksovsky, Jonas Sicking, Olli Pettay, Rafael Weinstein, Roland Steiner, Ryosuke Niwa, Scott Miles, Steve Faulkner, Steve Orvell, Tab Atkins, Theresa O'Connor, Tim Perry, and William Chen for their contributions.

Special thanks to the CSSWG for developing the worklets[p1181]. In particular, thanks to Ian Kilpatrick for his work as editor of the original worklets specification.

For about ten years starting in 2003, this standard was almost entirely written by Ian Hickson (Google, ian@hixie.ch).

As of 2015, Simon Pieters (Mozilla, zcorpan@gmail.com), Anne van Kesteren (Apple, annevk@annevk.nl), Philip Jägenstedt (Google, philip@foolip.org), and Domenic Denicola (Google, d@domenic.me), all previously long-time contributors, have joined Ian in editing the text directly.

Intellectual property rights §[p14 23]

The image in the introduction is based on a photo by Wonderlane. (CC BY 2.0)

The image of the wolf in the embedded content introduction is based on a photo by Barry O'Neill. (Public domain)

The image of the kettlebell swing in the embedded content introduction is based on a photo by kokkarina. (CC0 1.0)

The Blue Robot Player sprite used in the canvas demo is based on a work by JohnColburn. (CC BY-SA 3.0)

The photograph of robot 148 climbing the tower at the FIRST Robotics Competition 2013 Silicon Valley Regional is based on a work by Lenore Edman. (CC BY 2.0)

The diagram showing how `async`[p640] and `defer`[p640] impact `script`[p638] loading is based on a similar diagram from a blog post by Peter Beverloo. (CC0 1.0)

The image decoding demo used to demonstrate module-based workers draws on some example code from a tutorial by Ilmari Heikkinen. (CC BY 3.0)

The `<flag-icon>` example was inspired by a custom element by Steven Skelton. (MIT)

Part of the revision history of the `picture`[p334] element and related features can be found in the `ResponsiveImagesCG/picture-element` repository, which is available under the W3C Software and Document License.

Part of the revision history of the `theme-color`[p187] metadata name can be found in the `whatwg/meta-theme-color` repository, which is available under CC0.

Part of the revision history of the custom elements[p734] feature can be found in the `w3c/webcomponents` repository, which is available under the W3C Software and Document License.

Part of the revision history of the `innerText`[p163] getter and setter can be found in the `rocallahan/innerText-spec` repository, which is available under CC0.

Part of the revision history of the worklets[p1181] feature can be found in the `w3c/css-houdini-drafts` repository, which is available under the W3C Software and Document License.

Part of the revision history of the import maps[p1058] feature can be found in the `WICG/import-maps` repository, which is available under the W3C Software and Document License.

Part of the revision history of the navigation API[p919] feature can be found in the `WICG/navigation-api` repository, which is available under the W3C Software and Document License.
